He has taken soil structure as the all-important measure of fertility, for it is upon structure that aeration, water absorption and movement and, consequently, the growth and health of the plant depend; a good soil is a complex and balanced biological medium adequate for those micro-organisms that assist in all the physical and chemical changes concerned in nutrition. To understand what is meant by structure requires some comprehension of the forces that have produced the complete picture or profile upon which the fundamental systems of classification have been based. The relationship between genetic classification and productivity ratings is not always precise, but soil science is young and practical applications have so far outstripped fundamental studies. Hence, although the successful renovation of worn-out grasslands and rehabilitation of sea-flooded areas, for example, are based upon well-established principles in soil chemistry and physics, the reasons for the build-up or break-down of the mineral–organic aggregates or stable crumbs of a fertile soil are still somewhat speculative, and it is here that wrong management, quite as much as mismanagement, has assisted the erosion forces of Nature and where conservation services—but not nearly enough of them—are striving to redress the balance.

The author constantly stresses the relative stability of the 'plant-made' soil in contrast to that of the 'man-made' soil. That the latter may become many times more productive in certain situations is the result of the system of agriculture established through trial and error and the sensible adoption of modern aids in the form of better machines, better varieties and the fertilizers to improve and maintain fertility.

The well-chosen plates illustrate clearly the points in the text dealing with soil formation, structure, microbiology and conservation, and there is a short bibliography. One might criticize an occasional looseness in the nomenclature relating to nutrients, and there is an obvious slip at the top of p. 60; but the book is all but free of printing errors and is very well produced.

A. M. SMITH

TISSUE CULTURE

The Cultivation of Animal and Plant Cells

By Philip R. White. Pp. xii+239. (New York: The Ronald Press Company, 1954.) 6 dollars.

THE foreword states that this book was written with three objects: to describe the major techniques of plant and animal tissue culture in sufficient detail to enable them to be used in research, to present a group of simple methods suitable for teaching purposes and to emphasize "the essential importance of the cell itself, as the basic physiological entity".

While it is probable that few people can master an intricate technique like tissue culture merely by studying a book on the subject, it is very valuable to have the methods of leading experts recorded for the benefit of other workers in the field.

The book begins on a philosophical note with a discussion of the relationship of the cell to the organism. This is followed by an account of the history of cell culture, and in this connexion an interesting chart is provided tracing the various lines along which tissue culture has developed. It is unfortunate that the name of T. S. P. Strangeways is omitted from this summary, since he was one of the pioneers of the method in Europe and wrote two of the earliest books on the subject. The author deals next with the many different types of plant and animal cells that can now be grown *in vitro* and then proceeds to describe the tissue culture laboratory, its equipment, and routine procedures such as washing glassware and sterilization; succeeding chapters are devoted to nutrients and the preparation of various types of cultures. As he tells us in his foreword, Dr. White has been animated by the laudable ambition "to strip from the study of this subject [cell culture] its former atmosphere of mystery and complication", and the procedures he advocates are not unduly elaborate.

The difficult and controversial questions of how to measure growth and how to interpret the quantitative results obtained are considered at some length, and it is wisely emphasized that the observer must "take into account not merely the numerical data but also many qualitative features of the results which cannot be set down in numerical form". The last chapter, which deals with the various ways in which tissue culture can be applied in different medical and biological fields, is perhaps the most stimulating. In the reviewer's experience, so much attention is sometimes paid to developing and polishing the method that this tends to become an end in itself; it is therefore important to stress the fact that tissue culture is merely a technique, and useful only in so far as it is applied to the solution of biological problems.

Finally, there is an appendix in which are described some fairly simple experiments for beginners; an attempt has been made "to choose examples which are as simple as possible, so that they will not be beyond the means of small schools". This section should be useful for those wishing to organize courses in experimental biology for senior students.

A minor defect of the book is the considerable number of verbal slips which are encountered; for example, 'serum' when 'plasma' is meant (p. 200). The work can be recommended, however, as a clear and interesting account of some valuable methods; the more solid matter is enlivened here and there by some delightful quotations from ancient authors, which serve as texts for some of the chapters.

HONOR B. FELL

BELOW 1° K.

Magnetic Cooling

By C. G. B. Garrett. (Harvard Monographs on Applied Science, No. 4.) Pp. xi+110. (Cambridge, Mass.: Harvard University Press; New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1954.) 36*s*. net.

JUST over twenty years have elapsed since the temperature region below 1° K. was opened by the adiabatic magnetization of paramagnetic salts. Except for the war years there has been a steady increase in the work in this field, and the stage has now been reached where magnetic cooling is becoming a standard technique in many cryogenic laboratories. Comparing the progress of the magnetic cooling method with the state of gas liquefaction two decades after Cailletet and Pictet, there exists a strong resemblance which is reflected in Dr. Garrett's book. Now, just as then, the physical properties of the cooling agent completely hold the stage. Dr. Garrett is as preoccupied with the susceptibility of paramagnetic salts as the low-temperature physicists of the nineties were with the equation of state. The result is that his book seems a little out of balance, which is particularly noticeable in a short monograph of only 105 pages length. Detailed discussion of the paramagnetic phenomena is, at the present stage of development of magnetic cooling, certainly justified, but this means that "other experiments" had to be dealt with in eighteen pages. Rather more serious is the summary way in which the whole of demagnetization technique is treated in only eight pages. The sealed capsule method, for example, is not mentioned here at all. Description of experiments admittedly lacks the glamour of the theoretical discourse, but a monograph in applied science could have afforded slightly more space for technicalities at a time when the magnetic cooling method is being taken up by more and more laboratories.

While one may criticize the choice of balance in the book, it should be emphasized that the material has been treated competently and with clarity. The chapter on technique is followed by one on thermodynamic relations and one on the magnetic temperature scale. The following three chapters deal with the theory of paramagnetism at low temperatures, with the results of specific heats and susceptibilities for a number of salts and finally with co-operative effects. This section with its extensive set of references to original work will be found most useful by those who work in the field of adiabatic demagnetization or who are entering on it. A closing chapter gives a short survey of the use to which paramagnetic cooling has been put, such as investigations on liquid helium and on superconductors. Multi-stage demagnetization and nuclear alignment also receive here a short mention.

Subject to its limitations, the book will be of interest to most low-temperature physicists and to students specializing in either cryogenics or magnetism. It is unfortunate that the price will put it out of the reach of many of the latter.

K. MENDELSSOHN

SCINTILLATION COUNTERS AND PHOSPHORS

Scintillation Counters

By Prof. J. B. Birks. (Pergamon Science Series: Electronics and Waves.) Pp. viii+148+4 plates. (London: Pergamon Press, Ltd., 1953.) 21*s*.

THE development of scintillation counters in the past seven years is one of the most rapid contemporary advances in the techniques of nuclear physics, and Prof. J. B. Birks's book gives a timely summary of this recent work and a picture of the present state of the art.

The subject of these instruments is dealt with, not only from the point of view of those who wish to use them as tools, but also of those who are interested in the properties of the phosphors themselves. The author follows a logical sequence beginning with a brief but adequate summary of the principles of scintillation counting; this is followed by a discussion of photomultiplier tubes and data on the commercially available types. Measurements of instrumental resolution are then considered, and the next three chapters are devoted to descriptions of the various types of phosphors. The final section is a survey of some applications of scintillation counters.

Prof. Birks's main interest has been the study of organic crystalline phosphors, and the section on these materials forms the longest single chapter in the book. This is a comprehensive account including results of recent work by the author, and his interpretation of these results in terms of the 'photon exchange' process which he has proposed as an alternative theory to the 'exciton migration' process as a mechanism of energy transfer in mixed crystals. One wonders whether a monograph, particularly with the present title, is the best place for the detailed presentation of such a theory, at least until there is general agreement on its tenets. As one concerned with the use of counters, the reviewer would have preferred to see a greater proportion of the space devoted to discussion of problems likely to arise in the applications of the instruments. For example, to anyone wishing to use the fast response of these counters to their best advantage, a fuller indication of the circuit problems met with in the millimicrosecond region would be a welcome addition. A description of experimental methods of crystal production would also be useful.

Prof. Birks has, however, written a very readable book and he has included a good bibliography which will be useful to the reader interested in further experimental details.

The publishers are to be congratulated upon the speed with which the book was produced, an essential requirement for a monograph in a rapidly developing subject: very few misprints occur, and the diagrams and type are pleasing.

A. R. CRATHORN

DISTRIBUTION OF MINOR ELEMENTS IN ROCKS

RESEARCH on the geochemistry of the rarer elements was given a real impetus in the 1930's by the investigations of the late V. M. Goldschmidt and his co-workers. Progress at that time was due, in the main, to the introduction and application of sensitive methods of instrumental analysis. Except for the period of the war years, interest and investigation on the geochemistry of the rare elements has continued to grow, and the recent discussion at Oxford arranged by Section C (Geology) of the British Association reflected in several respects the progress which has been made during the past few years. The programme of speakers and discussion was arranged so as to cover the distribution of minor elements in a broad way, starting with aspects of cosmochemistry and followed by consideration of minor element behaviour of igneous rock series, sedimentary rocks and finally metamorphic rocks. In his introductory remarks, the chairman, Prof. L. R. Wager (University of Oxford), pointed out that once geochemical patterns of minor element-behaviour were firmly established for known conditions—as, for example, in fractionated rock sequences—they could no doubt be used in solving more complex geological problems of rock genesis where processes are less clear.

Dr. L. H. Ahrens (University of Oxford) directed attention to the general qualitative similarity of composition of various materials composing the observable universe. He pointed out, however, that it is only the earth and the meteorites which can be sampled directly and are capable, therefore, of precise quantitative investigation: this opens up the possibility of testing exact quantitative equivalence of composition. Evidence of such equivalence would be of geochemical, geophysical, petrological and nuclear-physical significance. Tests could be carried out by examining pairs or larger groups of elements, provided they show a high degree of geochemical coherence: zirconium–hafnium; niobium–tantalum; some rare earths and potassium–rubidium were cited as possibilities. Adequate data are available only for the pair of alkali metals, and their association in the commonest rocks and meteorites were discussed in detail. Earlier investigations of Ahrens, Pinson and Kearns[1] indicated that the ratio potassium/rubidium remains uniform throughout the principal types of rock and is very similar or possibly equal to that in chondrites, the commonest meteorites. Their observations were restricted mainly to North American rocks, and evidence from other sources was therefore desirable. Some seventy new determinations, mainly on igneous rocks from South Africa, have since been made and all observations are represented in Fig. 1. The close association of potassium and rubidium in rocks and meteorites is evident, and calculation shows that the ratios of potassium to rubidium for rocks and chondrites are equal to within about 5 per cent. Dr. Ahrens pointed out that as neither element is a participant of either metal or sulphide phases, it can be concluded similarly that the ratio of potassium to rubidium for the earth is equal to that for meteorites ± 5 per cent. This is the first, and so far only, example of its kind and has been taken as evidence in support of a common origin for the earth and meteorites. This information does not, however, appear to be of use with regard to the problem of two possible origins of the meteorites—either from a shattered planet or from a collision of asteroids. It is desirable that similar research be carried out on other possible pairs or groups of elements. Sir Edward Bailey commented on the analogy between the ratio of potassium to rubidium and the ratios of various isotopes of different elements in the earth and meteorites which observation has shown to remain uniform. Prof. Wager and Dr. M. H. Hey commented on the fact that Dr. Ahrens's data apparently show that different parts of the earth may be characterized by slight but significant differences in their potassium–rubidium ratio and that this is perhaps the first and only reliable indication of any fundamental regional differences.

Dr. S. R. Nockolds (University of Cambridge) described some of the results of recent research at Cambridge. The principal objects of these investigations were to examine the behaviour of trace elements with respect to the major constituent elements in some well-described igneous rock series of calc-alkali, alkali and tholeiitic character: to determine how their behaviour varied from series to

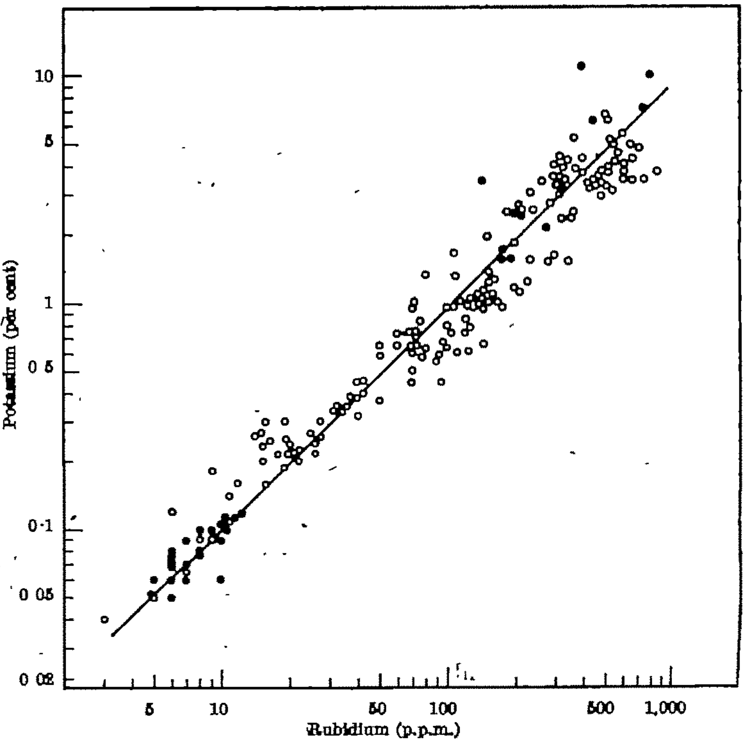

Fig. 1

series and from group to group and to see what light, if any, they might throw on the origin of the three main branches of igneous rock evolution. Particular attention was given to the calc–alkali and alkali groups, which were represented as follows: (calc–alkali) southern California batholith, the Scottish Caledonian and lavas of Lassen Peak, Crater Lake, Lesser Antilles, the Medicine Lake Highlands and Sierra Nevada; (alkali) Scottish Tertiary, Hawaiian alkali rocks, Polynesian alkali series, and the latite series of Sierra Nevada.

Discussion was confined to lithium, chromium, nickel, cobalt, iron and vanadium, some data on which have already been published[1,2]. For the purpose of demonstrating behaviour, the concentration of each element is related (as ordinate) to the function $[(\frac{1}{3}Si + K) - (Ca + Mg)]$, as suggested by Larsen. The characteristic behaviour of chromium and nickel—a regular and sometimes sharp decrease of concentration with increase in acidity, followed by some levelling—is clearly evident in nearly all examples of a series from each of the three groups. Iron and vanadium behave in much the same way in series of calc–alkali rocks; the concentrations of both decrease regularly with acidity. A similar behaviour is sometimes shown by iron in the alkali rocks, although the amount often remains fairly uniform over a considerable range of low $[(\frac{1}{3}Si + K) - (Ca + Mg)]$ values. Vanadium, on the other hand, invariably increases with increase in the magnitude of the function, passes through a maximum and then decreases regularly with increase in the magnitude of the function. As anticipated, lithium invariably increases with decrease of $[(\frac{1}{3}Si + K) - (Ca + Mg)]$ in all series from each group. Cobalt often follows magnesium, particularly in the calc–alkali rocks, and sometimes iron. Behaviour patterns in the calc–alkali series are often similar to rock series classed as belonging to the tholeiitic group. Dr. Nockolds finally directed attention to recent investigations on hybrid rocks, and it was shown that, unlike the igneous rocks of a series, variation of concentration is linear in respect to the function $[(\frac{1}{3}Si + K) - (Ca + Mg)]$. During discussion of a point raised by Dr. W. Campbell-Smith, Dr. Nockolds stated that the data on the rock series are evidence in support of crystal fractionation.

In a discussion on the distribution of elements in sedimentary rocks, Dr. J. R. Butler (Rothamsted Experimental Station) referred first to the transportation of elements to the oceans, either as ions (simple or complex), as constituents of or associated with colloids, or as constituents of detrital material. The ionic potential (the ratio of ionic charge to ionic radius) of Cartledge as used by Goldschmidt can be used as a starting-point for classifying elements according to their tendency to occur in aqueous solutions as cations or anions, or to be precipitated as hydrolysates. Lead, however, can be transported as a complex ion, and in a discussion which followed it was pointed out that several of the poorly shielded cations (as defined by Ahrens[4])—Au^+, Hg^{2+}, Cu^{2+} and Pt^{2+}, for example—are likely to be transported as stable complexes depending, of course, on *p*H, composition of the waters and other factors. In a reducing environment, such agencies as hydrogen sulphide may bring about precipitation of a sparingly soluble sulphide (Ag_2S or Cu_2S, for example) provided the solubility product can be exceeded and provided a complex can be broken; the complex AuS^- is particularly stable in this respect.

The significance of cation hydration was emphasized by considering the alkali metals. Degree of hydration is determined mainly by size. It was pointed out that available evidence for the pair Cs^+ and K^+ (radii 1·67 and 1·33 respectively) indicates that the ratio of cæsium to potassium is greater in shale than in igneous rocks; further fully quantitative investigations are, however, required to verify this. Dr. Butler suggested that a critical examination of the cæsium to potassium ratio might prove to be helpful in the problem of the origin of glauconite. The importance of illite as a constituent of argillaceous sediments was stressed. Unlike other clay minerals, illite can provide inter-sheet structure sites of potassium for camouflage of rubidium and cæsium.

Gallium, chromium, cobalt, copper, zinc, tin, lead, zirconium and the alkali earths were discussed in addition to the alkali metals. When contrasting the abundance of gallium in igneous rocks (15 p.p.m.) with the value of 50 p.p.m. for shale, Dr. Butler pointed out that although interesting conclusions can be derived on the basis of these figures, the latter come from different sources, and as different analytical procedures have been used they are not strictly comparable. The danger of comparing data from different sources was strongly endorsed by those participating in the discussion. Available data should be used with extreme caution and there is a great need for improving the quality of future determinations.

Prof. F. J. Turner (University of California) emphasized the fact that whereas considerable data are now available on igneous rocks in particular, and sedimentary rocks to a lesser extent, quantitative data on the metamorphic rocks are conspicuously lacking. This has led to much speculation on patterns of behaviour and their possible geological significance in the metamorphic terranes. Thus, for example, Sahama[5] has observed in a reconnaissance investigation that the boron concentration in serpentine is much higher than that in parent peridotite; this suggests the action of sea water as a cause for boron enrichment, as it contains appreciable boron. Prof. Turner concluded that provided large samples are examined, departure from ideal iso-chemical metamorphism is rarely profound in the case of the common elements. It was felt, however, that concentrations of the trace elements are more likely to show large variations. He referred to the earlier reconnaissance work of Sahama[5] and Shaw[6], which indicated iso-chemical metamorphism with respect to several of the minor elements. He then considered from a theoretical point of view the possible patterns of behaviour which may be found when data become available, and dealt briefly with the only two exhaustive investigations known to him, neither of which has yet been published. The first of these is an investigation by A. E. Engel and Celeste Engel (California Institute of Technology) on progressively metamorphosed rocks of the Grenville Series in the Adirondacks, which indicates trends different from the earlier work; for not only do elements such as strontium, lead, manganese and chromium appear to be added to some beds and removed from others, even when there is no indication of general metasomatism or magmatic influence, but also isotope composition varies. The second detailed work is that of Pitcher and Sinha (Imperial College of Science and Technology, London), who have analysed several series of bulk samples taken across a pelitic hornfels formation in a contact aureole in Donegal. In profiles of 1,500 ft. in length taken normal to the contact, the mean composition of all samples was found to remain the same. The formation had remained a closed system and there appeared to be no metasomatism; metamorphic differentiation had, however, occurred along each profile and compositional gradients had been set up.

A general impression left by the discussion on the distribution of minor elements was that most investigations nowadays involve far more analyses than heretofore; this is a healthy development. There is no doubt that a vast amount of fresh and exciting information remains to be unearthed, but real progress will only be achieved by combining quality with quantity.

ANIMAL POPULATIONS AND FORESTRY

AT the recent meeting in Oxford, Sections D (Zoology) and K* (Forestry) of the British Association held a combined symposium under the chairmanship of Prof. L. W. Grensted to discuss animal populations with reference to British forestry. Mr. G. H. Thompson, of the Department of Forestry, University of Oxford, opening the symposium with a general introduction, reviewed briefly some of the more important forms of injury caused by animals at different stages in the life of a forest. Insects, rabbits, squirrels, mice and voles often severely damage seed and young trees. In older forests the chief pests are insects, particularly those feeding on foliage. Conifers have a smaller capacity for regenerating lost foliage than broad-leaved trees, yet in Great Britain defoliating insects have so far killed comparatively few conifers. The British fauna includes species, such as the nun moth and pine noctuid, that are important pests of conifers on the Continent of Europe, but which in Britain have so far remained uncommon: the reason for their scarcity is unknown. The pine looper (*Bupalus piniarius* L.), although usually a common moth, first reached epidemic numbers in 1953 at Cannock Chase, completely defoliating 120 acres of Scots pine and severely attacking a much larger area. A similar attack in 1954 would almost certainly produce heavy tree mortality. Non-lethal degrees of defoliation presumably reduce growth increment, but no data exist.

Trees weakened by drought or defoliation, or unthrifty owing to unsuitable site conditions or old age, are susceptible to attack by insects such as wood-wasps and certain bark-beetles which cannot successfully oviposit in healthy vigorous trees. At Cannock Chase the defoliated pine are entered by a bark-beetle (*Myelophilus piniperda* L.), the tunnels of which in the cambium girdle and kill trees that might recover if protected from further loss of foliage. It is often hard to decide whether an insect species feeds exclusively on weakened trees, because of the difficulty of defining health.

Apart from safeguarding future vigour by choosing tree species suited to the sites to be planted, the forester may attempt to prevent or reduce animal injury by sylvicultural, biological or by chemical means. His choice of methods should be based on ecological knowledge, and in particular of those factors limiting population numbers. In fact, little is known of the population dynamics of even the more important forest pests. The science is new, and population studies are very time-consuming; the collection of data for even a dozen species of insect and three species of mammal is a formidable task. Climate, predators and parasites, and food supply are probably the chief factors influencing animal numbers. Past freedom from epidemics of coniferous defoliators may have been due to the absence of large blocks of forest of an appropriate age-class.

The application of insecticides may be justifiable to save a tree crop otherwise doomed; but, apart from the expense and impermanence of treatment, the biological implications are not fully understood, and the pest may ultimately benefit by destruction of its associated parasites and predators, or resistance to the insecticide may be developed. Forest practice should aim at keeping the injurious animal fauna below the level at which economic damage occurs by biological and sylvicultural methods; and to achieve this objective detailed knowledge is required of the factors affecting animal numbers.

Mr. F. A. Courtier, of the British Forestry Commission, described studies recently initiated to determine a satisfactory method of estimating grey squirrel populations in order that the efficacy of control measures may be assessed. A native of North America, the grey squirrel was first observed in Great Britain in 1828 and has since spread to almost every county. It is most injurious in forests, particularly to broad-leaved trees, girdling and killing stems at ground-level and also destroying leading shoots. Barking usually occurs in late spring or early summer when sap-flow is most active. There are two main breeding periods—December–January and May–June. The restricted breeding periods and relatively long time—ten weeks—spent by the young in the drey offer excellent opportunities for control.

Visual counts of adults have not given comparable results under varied woodland conditions. The relationship between the number of the breeding and the sheltering type of drey and the size of the squirrel population is being studied in mature oak woodland.

Courtier referred to estimates of population by the capture–recapture method being undertaken by Monica Shorten in an isolated wood that offers seasonal variation in food; this produces a more settled squirrel population. After intensive trapping, marking and release, the area is cleared of dreys and as many squirrels as possible are killed. Records of marked squirrels shot also provide information concerning their movements.

The squirrel population on a small area in Alice Holt forest is being studied for a period of years. Permanent trapping sites have been established. After pre-baiting for five days, trapping is conducted for four consecutive days; this procedure is repeated at intervals of six weeks. Trapped squirrels are marked and released after recording sex, weight, breeding condition, injuries and moult-stage. The squirrels show little fear of the traps and appear not to travel far, almost all recaptures being in the original traps. Twelve nesting-boxes have recently been erected to provide information on young squirrels and their ultimate dispersal.

Mr. H. N. Southern, of the Bureau of Animal Population, University of Oxford, dealt with fundamental population studies of two of the commonest deciduous woodland rodents, the wood mouse (*Apodemus sylvaticus* L.) and the bank vole (*Clethrionomys glareolus* Schreb.). These two species probably play an important part in preventing forest regeneration, but little is known about the control of their numbers. The first step in studying this problem is to know what numbers are present and how many are born and die every year. The best available method is live-trapping. A proportion of the population is caught, marked with numbered leg-rings and released. Later, another trap sample is taken to determine the proportion of marked to unmarked animals, and so the number present at the original marking can be calculated. An extension of this method from a series of trappings also gives information on the numbers coming into and leaving the population during each interval. The statistical problems involved in this kind of calculation have been recently discussed by Chitty and Leslie, and under optimum conditions estimates should be accurate to within 10 per cent. However, serious errors may be introduced by the marked animals entering the traps more readily than the unmarked ones. This complication is still being studied.

Preliminary results from continuous trappings on 250 acres of woodland between 1948 and 1952 suggest that the trappable population of both rodents varies between 5 and 25 per acre according to season. But there are other more interesting variations. During the first year both species reached a peak in autumn; in the second year wood mice failed to reach an autumn peak; in the third year both species failed to reach an autumn peak; in the final year both species were recovering from this decline in numbers. It is interesting to note that the tawny owls (*Strix aluco* L.) which were preying on these rodents, and whose population was also being studied, showed repercussions. In the first year they preyed mostly upon wood mice; in the second year they changed to bank voles when the wood mice declined; in the third year—when both prey species were at their lowest ebb—the owls practically failed to rear any young because of food shortage.

These preliminary results illustrate the labour which will be needed to obtain a true idea of the balance of interrelationships between members of an animal community. Only when these fundamental problems are thoroughly understood will it be possible to predict, and perhaps prevent, economic catastrophes instead of resorting to *ad hoc* measures to palliate damage already done.

Dr. Myles Crooke, of the Forestry Commission, described a survey conducted in Britain during the winter of 1953–54 into the status of the pine looper (*Bupalus piniarius*) in all the State pine forests considered to be susceptible to attack. The survey was a sequel to the pine looper epidemic at Cannock Chase in 1953. The moth has an annual life-cycle: adults are in flight from May until July and the larvæ feed until October or later before descending into the litter layer to pupate. The survey was extensive in design and was based on counts of number of pupæ found in quadrats one yard square. At low populations the insects are uniformly distributed and a sampling intensity of 0·005 per cent is considered satisfactory. This is achieved by assessing five quadrats in about one out of every ten compartments in a forest. The intensity of sampling is increased when populations are high. For example, at Cannock Chase every compartment of suitable age was sampled, using as many as fifty quadrats per compartment. Four population zones were discernible: (1) defoliation complete: more than 150 pupæ per sq. yd.; (2) defoliation severe: 80–150 pupæ per sq. yd; (3) defoliation not serious: 40–80 pupæ per sq. yd.; (4) no apparent defoliation: less than 40 pupæ per sq. yd.

On the Continent of Europe, where intensive sampling over a small area is employed, the endemic population-level is considered not to exceed 0·1 pupæ per square metre: a mean of six or more pupæ per square metre carries the threat of obvious defoliation the following summer. The British survey shows that many forests exhibit considerably higher pupal counts than this. It would seem that either a much higher endemic level can be maintained under British conditions, or that pine looper populations are on the increase and epidemics similar to that at Cannock may be expected elsewhere. No underlying cause, such as recent climatic change, is apparent to support the latter hypothesis.

The normal range of population fluctuations, capacity for increase and limiting factors of the pine looper require investigation. Meanwhile, the survey has proved of immediate value in indicating areas where control measures are necessary.

Prof. G. C. Varley, of the Hope Department of Entomology, University of Oxford, discussed long-term studies, started in 1949, of the winter moth and other species the larvæ of which defoliate oak trees. This research is currently supported by a grant from the Nature Conservancy. In order to assess the effects of climatic factors and of predators and parasites it is necessary to estimate the population densities of the species concerned as frequently as possible and to understand the life-cycles of the commoner parasites and predators. Some forest insects, like the winter moth, are particularly easy to study: they spend the early summer in the larval stage feeding upon the young leaves of oak, where they can be sampled. From these samples some idea of the effects of parasites and predators can be gained. They then spin to the ground on a silken thread and can be intercepted by traps covering a known area. A detailed investigation of this sample provides an estimate of the factors killing full-grown larvæ.

A census is made of the winter moth adults by trapping a sample as they ascend the trees in November or December. The results can be expressed in the form of a table showing the successive causes of mortality and their percentage. The largest percentage destruction takes place between the time of adult emergence and the appearance of the well-grown caterpillars. The percentage of survival of the eggs presumed to be laid on the trees has been found to vary considerably from tree to tree. On trees which open their buds early some 10 per cent of the expected number of caterpillars can be discovered; but on trees which flush late only 2 per cent of the expectation is found. This is partially due to the dispersal of caterpillars when they first enter oak buds. In windy weather they are blown considerable distances on threads of gossamer and can be trapped at a high level between the tree tops on sticky traps. The inability of the winter moth to establish itself in trees which open late suggests that it may be possible to choose strains of oak which may be genetically resistant to this form of damage.

Curiously enough, under those trees which open their buds early the heavy caterpillar population suffers proportionately greater destruction when it enters the pupal stage. This may be due to differential attack by predatory animals such as shrews or small rodents in the soil.

At first sight, parasites seem to be relatively unimportant: they kill some 30 per cent at most of the caterpillars of the winter moth. Similar investigations of other caterpillar species have shown approximately the same degree of parasitism. This might be interpreted as an indication that parasites have little effect on caterpillar numbers. However, since many parasites are specific, this explanation would appear to be incorrect. If a specific parasite of an uncommon host is to maintain its numbers it must be extremely efficient at searching for the favoured host. This suggests that the relatively high efficiency of specific parasites may be the basic factor which keeps their hosts to the status of uncommon species, whereas the winter moth and green tortrix, attacked as they are by far less efficient parasites, remain regular pests of great economic importance.

In discussion, Mr. M. V. Laurie, of the Forestry Commission, pointed out that the pine looper has avoided Corsican pine at Cannock Chase. Dr. E. W. Jones, of Oxford, remarked that wood pigeons and squirrels are sometimes the major destroyers of acorns. He also described preferential feeding by mice on acorns from three trees. Analysis showed that the acorns from the preferred tree had the highest sugar and lowest tannin content. Dr. K. R. S. Morris, of the Nature Conservancy, suggested that destruction of carnivores may be largely to blame for upsetting Nature's balance and emphasized that many animals serve a dual purpose: for example, mice distribute seed as well as destroy it.

The chairman, in summing up, said that the papers read had shown that it is the healthy balance in the body corporate which is the fundamental problem.

G. H. Thompson

FACTORS CONTROLLING BIOLOGICAL MULTIPLICATION

On September 24 and 25, the Institute of Biology, with the idea that different fields of investigation often gain from a joint discussion of their results and problems, arranged a symposium on "The Numbers of Man and Animals". The symposium was opened by Sir Alexander Carr-Saunders and he stressed the need for caution in applying the results in one field to the problems of another. There was much vigorous discussion between people of dissimilar training; it demonstrated that the warning had been unnecessary or that it had been heeded. Discussion was greatly helped by the circulation of the papers before the meeting. Most authors assumed, and the assumption seemed to be justified, that their papers had been read; they therefore introduced them with only a brief résumé of the main conclusions and then waited for the argument.

Economics and mathematics dominated the first session. Mr. A. T. Peacock discussed "Economic Theory and the Concept of an Optimum Population". He doubted whether we could predict accurately enough the consequences of changing the size of a population for it to be wise to take any active steps to promote such a change; he therefore thought the proposals to diminish Britain's population from 50 to 25 million were misguided. He also doubted the value of the concept of an optimum population, but not sufficiently emphatically to satisfy Mr. F. Le Gros Clark, who felt that people who are considering the effects of different sizes of market on production often overlook the fact that much of what is produced could be dispensed with without detriment, and perhaps even with advantage, to the community. Several speakers in the discussion pointed out that even if the concept had reality, the ideal size must depend on whether we are trying to arrange for comfort in peace or safety in war, and that many economic arguments are trimmed to suit the supposed requirements of strategy. The uncertainty of forecasts about human populations was the theme of Prof. E. Grebenik's paper; he said that forecasts are at least consistent in one thing—they all prove wrong. The main reason for this, he said, is the incursion of new factors such as sanitation and contraception, which affect numbers in opposite but not always equal ways. Contraception was the main theme of the discussion, and the readiness with which the governments and women of Japan and India accepted it was contrasted with the official obstruction of the Catholic hierarchy and the Communist Party. The attitude of the latter was epitomized by a quotation from the recent United Nations population congress in Rome: "The government of the U.S.S.R. does not believe in fitting population to resources but in fitting resources to population". The widely different attitude of people in different parts of the world was also shown by Prof. I. Schapera in a paper on the position in the Bechuanaland Protectorate which was presented but not discussed because of the absence of the author. The Kgatla hold that it is unjust and ridiculous that a woman should not have a child as often as is compatible with the welfare of any existing children, and the Protestant ethic, which is officially held by many of them, has undergone some consequent modification. Sir Charles Darwin looked on contraception as a palliative, and did not think that either it or the awareness of the danger would keep world population from pressing alarmingly on world resources.

Mr. J. G. Skellam's paper on "The Mathematical Approach to Population Dynamics" provoked a discussion on the relative merits of mathematics and observation, although the author had said that they work best when working hand-in-hand and that modern computing machinery can cope with problems approaching the complexity of actual experimental, even if not natural, conditions. He argued that many ecological experiments are foredoomed to failure by the predictable chance of random extinction because the colonies are so small. Mr. M. E. Solomon pointed out that the rigid mathematical formulation of a hypothesis has the merit that it forces attention on to the component parts of the hypothesis and so might reveal methods of testing not apparent from a verbal statement.

In the next session, Dr. D. Lack gave examples of the types of factor that control the density reached by different species of animal, and he showed that generalization from one species to another is hazardous. In wild populations, reproductive rate is mainly controlled by food shortage, predation, and disease. These factors interact and the position is still further complicated by the effect, on predation of one species, of variations in the numbers of an entirely different alternative food species. Dr. D. H. Chitty brought out a different aspect of the problem by describing striking physiological differences, which are apparently transmitted to the young, between voles maintained under different conditions of crowding and intraspecific strife. It has for long been apparent that neither food shortage nor disease gives an adequate explanation of the periodic 'crashes' in the numbers of wild voles. The new factor is that voles in stable and in rapidly expanding communities differ in rate of growth and in the weights of such organs as spleen, adrenal and testis; there is therefore no need for us to be surprised if their reproduction- and survival-rates are widely different too. Prof. T. Park described his extremely comprehensive experiments on interspecific competition using two similar species of flour beetle, *Tribolium confusum* and *T. castaneum*. From them it appeared that the successful species need not be the one that in isolation would have reached the greatest density, that the change which ultimately would lead to the extinction of one species probably took place early in the association, and that the permanent co-existence of two species which compete is improbable. One environment, flour, was used and six climates in which the temperature varied from 24° to 34° and the humidity from 30 to 70 per cent; these affected the species differently, so that sometimes one and sometimes the other prevailed.

Although Park had said, "Most probably, if causation were better understood for control cultures, the usual, and unusual, events seen in experimentals could be more accurately forecast", much of the discussion turned on the extent to which the concept of a random event, for example, the random extinction of a species, has any value. If events are random in a fully controlled environment, then, as one speaker put it, "the beetles were just being used to work out sums"; if not, the important feature is to ascertain the precise nature of the competition and the mechanism by which one species eliminates the other. Several speakers mentioned other species in which crowding affects physiology; for example, *Eurygaster* was quoted by Prof. J. B. Cragg as living on wheat for as long as its numbers are increasing but on other plants during the phase of decline.

In the third session, the symposium started with man before moving on to his domestic animals. Prof. A. L. Banks surveyed the history of disease control in Britain and other countries and, taking *festina lente* as his motto, urged the need for caution before upsetting the established customs of other countries by the immediate introduction of our public health measures. His plea that "No matter what new discoveries are made in the future, whether they include a 'cure-all' for disease, or a simple method of preventing conception, action on a large scale should be withheld until all the implications have been fully thought out", demands perhaps too much *lente* when we consider that the consequences of a single change in a laboratory colony of *Tribolium* have not yet been fully thought out. There was, however, general agreement with his strictures on the Olympian use of the word 'we'. The motives that lead people to decide that 'we' will do something for or to a less developed community have in the past been fear, altruism and economic needs. These motives are still with us; they vary in acceptability; but, whatever the motive, there is little chance of a successful and stable result unless local opinion understands the activity and co-operates in it.

From the chair, Prof. J. Z. Young urged speakers not to be apocalyptic, but to remember that at each stage of history thoughtful people had maintained that the world was in a very unpromising condition. Dr. F. Fraser Darling thought they had probably been right, and commended a Brahman who released trapped rats during a plague epidemic; but most contributors to the discussion had a more optimistic outlook. Mr. Le Gros Clark stressed that a community that has been freed from the most debilitating diseases, even if it does in consequence have occasional famines, will, for physical reasons, recover from them better than one that is still debilitated; and also, as Dr. C. Gordon put it, "because they are people who are aware of having been well". For each reason, in the fit of anger that is likely to succeed the famine, they are more likely to do something about the causes that led to it.

Dr. A. S. Parkes dealt vividly with the research that is being done on contraception, on the factors that affect the sex ratio in man and animals, and on the preservation of sperm by freezing. Present-day contraceptive methods are inefficient anachronisms, and he surveyed the various possible modes of approach, stressing the advantages of finding something that would, when eaten, inhibit spermagenesis or ovulation. He was, however, unconvinced that any of the plant extracts used by primitive peoples have a significant contraceptive effect. Work on the third problem may be of great short-term importance in solving the first, because the successful preservation of human sperm goes far to offset the irreversibility that has hitherto been the primary objection to vasectomy as a mode of contraception.

Dr. P. S. Henshaw, Sir Charles Darwin and Mr. E. M. Nicholson stressed the point that, whether a community wishes larger or smaller numbers, the wish cannot become effective until we know more about the processes of fertilization and implantation. They contrasted the importance of this work with the niggard support coming from public funds. In suitable circumstances, venery and fecundity are each commendable, but they are separate human activities and the breaking of their historically necessary association is long overdue.

Human communities with a high standard of living tend to have low birth-rates, whereas the opposite is true of domestic animals. The reasons for this apparent contradiction were considered by Dr. J. Hammond and others. No definite conclusion was reached in the discussion, but it appeared that the effect in animals is physiological whereas in man it is the consequence of associated social and cultural changes; where improved nutrition does not lead to these changes, it increases human fertility also.

In the final session, Fraser Darling presented a spirited analysis of the ravages man has wrought in most of the areas he has dominated, though he accepted pastoralism as less harmful than other activities so long as it is fully nomadic. In discussion he extended the area best suited to pastoralism to include 'wet deserts' such as Scotland, but did not carry the audience fully with him; several speakers thought that if a little intelligence were used it should be possible to restore fertility to land without letting it revert to scrub for intermittent twenty-year periods. Prof. L. S. Penrose made the basic assumption that an inhomogeneous population probably finds its variety useful, and described various ways in which what at first sign seem to be harmful traits can be of use in a community. He was unconvinced that civilized communities are deteriorating in the manner that eugenists commonly assume, and he argued that, even if there were this deterioration, there is no reason for thinking that it has a genetic rather than an environmental origin. Colourful phrases such as 'humanity is silently rotting at the core' and is being 'recruited from submen' seemed to him without foundation and no one in the audience saw fit to support them. The topical question was raised of the long-term genetical effects of the increase in radiation to which, as a result of industry and nuclear weapon testing, we are being exposed. Penrose thought that the increased mutation-rate that this would probably lead to, simply added one more imponderable to an already ample supply, and would make no positive predictions about its effect.

Lord Boyd Orr, summing up the symposium, said that he welcomed all the developments there might be in sanitation and preventive medicine, on one hand, and contraception on the other. To a large extent they cancel one another out, but he expected the world to hold perhaps 4G ($G = 10^9$) people by 1980 and 5 or 6G by the end of the century. This prospect, and the prospect that the existing ratios between the numbers of the different nationalities would be altered, left him unworried. With modern knowledge, food production could be increased by a larger factor than population is likely to increase by, and there could be enough for all. The difficulties that he foresaw were political rather than scientific. Physics appears to governments to be much more useful than biology both in war and for making money; it therefore gets the lion's share of research endowment. People had got on very well in the past without jet planes and hydrogen bombs, but they could not get on without food, and he looked forward to an era of agrarian abundance in which we no longer galloped through irreplaceable resources with our present abandon but farmed wisely and depended for our energy supplies primarily on the inexhaustible flow from the sun. He looked forward to a magnificent new world even though it is likely to be very different from the one we have known as children. But we would only get it if we got rid of fear and used our wits.

The humanism of Lord Boyd Orr's tone of exuberant confidence suited the mood of the symposium and it finished in an atmosphere of restrained optimism. It did not, however, go so far as to produce overt Swinburnian exaltation: "Glory to Man in the highest! for Man is the master of things".

N. W. Pirie

CHEMICAL RESEARCH LABORATORY, TEDDINGTON

OPEN DAYS

For the eighth year in succession the Chemical Research Laboratory, Teddington, was open to visitors from universities, industry and government departments during September 28–October 1. Exhibits by the High Polymers Group illustrated how systematic changes in the structure of the resin matrix and the number or nature of the functional groups can lead to resins of particular value in specific separations. Resins containing amphoteric groups were shown which act as insoluble sequestering agents with great selectivity for certain ions such as copper. Of special interest were the ion-selective membranes. These are of considerable importance in physical and biological science and are being used in osmometry and dialysis. Polyvinyl alcohol and methoxymethyl nylon films of graded permeability have considerably extended the scope and accuracy of osmotic pressure measurements; other membranes show promise for use in the dialysis of aqueous solutions.

The Radiochemical Group showed a wide range of chromatographic methods of analysis as applied to the inorganic field. A striking example was the simplified and rapid method for field use in geochemical prospecting. Applications of ion-exchange resins were demonstrated: in one, the quantitative separation of metals such as copper, cobalt and nickel adsorbed on an acidic ion-exchanger was effected by an organic solvent; in another, gold and other metals (such as zinc, nickel, copper, iron, silver and cobalt) adsorbed on a strong base exchanger could be eluted separately by use of suitable organic solvents. Other separations involved the use of ion-exchange membranes.

A novel apparatus for continuous extraction of a metal salt solution by organic liquids consisted of a rotating cylinder mounted concentrically inside a stationary outer vessel; the liquids passed counter-current in the annular space between the cylinders. The measurement of carbon-14 based on the use of acetylene in a scintillation counter was demonstrated, the acetylene being prepared from carbon dioxide by reaction with lithium and conversion to carbide. The method is particularly useful for very low activities.

In the Inorganic Group, an exhibit demonstrating the occurrence of selenium in wastes from the flash-roasting of pyrites typified the interest taken by the Laboratory in waste materials as sources of valuable products. Wastes from pyrites plants arise in the final purification of the sulphur dioxide by acid wash or water sprays; samples were shown containing from 20 to 60 per cent of selenium. Methods of recovering the element are being studied and various products were on view, as well as excellent specimens of the various allotropic modifications of selenium. Work has been commenced on the separation of rare earths by ion-exchangers, and promising separations of the cerium group of elements have been made using ethylenediamine tetra-acetic acid as the eluting agent. Techniques for the preparation of pure rare-earth metals are being studied, and samples of cerium and lanthanum by reduction of the fluorides with lithium were shown. The fine collection of metals of high-degree purity held by the Laboratory on behalf of the Pure Metals Committee of the Department of Scientific and Industrial Research was again on view.

The current programme of the Organic Group was illustrated by collections of new intermediates and pure chemicals of potential usefulness. A recently introduced technique, that of zone melting, was shown in its application to the purification of organic compounds. The convenience of this method lies in the ease with which the cycle of operations can be repeated automatically. The purification effected was strikingly demonstrated by the removal of a coloured material, induline, from naphthalene.

Other interesting apparatus included that used for pressing clear disks from mixtures of pure potassium chloride and various solid organic materials for examination by infra-red absorption spectroscopy; a cryoscope for measurements of the vapour pressure of acetylene; and a micro-analytical train in which isotopically labelled carbon dioxide was collected for isotope abundance measurement. Progress in preparative and synthetic work was shown under the following headings: an exploration of possible uses of 4-hydroxy-*iso*phthalic acid and its derivatives; reactions of epoxides with phosgene; isomerization of ethyl*cyclo*pentane; new methods of labelling aromatic compounds; and new ion-exchange resins.

The National Collection of Industrial Bacteria presented a colourful exhibit in which various pigment-producing bacteria were used to produce paintings and the printing of words on agar plates. The more prosaic work of the Collection was illustrated by demonstrations of the techniques employed in identifying, classifying and preserving bacteria.

An apparatus of interest to fermentation technologists was that used for the continuous anaerobic culture of sulphate-reducing bacteria, in which hydrogen is the reducing agent and carbon dioxide the main carbon source. The apparatus, which was developed at the Microbiological Research Department, Porton, for aerobic organisms, can be adapted for the culture of most micro-organisms; the continuous technique is claimed to be more efficient than batch fermentation. A process for the production of sulphide from sulphated sewage sludge was demonstrated. At present the sulphide is produced at the expense of the valuable methane formed during the normal digestion of sludge; attempts are being made to enable the two processes to proceed simultaneously. Chromatographic techniques have been applied to follow the carbon metabolism in sulphate-reducing bacteria, and a new type of cytochrome has been detected in these organisms. This is the first time that a cytochrome has been observed in an anaerobic organism.

The field covered by the Corrosion Group was strikingly demonstrated by a wide variety of exhibits. Of particular interest was a collection of characteristic examples of damage by corrosion in industry and in the home. The common danger of using unsuitable combination of metals in constructions was illustrated by galvanic cells in which various pairs of metals were immersed in salt solution. Specimen tubes and histograms of corrosion data showing the influence of various treatments of tubes and boiler water illustrated the study of the corrosion of mild steel tubes in Scotch marine boilers undertaken on behalf of the British Shipbuilding Research Association. New studies of the oxidation of special steels in flue-gas atmospheres have been commenced in collaboration with the British Electrical and Allied Industries Research Association and the British Iron and Steel Research Association; a new apparatus designed for this work was on view.

Ancient buried iron objects in a good state of preservation illustrated the inhibitive effect of tannins in the soil on the activities of sulphate-reducing bacteria. Field trials of tannins as a means of combating underground corrosion are in progress. Recent work on the prevention of tarnishing of copper and silver has led to the use of paper wraps impregnated with certain compounds, for example, copper chromate. The method is based on the removal of traces of hydrogen sulphide from the air. Other exhibits included the rapid attack of steel by aqueous suspensions of sulphur; the use of *cyclo*hexylamine carbonate as a vapour-phase inhibitor; applications of sodium benzoate and sodium nitrite in cooling systems; and examples of filiform corrosion. A new and comprehensive classification scheme for corrosion topics was on view.

NEWS and VIEWS

Nobel Prize for Physiology and Medicine: Profs. J. F. Enders, F. C. Robbins and T. H. Weller

The Nobel Prize for Physiology and Medicine for 1954 has been awarded jointly to Prof. John F. Enders, of Boston, Prof. Frederick C. Robbins, of Cleveland, and Prof. Thomas H. Weller, of Boston, for their work on poliomyelitis. This team of workers had been studying the growth of certain human viral infections in tissue culture. Early in 1949, they announced that the Lansing strain of poliomyelitis virus caused cytopathogenic changes in cultures of various human embryonic tissues and that this action could be neutralized by specific antibody. Afterwards, their isolation of the three known serological types of poliomyelitis virus in tissue cultures by direct inoculation with fæcal material from human subjects, along with the demonstration of direct typing of the virus strain with specific antisera, has opened up a new field in the laboratory diagnosis of the disease and is providing also a valuable technique for epidemiological studies. The utilization of tissue-culture methods for the possible production of safe poliomyelitis vaccines is another immediate result of immense practical importance and is now being actively pursued.

An additional contribution of all this work is that it has brought poliomyelitis research within the reach of investigators previously debarred by lack of elaborate experimental facilities. Of special importance, however, to virus research is the unequivocal demonstration that an apparently strictly neurotropic virus can multiply *in vitro* in cells which are not ordinarily susceptible to it *in vivo*, and the conditions and mode of growth in such a system have applications for other problems. Within the past year, Prof. Weller has described the cultivation of chicken pox and herpes zoster viruses, and Prof. Enders that of measles virus in tissue culture. The stimulus of all these discoveries is activating research not only in virology but also in microbiology generally.

Presidency of the Royal Aeronautical Society: Mr. N. E. Rowe, C.B.E.

Mr. N. E. Rowe, technical director of Blackburn and General Aircraft, Ltd., Brough, East Yorks, has been selected as president-elect of the Royal Aeronautical Society and will take office at the annual general meeting of the Society to be held on May 5, 1955. After his apprenticeship in marine engineering at Devonport Dockyard and service in the First World War, Mr. Rowe went to the Imperial College of Science and Technology, London, holding a Royal scholarship and Whitworth exhibition, and gained a diploma of the College in 1924 for postgraduate work in hydro-electric engineering. During 1924–46 he was employed by the Air Ministry and the Ministry of Aircraft Production, becoming director of technical development in 1941 and director-general of technical development four years later. From 1946 until the end of 1951, when he took up his present post, Mr. Rowe was controller of research and special developments for British European Airways. He was elected a Fellow of the Royal Aeronautical Society in 1942, and has been a member of council since that year; he is also a member of council of the Helicopter Association. In 1944 he was made C.B.E. for his work in the Ministry of Aircraft Production.

Chemical Engineering in Great Britain

In his presidential address on April 30 to the Institution of Chemical Engineers at the thirty-second annual meeting, Mr. Stanley Robson spoke mainly on the progress of the Institution and the steps it is taking to assist industry by the provision of highly qualified chemical engineers. The full address, which has only recently been made available, includes many interesting figures, among which may be specially mentioned the increase in production of the chemical industry by 29 per cent from 1948 to 1952. In the same period the number of operatives scarcely changed, indicating the greatly improved efficiency per man employed. This is no doubt largely due to the increase of 20 per cent in the number of qualified scientific workers in the industry. Membership of the Institution simultaneously increased by the satisfactory figure of 30 per cent, while training facilities, in which it is keenly interested, are now available in more than twenty colleges as opposed to four in 1934. Comparative tables showing the relative numbers of chemical engineers employed by different industries in Great Britain and in the United States, and also the numbers engaged in various occupations such as plant operation, show, generally speaking, remarkable agreement, the main differences being that 20 per cent held administrative posts in Britain, as opposed to 10 per cent in the United States, and 22 per cent undertook research and development, as against 31 per cent. It follows that statements which have been made that chemical engineers in the two countries have different functions, and that consequently their training should be on different lines, have little to support them. A more important problem is the securing of adequate supplies of men to train, and the Institution, by issuing the publication "Careers in Chemical Engineering", for which there has been a widespread demand, has made a very valuable contribution to this side of the question. As Mr. Robson pointed out, in spite of this and the many other activities of the Institution for encouraging the development of chemical engineering and keeping its members in touch with recent progress, there is no room for complacency. The present trend in the chemical industry is to build much larger and more complicated units of plant; this can only be done after extensive and costly research and by making use of chemical engineers of the first grade, with scientific training of the highest order.

Bulletin of Endemic Diseases

Important developments in preventive medicine in Iraq have prompted the publication, by the Institute of Endemic Diseases, Baghdad, of a new journal, the *Bulletin of Endemic Diseases*, the first issue of which is dated July 1954 (6*s*. per issue; 20*s*. for four issues). The *Bulletin* will be issued approximately every six months and its articles will be in English. Issued with the authority of the Ministry of Health and the Government of Iraq, this new journal is tastefully produced and well printed in Baghdad. Its objects are to publish original papers on the epidemiology of parasitic and insect-borne diseases, especially those relating to Iraq. This first issue contains a detailed summary, by Dr. Gordon Pringle, of the Institute of Endemic Diseases, Baghdad, of existing knowledge of malaria in Iraq before 1946 and of its control; an article, by the same author, on the identification of adult anopheline mosquitoes of Iraq and neighbouring territories; a preliminary study, by Hannah Zakaria, of the Biology Department, Royal College of Medicine, Baghdad, of the bionomics of snails belonging to the genus *Bulinus* in a locality near Baghdad, the inhabitants of which are heavily infected with schistosomiasis; a preliminary report, by Younis Bashir, of the Pathological Laboratory, Royal Hospital, Mosul, on the occurrence of infantile kala-azar in northern Iraq, with an editorial comment on other cases observed in the region of Baghdad and central Iraq and on the survey of sand-flies (Phlebotominae) of infected localities that has been begun; and an account, by Haikal Riyadh and Mohammed Azzawi, of the Institute of Endemic Diseases, Baghdad, of a comparison of the efficiency of two types of sprayer used for malaria control with DDT. Everyone interested in the progress of knowledge of tropical medicine will welcome this addition to the literature of this subject and will wish every success to its editorial board and to the workers whose results will appear in this new *Bulletin*. The Institute of Endemic Diseases is establishing a library, and its secretary appeals for exchanges of journals on tropical medicine and hygiene, medical zoology and parasitology, microbiology, hydrobiology and related sciences.

Histochemische Methoden

A useful new publication entitled *Histochemische Methoden* has appeared under the editorship of Dr. Walter Lipp, of Graz, Austria. It consists of concise working directions for carrying out the selective staining of tissues for the detection and location of specific inorganic and organic substances, chemical groupings and enzymes. General histochemical procedures such as preparation of tissues will also be covered. A short bibliography is provided with each method. The three issues which so far have appeared have included among other topics the detection of potassium, arginine, carbohydrates (polysaccharides), sulphydryl and disulphide groups, and esterases. The publisher is R. Oldenbourg, of Munich, and the price is 30 DM. a year (six parts) or 6 DM. for separate parts.

Forest Products Research: Report for 1953

The report for 1953 of the Forest Products Research Board, together with the report of the Director of Forest Products Research (pp. vi+62+8 plates. London: H.M. Stationery Office, 1954. 3*s*. net), opens with the statement that the major work of the year has continued to be the evaluation of new tropical species of likely importance, while there has been an increasing amount of testing and assessment of sample consignments of home-grown species from the plantations of the Forestry Commission. The former work is undertaken with the object of finding new timbers from the tropical forest likely to be of importance to manufacturers and timber users. This latter research is of first-class importance to the tropical sylviculturist, for such knowledge will assist him in the future management of tropical crops in which formerly only one or two species had any marketable timber value. Kiln-drying experiments are still being undertaken, especially in connexion with the hardwoods, where favourable results are being obtained. Satisfactory factors are coming to light in connexion with wood bonding and the weathering of plywood investigations. In this latter, weathering tests have been carried out both in Britain and in Nigeria over the past three years. The principal object of the tests was to assess the durability of the glues used in the manufacture of plywood. In the entomology branch, studies of the common furniture beetle and the house longicorn beetle, the latter a serious pest on the Continent of Europe but in Great Britain chiefly confined to Surrey, have been given priority because of their importance.

Similarity of Algal Proteins

The gross chemical composition of many algae has now been recorded. In a recent paper, W. Fowden (*Ann. Bot.*, N.S., 18, 71, 258; 1954) describes how he has isolated representative protein fractions from species from four different systematic classes, namely, *Chlorella*, *Anabaena*, *Navicula* and *Tribonema*, and made quantitative determinations of their amino-acid compositions. This important investigation has shown that there is a close similarity in the proteins of the four species selected for study, and hence the tentative conclusion is reached that the protein complements of all algae are similar. It will be recalled that the contemporary accepted classification of the algae is based on the composition of their pigments and storage materials. The author points out that his analytical methods only provide an average amino-acid composition of the bulk protein of each species and can give no information regarding the nature and reaction of the individual proteins which may be present. He has also indicated that there is a general similarity between the bulk proteins of algae and those of the leaves and tubers of some flowering plants and of *Nitrosomonas*; but, as with the algae, these materials probably contain different individual proteins, these determining the characteristic metabolism of the species.

Root Culture and Biochemical Genetics

The technique of excised root culture affords a means of investigating the hormonal control of plant growth and seems likely also to prove of value in biochemical–genetical studies of the tissues of higher plants. W. G. Boll (*New Phytol.*, 53, 2, 177; 1954) has discussed the problems involved in the application of the technique of root culture to comparisons between strains and hybrids of the tomato. The growth of six clones of excised roots, each derived from a different seed of one inbred plant of an inbred line of tomato, was studied through a series of passages. Both quantitative and qualitative differences were found between the clones. The implications of the results are discussed. Using a seven-day passage and a modified White's medium it was found that root apices, of the strains and hybrids of tomato used, only occasionally survived on subculture into a second passage. Experiments designed to overcome this difficulty are described. Reduction of the passage length, or control of pH drift, increased the expectation of life of the apices on subculture; but conditions permitting continuous subculture of the radical apex were not realized. The implications of these results, and of the effects of the different media on the growth of excised tomato roots, are discussed.

University of Birmingham

Dr. C. A. Rogers, formerly reader in the Department of Pure Mathematics, University College, London, has been appointed to the Mason chair of pure mathematics in the University of Birmingham. The following appointments have been announced by the University: Dr. J. D. Lawson, lecturer in geology; Dr. J. N. Pratt, lecturer in physical metallurgy; M. G. Cockcroft, lecturer in industrial metallurgy; F. Benson, lecturer in engineering production; Dr. A. Kelly, Imperial Chemical Industries, Ltd., Fellow in industrial metallurgy. Dr. S. R. Carter, lecturer in chemistry in the University, has recently retired. The following have resigned their posts: Dr. C. S. Ball, lecturer in industrial metallurgy; Dr. J. H. Cort, lecturer in physiology; Mrs. B. Eckstein, lecturer in geography; H. Grisbrook, lecturer in engineering production; Dr. H. Nuttall, lecturer in mechanical engineering; E. C. Park, research Fellow in physics; Dr. C. A. Ramm, lecturer in physics; G. K. Williamson, Imperial Chemical Industries, Ltd., research Fellow in physics; J. Y. Freeman, Department of Scientific and Industrial Research research assistant in physics; R. F. Coe, Department of Scientific and Industrial Research research Fellow in physics.

Bishop Museum, Honolulu, Hawaii

The annual report of the Bishop Museum for 1953 recalls that the Bernice P. Bishop Museum was founded in 1889 with a sphere of interest described as "Polynesian and kindred antiquities, ethnography and natural history". The Museum made its reputation through its sponsorship of field research in the natural history and anthropology of the Pacific area and through publication of the results of such research. But those concerned with the Museum realized that their educational role lay in the diffusion of knowledge. Although the Bishop Museum had maintained exhibition halls, it had no policy in this direction, and one of the present major objectives is to transform the Museum into an effective instrument of education through informative and dramatic display techniques in the galleries.

University of Sheffield

The following appointments have been made in the University of Sheffield: Dr. A. Roberts, senior lecturer in the Postgraduate School of Mining; P. B. N. Neal and D. M. Woo, lecturers in mechanical engineering; and P. H. Mann, lecturer in social studies. The following have resigned their posts in the University: Dr. H. E. Harding, reader in pathology, on appointment as director of pathology to the Salisbury Area Pathological Service; Dr. R. Shepherd, senior lecturer in the Postgraduate School of Mining, on appointment as a senior scientist with the National Coal Board; Dr. C. E. Davies, senior lecturer in medicine, on appointment as consultant physician to the United Sheffield Hospitals; B. R. Dudley, lecturer in applied mathematics; Miss C. M. Hamill, lecturer in pure mathematics; and F. G. West-Oram, lecturer in glass technology. Mr. P. Irwin Packington has given a cabin cruiser to the Department of Zoology for use in both coastal and inland waters.

Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: J. Bowden (entomologist, Gold Coast), senior specialist, Department of Agriculture, Gold Coast; T. W. Brandon (government chemist, Public Works Department, Gold Coast), specialist, water examination, Public Works Department, Gold Coast; N. O. Walsh (senior scientific officer, Jamaica), deputy government chemist, Jamaica; H. M. Maugham-Brown (assistant conservator of forests, Tanganyika), conservator of forests, Tanganyika; T. P. Lecky (senior livestock officer, Jamaica), chief livestock officer, Jamaica; C. S. Ramage (scientific officer, Royal Observatory, Hong Kong), assistant director, Royal Observatory, Hong Kong; R. H. Bennison and B. F. Hanger, agricultural officers, Kenya; B. Buckler, agricultural officer, Zanzibar; D. L. Curtis, plant breeder, Nigeria; J. W. Deering, agricultural officer, Fiji; G. Dowson, agricultural officer, Sarawak; M. J. Furber and A. B. Hearn, agricultural officers, Nyasaland; R. C. Knill, agricultural officer, Sierra Leone; W. P. Mowat, plant pathologist, Tanganyika; A. J. Pritchard, botanist, Uganda; J. J. Rae, agricultural officer, Nigeria; E. M. Laing, field geologist, Sierra Leone; G. P. Jones, geologist, Nigeria; A. R. Newton, geologist, Northern Rhodesia; W. J. Phillips, geologist, Uganda; R. D. Brown, veterinary research officer (virologist), East Africa High Commission; T. E. Fletcher, scientific officer (chemist), East African Malaria Unit; M. C. Williams, medical research officer, grade 3, East Africa High Commission; J. Williamson, research parasitologist, West African Institute for Trypanosomiasis Research, Nigeria; J. R. Lang-Brown, assistant conservator of forests, Uganda; M. J. Davies, assistant conservator of forests, Nigeria; S. R. M. Harvey, geologist, Fiji; Miss E. M. Holden, biochemist, West African Cacao Research Institute, Gold Coast; J. E. McKerlie, assistant conservator of forests, Tanganyika; E. B. May, agronomist, West African Institute for Oil Palm Research, Nigeria; J. C. Parkinson, assistant conservator of forests, Fiji.

The Night Sky in November

FULL moon occurs on Nov. 10d. 14h. 29m., U.T., and new moon on Nov. 25d. 12h. 30m. The following conjunctions with the moon take place: Nov. 3d. 19h., Mars 5° S.; Nov. 15d. 14h., Jupiter 2° N.; Nov. 24d. 03h., Saturn 6° N.; Nov. 24d. 03h., Mercury 6° N.; Nov. 24d. 07h., Venus 2° N. In addition to these conjunctions with the moon, Mercury is in conjunction with Saturn on Nov. 24d. 01h., Mercury 0·4° S., and also in conjunction with Venus on Nov. 25d. 05h., Mercury 3° N.; and Venus is in conjunction with Saturn on Nov. 29d. 00h., Venus 2·5° S. Mercury is a morning star and rises nearly two hours before the sun on November 15, when it is visible, but throughout most of the month it is too close to the sun for observation. Venus is unfavourably placed for observation during most of the month and is in inferior conjunction on November 15. At the end of the month it rises about two hours before the sun and can be seen in the eastern sky, stellar magnitude −4. Mars, an evening star, sets at about 22h. 10m. during the month. Its stellar magnitude varies between 0·1 and 0·5, the decrease in brightness being due to its increasing distance from the earth—from 91 to 111 million miles. It moves from Capricornus into Aquarius, and on November 10 it lies almost south of and close to θ Capricorni. Jupiter rises at 21h. 35m., 20h. 45m. and 19h. 40m. on November 1, 15 and 30, respectively; owing to its decrease in distance from the earth by about 38 million miles, its stellar magnitude changes from −1·8 to −2 during the month. Saturn, in conjunction with the sun on November 5, is unobservable in the early part of the month; on November 15 it rises less than an hour before the sun but by the end of the month it rises at 5h. 30m., more than two hours before sunrise, and can be seen a little north-east of α Librae. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Nov. 5d. 23h. 55·7m., χ Aquar. (*D*); Nov. 6d. 22h. 27·7m., χ Pisc. (*D*); Nov. 12d. 23h. 38·6m., 121 Taur. (*R*); Nov. 14d. 05h. 52·3m., *d* Gemi. (*R*); Nov. 20d. 03h. 45·9m., 13*B* Virg. (*R*). (*D*) and (*R*) refer to disappearance and reappearance, respectively. The Andromedid meteors, associated with Biela's Comet, attain their maximum about November 28.

Announcements

DR. D. A. ALLAN, director of the Royal Scottish Museum, Edinburgh, has been elected president of the Royal Scottish Geographical Society.

THE title of reader in computational methods in the University of London has been conferred on Dr. A. D. Booth, in respect of his post at Birkbeck College.

As part of the United States conditional aid programme, the Ministry of Agriculture of Northern Ireland has awarded three postgraduate scholarships, each £600 a year, for a period up to two years, as follows: two scholarships in agricultural economics (farm management) to G. L. Morrison (University of Reading) and W. Thompson (University of Leeds); one scholarship in agricultural statistics to A. A. Rutherford (University of Aberdeen).

THE Fulmer Research Institute, Stoke Poges, Bucks, is arranging an open day, which will be held on November 2.

THE work of the London Group Laboratories of the British Iron and Steel Research Association will be open for inspection at 140 Battersea Park Road, London, S.W.11, on November 18 and 19.

IN conjunction with the annual congress of the British Institute of Radiology, an exhibition of X-ray apparatus will be held at the Royal Horticultural Hall, Vincent Square, Westminster, London, S.W.1, during November 23–26 (Nov. 23, 2 p.m.–6 p.m.; Nov. 24 and 26, 9 a.m.–6 p.m.; Nov. 25, 9 a.m.–8 p.m.). Admission tickets, which are free, can be obtained from the British Institute of Radiology, 32 Welbeck Street, London, W.1.

THE Northern Branch of Aslib will hold a one-day conference on November 19 in the North of England Mining and Mechanical Institute, Neville Hall, Newcastle upon Tyne, with Mr. R. W. Mann, managing director of Victor Products, Ltd., Wallsend upon Tyne, in the chair. Four papers will be read dealing respectively with the activities of Aslib; public technical library service for industry; microfilming; and new ideas and the small firm. The conference will be open to non-members on completion of a registration form (to be returned by November 12) which is obtainable from the honorary organizing secretary, Mr. E. Westerby, 11 Duchess Street, Whitley Bay, Northumberland.

THE MURDOCH BICENTENARY

THIS year marks the bicentenary of the birth of William Murdoch (1754–1839), the originator of gas lighting. For that great achievement alone he would stand out as a great figure in the history of progress, yet it was only one of his many inventions. The story of his life should serve as an incentive and example to every scientific worker. Possibly forgotten is the incident of the wooden hat which brought about his association with Matthew Boulton and James Watt, and his opportunity for achievement. After having walked all the way from his home in Ayrshire to the now famous Soho Works in Birmingham, he might have been turned away by Boulton had not Murdoch dropped his wooden hat at the prospective employer's rebuff. Boulton noticed, however, the unusual character of his head-gear, questioned him about it, and learnt that he was the inventor of the oval lathe with which he had made it. That was the beginning of the famous triple partnership.

As a boy, Murdoch had made himself 'a wooden horse' for his journeys to school, a distance of 2½ miles; it was the forerunner of the tricycle and the bicycle, which only became a practical reality many years later. This experience ultimately led him to construct a model non-condensing locomotive steam-engine, now in the Birmingham Art Gallery; but his attempts to patent it were, strangely enough, opposed by Watt. An entrancing story of these early beginnings and his many other remarkable inventions has been recently published in *West's Gas*, the house journal of West's Social Society, from the pen of his great-grand-niece, Margaret L. Murdoch. Attractive, too, is the 1954 Murdoch Memorial Lecture of the Institution of Gas Engineers, under the distinguished authorship of no less a person than the chairman of Imperial Chemical Industries, Ltd., Dr. Alexander Fleck. Therein has been paid a fitting tribute to Murdoch's memory in a very informative account of the origins and development of gas for industrial purposes, viewed from the angle of an organization which has, above all others, so successfully applied the service of gas to the chemical industry. It is, in Dr. Fleck's words, a record "of the development of a great concert of industrial processes—today as powerful and as full of promise as ever before to make available the things we value in our way of living".

In effect, gas becomes increasingly a great source of chemicals. The vast output of ammonia and nitric acid for chemical manufacture and explosives are the products of a synthesis which begins with the gasification of coke, and the production of hydrogen and carbon monoxide, as water gas. The same process is the starting point of that remarkable synthesis of hydrocarbons and the complex series of by-products associated with the Fischer–Tropsch process, so actively applied to the German economy in the Second World War. From the same origins, with benzene, is produced nylon. From the hydrogenolysis of natural oils and fats arise higher alcohols, solvents and plasticizers, to mention but a limited range of many wonders.

To turn to the wider needs of the fuel industries, there must ultimately come an urgent and crying demand for the greater application of total gasification in the gas and heavy industries, for the supplies of good coking coals are showing signs of exhaustion, and processes must be devised to utilize weakly and non-caking coals. The 'smog' problem also points out the same objective. With the provision of cheap gas for industry, the efficiency and adaptability of many types of heating and processing plant become greatly advanced. A process for the cheap production of oxygen would expedite all the prospective developments in this field. That the gasification of oil may also serve as a useful adjunct to the processes based on coal may be envisaged with a measure of certainty. In the pursuit of these objectives, reference to the example of Murdoch's career may be timely—to the example of his energy and persistence in an age when technical skills were weak and groping, under rebuffs and disappointments such as the opposition of no less a person than Watt. But for this opposition, Murdoch's locomotive would have been an accomplished fact nearly half a century before Stephenson's, and a quarter of a century before Trevethick's. Indeed, as a boy, Trevethick had been a frequent visitor to Murdoch's home at Redruth, and must have seen him at work on his engine. It is said that Trevethick purchased the model from the disappointed inventor. Murdoch has been called "the incomparable mechanic"; further, we must recognize what an amazing achievement has emerged from disappointment and effort.

R. J. SARJANT

THE HEALTH OF CHILDREN

A NEW exhibition at the Wellcome Historical Medical Museum, at 28 Portman Square, London, W.1, deals with "The Child Through the Ages" and illustrates by means of skilfully selected objects, books and prints the methods which have been used to feed, clothe and transport the young child from early times. It also shows the development of the idea that disease in the child is often so different from that in the adult as to warrant the creation of the specialty later termed 'pædiatrics'. This exhibition covers the whole field from the earliest times to the beginning of the present century. It contains many objects of great beauty, and is worthy of the traditions of the Wellcome Museum.

It is well known that the Museum possesses a very fine collection of effigies of ancient Egyptian gods, and a few of these are shown in this exhibition. In the classical period of Greece and Rome the emphasis is rather on the portrayal of the mother with her child. Third-dimensional art had become fully representational, and the artists found in this theme a congenial subject. Some of these third-century B.C. terra cottas show a gracefulness of line which often escapes more ambitious compositions. The marble bas-relief from Ostia of a mother suckling her child exhibits a different treatment from that used in the Greek figures, and is also noteworthy.

During the medieval period, the attitude of the Christian Church resulted in the cult of certain saints who were especially concerned with the care of children. This attitude is exemplified by several very interesting Breton effigies in wood, dating from the thirteenth century and later. The Renaissance saw the foundation of the Ospedale degli Innocenti at Florence, with its well-known Della Robbia medallions, and there are exhibited a number of interesting illustrations of this and similar institutions.

So far as the management and treatment of children were concerned, there was little change in practice from the time of Soranus (first century A.D.) until the seventeenth century. During the sixteenth century the popular emphasis was on swaddling clothes, the bath and the baby's toilet. Prints by the Dutch, French and Italian masters depict such scenes, and sometimes show practices which are not referred to in the books of the period. The humanitarian movement in Great Britain, so well epitomized by Thomas Coram with his establishment of the Foundling Hospital, led finally to George Armstrong's dispensary (1769) and to the foundation of hospitals for sick children. The Industrial Revolution and the consequent employment of children in industry led to results which are illustrated by contemporary documents. The work of the great Victorian sanitary reformers had an important bearing on the welfare of children. But it was towards the close of the nineteenth century that French work on infant feeding was taken up in Britain and led directly to the great infant welfare movement.

The development of pædiatrics as a specialty is well illustrated in this exhibition by the first editions of many of the classics of that subject, such as the books by Hieronymus Mercurialis, Thomas Phaer, Robert Pemell and Walter Harris, to name only a few of those which are shown.

Some comments may be made regarding methods of feeding infants at different periods. Some of the third-century B.C. Greek feeding bottles which are shown have artistic merit. The Roman feeding vessels are of a glass of great beauty. One of the most interesting types of feeding vessels exhibited is the so-called breast-shaped feeding bottle, used by the Greek settlers in southern Italy during the three centuries before our era, of which several examples are shown. Of a complicated design, these charming bottles must have been difficult to fill and next to impossible to keep clean. In the sixteenth and seventeenth centuries feeding bottles resembled rather large spice pots, and were made in pewter. Several fine examples are shown. The early nineteenth century saw the florescence of the boat-shaped feeding bottle, with a spout at one end and an opening for filling on the upper side. Made at first in porcelain and earthenware, some had interesting designs. Wedgwood and Spode both made such types. From these to similar glass vessels was a short step. Some fine cradles of different periods are also shown, together with the 'walking-stool' which appears in paintings by the great masters as early as the sixteenth century.

As a pendant to the historical exposition, some cases are devoted to the management of the child among primitive races. The baby-carriers used by certain African tribes and by the American Indians are beautifully made. Those of the Indians consist of highly decorated pouches of hide. The feeding of infants among primitive peoples is illustrated by several carvings. One of the most interesting of these is a fine ivory from Central Africa, showing a mother suckling her child. The exhibition also contains a very interesting series of amulets, used both by primitive peoples and by Europeans up to the present day.

EAST AFRICA HIGH COMMISSION

REPORT FOR 1953

THE East Africa High Commission was constituted on December 19, 1947, to replace the East African Governors' Conference, and came into operation on January 1, 1948. It grew out of the experience of common administrative organization of the Second World War, and the scope of the Commission is due for review before the end of 1955. Its purview included on January 1, 1948, the four research organizations comprised in the East African Research Services, to which have since been added the Desert Locust Survey and Control, the East African Bureau of Research in Medicine and Hygiene, the Filariasis Research Unit, the East African Medical Survey, the Virus Research Unit, the East African Malaria Unit, the East African Inter-Territorial Leprosy Specialist and the East African Marine Fisheries Research Organization. Although the annual report of the Commission for 1953* includes as Part 3 an account of the evolution and of the constitution and scope of the Commission, out of its total of ninety-eight pages a full forty are concerned with the research and scientific services, and the record of activities thus presented is one which is of unusual interest to the scientist, whose clearly evinced support may be required if next year is to see no interruption to such services and the provision of inter-territorial financial support on an adequate scale.

During the year the East African Advisory Council on Agriculture, Animal Industry and Forestry was replaced by a Governing Body for the Natural Resources Group of the High Commission Research Services. The Body now constituted will be responsible for seeing that the activities of the four East African Research Organizations are directed to effective ends and supervising their general financial policy. To some extent the chapter of the report dealing with research and scientific services overlaps with that in "Colonial Research", but fuller accounts are given of certain activities than is possible in that report. On the other hand, the activities of the East African Industrial Research Board are covered more fully in the eleventh annual report of that Board (see *Nature*, September 4, p. 430). In the East African Agriculture and Forestry Research Organization, completion of farm buildings for the Animal Industry Division filled a main gap in research facilities, and the Plant Quarantine Station at Muguga was also completed during the year. Considerable work was carried out on breeding crop plants for resistance to disease, particular success being had with a strain of maize resistant to rust (*Puccinia polysora*). Entomological research was directed mainly towards the survey of insects attacking forest trees and timber and investigations of the more dangerous pests and the use of insecticides on field crops. Soils research was concentrated on the characteristics of a soil, determinable by analysis, that will indicate the ability of plants grown on it to respond to dressings of phosphate and nitrogen. The Veterinary Research Organization continued to work on the development of a quantitative serological test for the virus and antibodies of rinderpest, as well as field surveys of east coast fever, studies on problems of identification of the genera

Rhipicephalus and *Hyalomma* and on paramphistomes of domestic ruminants and on the larvæ of *Haemonchus contortus*.

Good progress was made with the construction of the Central Trypanosomiasis Research Laboratory at Sukulu, Uganda, and fields-trials to determine the role of biting-flies in the spread of animal trypanosomiasis in tsetse-free country were continued, while treatment with 'Antrycide' pro-salt at two-monthly intervals for a limited period protected cattle exposed daily to attacks of the tsetse *Glossina austeni* even after cessation of treatment. Research on the race of *G. morsitans*, which occupies about a hundred thousand square miles of the western fly-belt of Tanganyika, was extended to include the race of *G. morsitans* inhabiting a different type of vegetation in some ninety thousand square miles of eastern and southern Tanganyika. Important advances in the determination of blood meals taken up by tsetse flies have been made and were due to be published.

A comprehensive collection of hydrological data from Lake Victoria by the Fisheries Research Organization indicated a significant lack of sulphates in the waters of Lake Victoria, and the complicated water movements in this lake have to some extent been related to the variable growth of plankton in different areas. Data on the growth-rate of *Tilapia* indicate that the quality of the food may be more important than the amount. Some successful fish-marking experiments were carried out in the Kavirondo Gulf, while in marine waters the Marine Fisheries Research Organization made extensive studies on pelagic fish as well as correlated investigations on the plankton or biological content and the hydrography of the area. Good progress was made on the construction of a new headquarters building for the Meteorological Department, which was occupied mainly with providing a forecast service covering East Africa and an area of the Indian Ocean and with the collection and collation of climatological records.

At the end of 1953 the total strength of the Desert Locust Control and Survey was 174 officers and 522 vehicles and, besides the major operations in the Somali Peninsula and in Kenya against the increasing extent and intensity of the plague of the desert locust, fifty swarms of which invaded British East Africa early in 1954, control measures were carried out in Aden, Yemen, Kuwait and Oman. About £1 million was expended on control and research during the year. The Filariasis Research Unit began to operate on July 1, 1949, and the report gives a brief general review of the results achieved by the Unit in its study of bancroftiasis and onchocerciasis methods of control. The reduction of staff in the early stages has necessitated an extension of the scheme before the work in East Africa can be completed. The first phase of the East African Medical Survey also terminated in December 1953. In the five years work reviewed in this report, the surveys conducted in Kenya and Tanganyika have yielded statistical data which illustrate the relation of such influences as agriculture, animal husbandry and domestic practices to the health of the community.

Early in 1953 the Virus Research Institute undertook an investigation which has elucidated the nature of dengue-like fever around Newala in south Tanganyika. Work on yellow fever was less extensive, but a survey was made at Newala; and the Institute is also studying the inter-relation between a virus and its insect host, using rift valley fever and *Aedes aegypti*, and the relation between virus and the host's tissue, using influenza virus and the embryonated hen's egg. Although the activities of the Malaria Unit were restricted by absence of staff, an investigation of the epidemiology of malaria in Buganda was initiated, and one on residual house spraying with 'Gammexane' in the Northern Province of Tanganyika, which was concluded, indicated the uncertainty of house-spraying over a limited area as an anti-malarial measure. Use of mass house-spraying technique indicated that the total anopheline population in an area was about 40 per acre.

The Inter-Territorial Leprologist estimates that £200,000 a year over ten years would be required to attack leprosy on a broad front in all the Territories simultaneously, with good prospect of reducing it to negligible proportions in that period; there are at present some 216,000 leprosy cases, with eighteen leprosaria and various out-patient and rural schemes. Good results are being obtained with sulphone and other specific drugs, and under the regional leprosy surveys of the Territorial Leprologist, rural leprosy work developed particularly well in Uganda.

INTERNATIONAL CONFERENCE ON ELECTRON MICROSCOPY

LONDON, 1954

DURING September 1950 an international conference on electron microscopy was held in Paris, and at an informal meeting of members of the various national groups it was decided that some international organization should be set up to arrange international conferences at regular intervals. The British Group, namely, the Electron Microscopy Group of the Institute of Physics, was asked to investigate the best method of attaining this object. Mr. F. W. Cuckow, who was secretary of the British Group at the time, approached the International Council of Scientific Unions, and it was eventually decided to set up a Joint Commission on Electron Microscopy on which the scientific unions interested in the subject would have representatives. It was the privilege of the Committee of the British Electron Microscopy Group, together with those members of the Joint Commission who could attend committee meetings in London, to organize the first International Conference under the auspices of the Joint Commission, at the London School of Hygiene and Tropical Medicine, during July 15–21. The detailed organization was carried out jointly by Mr. F. W. Cuckow (acting as secretary of the Joint Commission) and Dr. C. E. Challice (as secretary of the British Group). Office facilities were made available by the Institute of Physics. A programme committee, consisting largely of the secretaries of the national groups, was set up, with Dr. V. E. Cosslett (chairman, British Group) as its secretary. At the beginning of the conference the Joint Commission held its first meeting and before the conclusion of the conference a committee had been set up, under the Commission to co-ordinate future international meetings.

After the Conference had been formally opened, three invited survey papers were read. First, Prof. B. von Borries (Technische Hochschule, Aachen), a pioneer in the electron microscope field, reviewed recent developments in the use of beams of fast-moving corpuscles for microscopy. Dr. F. S. Sjöstrand (Karolinska Institut, Stockholm) outlined recent advances in biological knowledge achieved with the electron microscope, and devoted most of his review to the outstanding results obtained in the past two years by the application of the ultra-thin sectioning technique, of which he himself was a pioneer. Dr. J. Nutting (Metallurgy Laboratory, Cambridge) then surveyed the developments in metallurgical, chemical and industrial applications of the instrument.

Following these three papers came the sessions of original contributions. It would be impossible to present, in the space available, even an indicative review of the 160 papers read, as the result would be merely a list of titles. In any event, in order to get through this number of papers in the five working days assigned to the meeting, parallel sessions had to be held on four of the afternoons and one morning, thus making it impossible for anyone to hear all the papers read. As the authors' abstracts are available[1] and the full proceedings are to be published[2], the scientific sessions will be reviewed here in a superficial manner only.

Electron Optics

Seven sessions were devoted to subjects which can be classified under this general heading. Two theoretical sessions, one on electron optical theory (twelve papers) and one on electron interference and phase effects (three papers), showed that more consideration is now being given to aberration theory than to general lens theory. Some interesting practical results from a 'phase-contrast' electron optical system were produced by M. Marcel Locquin (Paris). A more experimental session on ion microscopes and X-ray microscopes (six papers) included papers on a lithium ion microscope (Dr. M. Gauzit, Paris) and a proton microscope (Prof. G. Magnan and Dr. P. Chanson, Paris) together with three papers on the theory and application of the X-ray shadow microscope. Dr. R. Castaing (Toulouse) gave a summary of his work on electron probe techniques. A session on emission and reflexion microscopy (six papers) included a report from Prof. G. Dupouy and Prof. Ch. Fert (Toulouse) on reflexion electron microscopes and a description of metallurgical emission-microscopical techniques by members of the Philips Co.'s research team. Spectacular results obtained by Prof. G. Mollenstedt and Dr. M. Keller (Mosbach-Baden) were shown. Their apparatus consisted of an emission microscope in which the cathode (specimen) emission was excited by ion bombardment. Other aspects of emission microscopy were presented in three further contributions.

Three sessions devoted to the conventional type of electron microscope were all intended to be of general interest to users of the instrument. "New Electron Microscopes" (four papers) contained descriptions of two experimental instruments and two commercial models (R.C.A. and Siemens), and "Apparatus; Operation of Microscopes" (nine papers) contained descriptions of a number of pieces of experimental apparatus directly connected with the electron microscope or its use. "The Attainment of High Resolution" (three papers) provided a promise of 5 A. or so resolving powers in the foreseeable future.

Specimen Techniques

Four sessions were devoted to specimen preparation techniques. In that on general specimen techniques (eleven papers) Dr. Marcel Locquin (Paris) described how living specimens contained in a small water-containing cell can be examined in the electron microscope. A number of replica processes for different particular types of specimen were described by other workers, particularly striking results being obtained by Mr. D. E. Bradley (Aldermaston) by the use of carbon replicas. In the session on metallurgical specimens techniques (six papers) a number of methods of preparing metals and metal surfaces for examination by electron microscopy were discussed. The microtomy session contained descriptions of two new microtomes, together with a method of preparing steel knives for cutting ultra-thin sections. A symposium on the preservation of biological material contained five papers. This included two major American contributions, one by Dr. G. E. Palade (New York), whose introduction of the practice of buffering osmic acid for the fixation of tissue has been copied by practically all workers in the field, and the other by Prof. T. F. Anderson (Pennsylvania) on the preservation of structure in dried specimens. The results of Prof. Anderson's technique of taking the medium in which the specimen is suspended around its critical point were presented in a number of most impressive stereo slides.

Non-Biological Applications

The three sessions falling under this general heading showed that considerable progress has been made in this field of application since the 1950 conference. On metallurgical applications there were thirteen contributions in which it was described how the techniques of emission and reflexion microscopy have enabled a number of problems to be studied directly, without the use of replicas, while the carbon replica process has enabled the full resolving power of the conventional transmission electron microscope to be exploited. Studies on steels subjected to various treatments, together with studies on a number of non-ferrous metals, were described. Industrial, chemical and other applications (thirteen papers) referred to all non-biological work not covered by metallurgy, and included some studies on crystals, colloids, rubber, paper and gels.

A symposium on the action of the electron beam on the specimen (five papers) was concerned with the changes both morphological and chemical which take place in the specimen when the electron beam is applied.

Biological Applications

Fifty-seven papers were presented in the sessions on biological applications, and the diversity of the biological fields covered was so great that it is quite impossible to do justice in this review to the work described. Generally speaking, the contributions were dominated by the application of the thin-sectioning techniques which, at the Paris Conference in 1950, were still in their infancy. Bacteria, viruses, spermatozoa and cilia have all been sectioned and examined, together with a large number of tissue cells. Among the virus studies described (fourteen papers) were animal, plant, insect and bacterial viruses, and the bacterial studies (ten papers) covered work performed on a number of different strains of organisms. Internal structure of cells (thirteen papers) included studies on muscle, pancreas, retina, nerve cells and yeasts. Five papers were devoted to the structure of cell and body walls, while eight papers on fibrillar structures included some interesting work on the application of the reflexion technique to the examination of fibres. Work on muscle and collagen was also described. A symposium on the microanatomy of cilia, flagella, etc., included some interesting speculations by Miss W. van Iterson (Amsterdam) on possible relationships between flagella, cilia and sperm tails.

It was interesting to note, throughout the conference, the increasing use which is being made of the stereo technique. This technique is proving of real value, as it is impossible in many specimens to obtain adequate information on spatial relationships by any other method.

In connexion with the Conference, an exhibition of commercial apparatus and books, and also of research micrographs, was held at the London School of Hygiene and Tropical Medicine; indeed, the Conference owed much of its success to the dean and staff of the School for their generous help and for making available excellent facilities.

C. E. Challice

THYROID FUNCTION

As part of a joint meeting with the Association of Clinical Pathologists held at the Grand Hotel, Brighton, on October 2, the afternoon session was devoted to a programme of papers on thyroid function organized by the Association of Clinical Biochemists.

The subject was introduced by Prof. E. J. Wayne (University of Glasgow), who discussed the use of radioiodide in the diagnosis of thyroid disorders. The opinion was expressed that it is preferable to use two or three tests, especially the determination of the thyroid uptake of radioiodine, four hours after a dose, and the plasma protein-bound activity forty-eight hours after a dose. The latter corresponds best with the final clinical diagnosis in cases of hyperthyroidism, while tests based on urinary excretion are specially valuable in the diagnosis of hypothyroid states.

The results of some five hundred cases in which the iodine-131 thigh-neck clearance test was employed were reviewed by Dr. B. W. Meade and Prof. N. F. Maclagan (Westminster Medical School, London). In only forty cases was there a discrepancy between the results of the test and the clinical condition. In seventeen cases which showed a high clearance-rate, sixteen were due to goitrogen administration and one to a large non-toxic goitre. The remaining anomalous results were low—eleven were due to iodide and six to thyroxine; two were post-thyroidectomy, and four were not explained.

Drs. F. Brown and H. Jackson (Christie Hospital, Manchester) then reported the results of the treatment of thyroid carcinomata with therapeutic doses of iodine-131. The plasma was found to contain thyroid protein in addition to thyroxine, and in some cases small amounts of diiodotyrosine. The results of certain animal experiments which were also reported showed that the metabolism of thyroid protein shows a definite species specificity: dog thyroid protein is not metabolized by rats, nor is that from rats metabolized by dogs.

Dr. A. Tickner (Guy's Hospital Medical School, London) discussed the serum cholinesterase level in thyroid disease. It was found to be high in thyrotoxic states and low in myxœdema, but there was some overlap. Since the liver is regarded as the source of cholinesterase, it seems that in thyrotoxicosis the cholinesterase activity is a measure of liver function.

The measurement of thyroid-stimulating hormone in thyroid disorders was reported by Dr. I. C. Gilliland (Postgraduate Medical School, London), who found that the level is high in myxœdema and low in Simmond's disease, whereas in thyrotoxicosis it is low unless eye signs are present, when it is raised. In cases of exophthalmos without thyroid involvement, there is no increase in the thyroid-stimulating hormone-level. Dr. Gilliland therefore concludes that more than one factor is involved.

Drs. A. L. Tárnoky and P. White (Royal Berkshire Hospital and University of Reading) have investigated the relationship between a number of conventional tests in thyroid disease. Highly significant correlations were found between the basal metabolic rate, the serum cholesterol and the urinary pigment: creatinine ratio.

The last paper was by Mr. C. H. Bowden, Prof. N. F. Maclagan and Dr. J. H. Wilkinson (Westminster Medical School, London), who described the application of the ceric sulphate – arsenious acid reaction to the detection of thyroxine and triiodothyronine in plasma. An outline of the techniques employed for the extraction of the protein-bound iodine components from normal plasma and their detection on paper chromatograms was given. Preliminary results indicate that thyroxine and triiodothyronine are components of both normal and thyrotoxic plasma.

PERTURBING ACTION OF THE EARTH ON METEOR STREAMS

A paper discussing a criterion concerning the perturbing action of the earth on meteor streams by L. Kresák, of the Astronomical Observatory of the Slovak Academy of Sciences, Skalnaté Pleso (*Bull. Astro. Inst. Czechoslovakia*, 5, No. 3; 1954), deals with the possibility of the dispersion of meteor streams by the earth. He makes use of Tisserand's well-known criterion for the identity of comets which are perturbed by a comparatively close approach to a planet; this states that

$$1/a + 2\sqrt{a(1-e^2)}\cos i = C,$$

where a, e and i have the usual significance in dynamical astronomy. He then develops another criterion, the earth being the disturbing body and a meteor stream taking the place of a comet. The treatment has some advantages: for example, geocentric velocities of meteors can be determined more directly than orbital elements involved in Tisserand's criterion, and also they can be obtained directly by means of radio-echo technique. After a few substitutions and transformations of the above equation, it can be expressed in the form:

$$1/a + 2\sqrt{a(1-e^2)}\cos i = 3 - w^2,$$

where w is the geocentric velocity of the meteor; as the left-hand side of this equation is the Tisserand invariant C, the expression on the right is also constant. This shows that the geocentric velocity of a meteor is unaffected by the earth's perturbations and remains unaltered for each next encounter with the earth; the velocity vector may undergo only a reorientation. While the perturbations of the major axis may be considerable for those meteors which just escape the atmosphere, yet they appear only in a displacement of the radiant, the change of heliocentric velocity being compensated by the change of elongation of the radiant from the apex of the earth's way. In the case of meteors reaching the point of nearest approach ahead of the earth, the true and apparent radiants are shifted nearer the apex; but if the nearest approach is behind the earth, they are shifted farther from the apex.

The matter is very fully discussed in the paper and attention is concentrated on eleven of the most important meteor showers; if any observable results of the earth's action are to be found, they should be detectable in four favourable cases—in the constitution of the Taurids, Geminids, Quadrantids and Delta Aquarids—but the investigations show that the distribution of geocentric velocities does not satisfy the condition expressed above by Tisserand's equation. The conclusion is that meteor orbits are dispersed in an entirely different way from what would be expected by the earth's action. Nor can the Poynting–Robertson effect have been responsible for the arrangements of meteor orbits within the streams, and the only single factor that can be held responsible is the occasional local perturbations by the major planets acting from the time when the particles became dispersed along a portion of the original orbit.

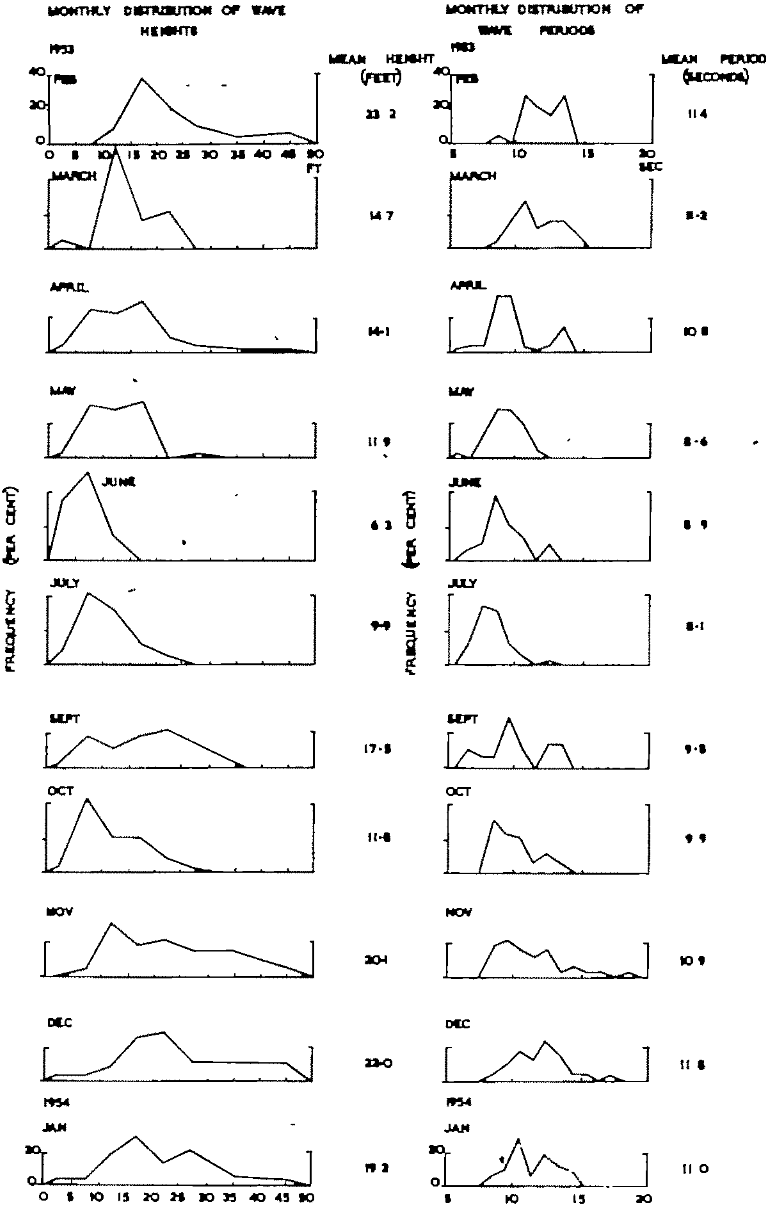

Fig. 1

WAVE CONDITIONS IN THE NORTH ATLANTIC, 1953–54

By J. DARBYSHIRE

National Institute of Oceanography, Wormley, Nr. Godalming, Surrey

WAVES have been recorded regularly in the North Atlantic Ocean by the Ocean Weather Ship *Weather Explorer* since February 1953. Wave recordings of about 8–10 min. duration are taken eight times daily using the ship-borne wave recorder already described by Tucker[1]. Sufficient results are now available to form a statistical summary of the wave characteristics.

The *Weather Explorer* occupies in turn the positions 'India' (61° 00′ N., 15° 20′ W.) and 'Juliet' (52° 30′ N., 20° 00′ W.), and observations at both positions have been combined as being representative of wave conditions generally in this part of the Atlantic Ocean. No records were obtained in August. The records were examined and the maximum height and the significant wave-period found. The significant wave-period is the mean period of the highest one-third of the waves recorded. The wave characteristics are summarized in Tables 1 and 2 and Fig. 1. Table 1 shows the percentage of time the maximum wave height is greater than 40 ft., between 30 and 40 ft., 25 and 30 ft., 20 and 25 ft., 15 and 20 ft., 10 and 15 ft., 5 and 10 ft., and less than 5 ft., for each month from February 1953 to January 1954, also the mean significant period of the waves which fall

within these height-ranges. The overall mean maximum height for each month is given in the last row.

Table 2 gives a similar survey of wave-periods, the period classes being greater than 14 sec., 13–14 sec., 12–13 sec., 11–12 sec., 10–11 sec., 9–10 sec., 8–9 sec., and less than 8 sec. The mean maximum height for waves falling in these period ranges is given, and in the last row the mean significant period for all the waves recorded during the month.

A comparison of this statistical summary with a similar one for waves recorded off Perranporth, Cornwall, during February 1946–January 1947 will be published shortly; but briefly, the comparison shows that the waves are much higher in the open ocean, the highest percentage frequency for waves of more than 20 ft. for any month at Perranporth being only 5 per cent. Longer wave-periods are, however, more frequent at Perranporth, waves with significant periods of more than 14 sec. being present for 45 per cent of the time during January 1947.

An explanation of the effect of shorter period and greater height may be found by considering the wave spectrum. It has been shown[2] that storm waves consist of a mixture of waves of various periods, and that the energy of the waves of shorter period does not increase indefinitely as the wind increases but actually tends to decrease, waves of longer period being favoured. Recent investigation has shown that this effect is not nearly so marked in the open ocean, where, as the wind increases in strength, the energy of the waves of shorter period continues to increase so that a greater proportion of the wave energy is contained in these periods. This effect would tend to reduce the mean period and increase the height. A more detailed account of this investigation will be published later.

I wish to thank the Director of the Meteorological Office and the Superintendent of the Marine Division for their co-operation; also the Master, Senior Meteorological Observer and crew of the *Weather Explorer* for making the observations.

SYNTHETIC ACTIVITY OF A SINGLE EPITHELIAL CELL OF THE LACTATING GOAT UDDER

By K. C. RICHARDSON

Department of Anatomy, University College, London

and Dr. S. J. FOLLEY, F.R.S.

National Institute for Research in Dairying, University of Reading

It would be interesting to have quantitative information about the average synthetic activity of individual cells of secretory organs in the animal body; but the work done by a single mammalian cell is not easy to estimate. The mammary gland is a secretory organ which possesses outstanding capabilities for the synthesis of protein (mainly casein), fat and carbohydrate (lactose). The development by one of us (K. C. R.) of a method for estimating the total surface area of alveolar epithelium in the goat udder makes it possible to calculate the average rate of secretion (that is, synthesis) of the three principal milk constituents by a single mammary epithelial cell in this species.

The average output of milk by the individual epithelial cells of the goat udder was calculated from the total area of epithelium lining the alveoli and intra-lobular ducts of a single mammary gland (the goat udder consists of two mammary glands), the average cross-sectional area of the individual epithelial cells and the average weekly milk yield of the gland.

The method for calculating the total area of secretory epithelium in a half-udder of the goat has already been described[1], together with results from a series of sixteen ovariectomized goats brought artificially into lactation by the administration of sex hormones and three control goats in normal lactation following pregnancy. The same sixteen experimental glands and one control have been used for the present estimations.

To determine the average cross-sectional area of the mammary cell, areas of alveolar epithelium cut tangentially to the wall of the alveolus were measured by outlining groups of cells cut in this plane and through the level of their nuclei at a constant magnification of × 1,200. The area of each group measured by a planimeter was then divided by the number of cells within the group and finally corrected for the magnification. Sufficient estimations were made from five sections of lobule-alveolar tissue, taken at random, for an average of 150 cells to be measured in each gland.

Table 1 gives the data from which the output of milk per cell per hour has been calculated. Taking the mean value for the average output of milk per cell per hour, 23×10^{-11} ml./cell/hr., and using average figures obtained by Rowland[2] for the composition of the milk of British Saanen goats from the same herd as follows: fat, 3·91 per cent; casein, 2·41 per cent; lactose, 4·07 per cent, the amounts of each constituent synthesized per cell per second calculated as outlined above are given in Table 2. In the case of lactose, the number of molecules synthesized per second can readily be calculated from this value. The figure given in the last column of Table 2 shows that the epithelial cell of the goat udder synthesizes about $4 \cdot 5 \times 10^6$ lactose molecules per second.

Table 2. RATE OF SYNTHESIS OF MAJOR MILK CONSTITUENTS BY A SINGLE CELL OF THE LACTATING GOAT UDDER

	Per cent in milk	μgm. synthesized/cell/sec.	Molecules synthesized/cell/sec.
Lactose	4·0	$2 \cdot 6 \times 10^{-9}$	$4 \cdot 5 \times 10^6$
Fat	3·9	$2 \cdot 5 \times 10^{-9}$	$4 \cdot 1 \times 10^{6*}$
Casein	2·4	$1 \cdot 5 \times 10^{-9}$	

* Saturated fatty acid molecules from butyric to palmitic, assuming all are synthesized from small molecules.

The problem of calculating the number of molecules of fatty acids synthesized per cell in a given time is a little more complicated, since goats' milk glycerides contain a 'spectrum' of fatty acids of chain-length from C_4 upwards. There is considerable evidence (see Folley[3]) that synthesis from acetate in the udder itself plays an important part in the formation of the fatty acids of milk fat, at least of the saturated series from butyric up to and including palmitic, though it is believed that oleic and stearic acids of milk fat arise principally from the blood glycerides. Taking the figures given by Gamble, Ellis and Besley[4] for percentages of the various fatty acids in the total fatty acids of goat milk fat and assuming that the total fatty acid content of goats' milk fat is of the order of 90 per cent, the numbers of molecules of each saturated fatty acid from butyric to palmitic synthesized by a single cell each second were therefore calculated on the assumption that the whole of these acids are synthesized in the udder from acetate. The total, just over 4×10^6 molecules per second, happens to be very close to the figure for lactose. If one accepts the mechanism for the synthesis of milk fatty acids postulated by Popják, French, Hunter and Martin[5], namely, that they are formed by successive condensation of 2-carbon units, and neglecting any utilization of preformed 4-carbon units entering from the blood which would scarcely affect the calculation, the figure obtained for the rate of synthesis of the saturated fatty acids (C_4–C_{16}) corresponds to about $21 \cdot 5 \times 10^6$ condensations/sec./cell.

No attempt has been made to calculate the rate of synthesis of casein molecules owing to uncertainty about the molecular weight of casein.

It should be pointed out that the figures given in Table 2 represent average rates of synthesis calculated over twenty-four hours. The rate of milk secretion is, however, not constant; it is relatively rapid just after milking and then slows down as the udder fills with milk. The maximum rates are therefore certain to be considerably greater than the average rates given in the table.

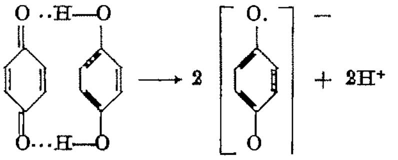
Stabilization of Free Radicals by Adsorption: Detection by Paramagnetic Resonance

It is known that quinhydrones are weak acids and may therefore form ions in strongly alkaline solutions. Due to the loss of two hydrogen atoms of the quinhydrone compound, two identical semiquinone ions can be expected; for example:



(I) Quinhydrone (II) Semiquinone

These semiquinone ions, having an odd number of electrons, should be paramagnetic. Michaelis has proved the existence of free radical ions of this type during alkaline reduction of phenanthrene-quinone-3-sulphonate[1] by potentiometric and magnetic measurements. It would be difficult to demonstrate the existence of free radical ions in the case of many quinhydrones, for example, p-benzoquinhydrone, as they are too unstable in alkaline solution. It occurred to us, however, that it might be possible to stabilize such unstable radical ions by adsorption of quinhydrone on suitable basic surfaces. A sufficiently basic surface could have the same effect as the alkaline solution, and the adsorption might stabilize the free radicals formed.

To test this idea we adsorbed p-benzoquinhydrone on barium hydroxide octahydrate, using solutions in various non-polar solvents (dioxane, benzene). An intense blue colour appeared on the surface. Solutions of pure p-benzoquinone and pure hydroquinone gave rise to no colour on adsorption, nor was this colour formed when alumina or silica gel was used for adsorption of p-benzoquinhydrone.

Paramagnetic resonance[2,3] experiments on the coloured surface showed it to be paramagnetic. Our measurements were made on the powder at 90° K. Neither barium hydroxide nor solid p-benzoquinhydrone alone showed paramagnetism. The paramagnetic resonance consisted of a single absorption line, a few gauss wide and with $g = 2{\cdot}003 \pm 0{\cdot}001$. This is typical of the resonance obtained from a free radical. Thus it seems reasonable to conclude that our experiments demonstrate the formation and stabilization of free radical-semiquinone ions on an alkaline surface.

Since quinhydrone splits up into a rather complicated equilibrium system in solution[4], a similar situation may arise on the barium hydroxide surface, and other paramagnetic ions and molecular compounds may be present. Because the paramagnetic resonance spectra of different free radicals are so similar, we cannot conclude from our experiments that only ions of one type, such as (II), are formed.

It is noteworthy that anhydrous barium hydroxide is only slightly coloured by a solution of p-benzoquinhydrone. If, however, one adds a few drops of water to the solution, the deep colour appears at once. Thus it seems that the hydrate water molecules are necessary to promote adsorption and formation of ions. A similar case of the effect of water on the production of coloured surfaces has been reported by Schoenberg[5]. We think this is because the strong dipole moment of the water molecules facilitates dissociation.

We have also adsorbed three other quinone–hydroquinone systems on barium hydroxide and investigated the paramagnetism. Table 1 shows the combinations on which we have made measurements, dioxane being used as a solvent. In all cases a deeply coloured surface was formed. Paramagnetism was present in all cases, even with phenanthrenequinone when the corresponding hydroquinone was not used. Here the formation of two different radical ions is to be expected, but our experiments do not distinguish between different types of radical. Adsorbed anthrarufin and quinizarin did not show paramagnetic resonance. This is not surprising; paramagnetism is not expected, since these compounds can form a quinhydrone system within the molecule.

Table 1

Quinhydrone system Quinone	 Hydroquinone	Colour after adsorption	
p-Benzoquinone	p-Benzohydroquinone	Deep blue	Paramagnetic
Thymoquinone	Thymohydroquinone	Blue-green	,,
Phenanthrenequinone	Phenanthrenehydroquinone	Green	,,
Phenanthrenequinone	p-Benzohydroquinone	Blue-green	,,
Anthrarufin		Purple	No paramagnetic resonance
Quinizarin		Purple	,,

The paramagnetism found in our experiments indicates that the adsorbed molecules lose hydrogen ions to the alkaline surface. It is interesting that Weitz[6] found that the colourless triaminotriphenylmethanol (a weak base) is adsorbed on silica gel, which is acidic, with nearly the same colour as the corresponding dye salt. He ascribes this to the formation of ions by loss of hydroxyl ions to the surface.

Goldschmidt and Christmann[7] studied the reaction of quinhydrones with sodium methylate and obtained unstable blue products which contain about two sodium atoms per quinhydrone molecule. We consider it possible that Goldschmidt's products contain ions similar to the radical ions we have obtained on the coloured surfaces. In this case one should consider them as free-radical salts.

It may be that a stabilization of free radicals on a suitable surface occurs in biological systems. For example, Kaye and Stonehill[8] give polarographic evidence that many substances of physiological importance form unstable free radicals, and they stress the importance of these in biochemical processes. Such radicals might be stabilized by acidic or basic surfaces, for example, suitable proteins.

Isotopic Exchanges and the Existence of Tricalcium Phosphate in Bone

THE problem of the physico-chemical constitution of the skeleton has received considerable attention in recent years[1-8]. Tracer experiments indicate that phosphorus-32 and calcium-45 appear promptly and in considerable proportions in the bony tissues, whence they are removed slowly[4-6]. These observations have led to an assumption that deposition of phosphorus-32 and calcium-45 in bony tissues is an exchange between bone and blood inorganic phosphate or calcium. Phosphorus-32 and calcium-45 have been used to study phosphate or calcium exchange between powdered bone and aqueous disodium hydrogen phosphate and calcium chloride solutions[7-9]. Different authors[6,10,11] have concluded that the principal bone component is not tricalcium phosphate but rather hydroxylapatite to which phosphoric ions are adsorbed in such a quantity that the ratio of calcium to phosphorus is equal to 1·94, which is the characteristic value for tricalcium phosphate. On the other hand, the findings of some workers[1,2] support the idea of the existence of tricalcium phosphate in bony tissues. The experiments reported here are an attempt to study the exchange mechanism of both phosphate and calcium between pure tricalcium phosphate and radioactive phosphate or calcium solutions. These experiments were also performed in order to show to what extent the isotopic exchange method can help to elucidate a particular problem of structural chemistry. (Calcium-45 was prepared by neutron bombardment in the pile at the Clinton Laboratories, Oak Ridge, Tenn., and phosphorus-32 at the pile at Harwell, Berks.)

In the first series of experiments, the tricalcium phosphate was prepared by mixing disodium hydrogen phosphate and calcium chloride in the presence of ammonia. Later, the tricalcium phosphate was prepared as follows: calcium oxide dissolved in water was added to dilute phosphoric acid with phenolphthaleine as indicator; the excess of calcium hydroxide was neutralized by one or two drops of dilute phosphoric acid. Phosphate was determined by the method of Fiske and SubbaRow. Calcium determinations were done by precipitation as calcium oxalate and titration by means of potassium permanganate. Radioactive measurements were made with a thin-wall end-window counter tube.

125 mgm. samples of tricalcium phosphate were exposed to 5 ml. of radioactive disodium hydrogen phosphate or calcium chloride solutions for increasing lengths of time up to sixty days. The sealed 'Pyrex' tubes containing the samples were rotated end to end continuously at 40 r.p.m. In most experiments the tests were repeated several times. Experiments were performed at 18°, 60°, 120° and 180°. The quantities of calcium or phosphorus in both phases were the same. 100 per cent of the calcium-45 and phosphorus-32 was in the solution initially and 0 per cent was in the tricalcium phosphate. At the end of each reaction period, solid and solution were separated by filtration; the same results are obtained when separation is performed by dialysis. The solid was dissolved in 5 ml. of hot 3 *N* hydrochloric acid and aliquots were taken for chemical and radioactive measurements. All the samples were counted after evaporation to dryness under an infra-red lamp. The extent of exchange was calculated in the usual manner from the specific activities of the two fractions. Some calcium phosphate samples were equilibrated for three days at 18° or 180° with radioactive solutions, at which time the latter were replaced with inert phosphate or calcium solutions and further equilibrated for an additional three days. The exchange was also studied with tricalcium phosphate ignited at 900°.

Typical results are shown in Fig. 1. For each temperature, the exchanged fraction increases rapidly in the first two hours; this rapid increase is succeeded by a much slower increase. Analytical determinations indicate that the deposition of calcium-45 and phosphorus-32 in the calcium phosphate had not been accompanied by a proportionate net deposition of the non-radioactive calcium or phosphate. No linear relationship was apparent when the logarithms of the differences between percentages exchanged at any time and at 'equilibrium' are plotted as ordinates

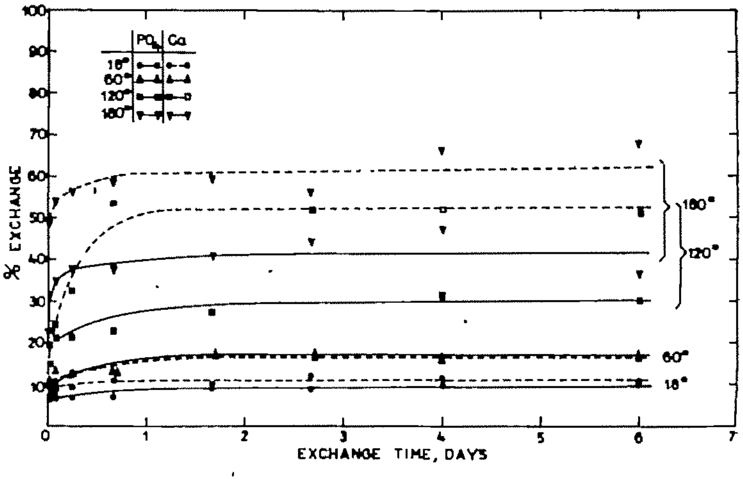

Fig. 1

against time. The exchange results do not obey a simple exponential law; it is possible to obtain curves analogous to radioactive decay curves.

The curves obtained indicate three processes to each of which corresponds a half-time for the exchange. The exchange percentages are increased with temperature. Temperature variations affect such processes as recrystallization and self-diffusion. At room temperature, the exchange could be attributed partly to adsorbed phosphoric ions ($\simeq$ 10 per cent); it cannot explain, however, the important exchange at higher temperatures. For temperatures higher than 60°, the calcium exchange is greater than the phosphate.

Results indicate a marked lack of reversibility, which is to be expected when recrystallization takes place. Ions fixed in the interior of the newly formed crystals are no longer available for exchange. Similar results were obtained by Neuman[8] with fresh bone, whereas ashed bone showed such a reversibility as reported by Falkenheim[7,9].

A lack of exchange is observed with tricalcium phosphate ignited at 900° and with large crystals of hydroxylapatite. Again, crystals are affected by heat treatment, which results in crystal growth and a more stable crystal lattice.

The time exchange curves were somewhat different for the individual phosphate preparations. Isotopic exchange, at least in the rapid exchange process, is concerned with crystal surfaces which will vary considerably for different calcium phosphate preparations. Also, heat treatment results in crystal growth, which reduces the crystal surface and at the same time the exchange. Furthermore, the exchange of both calcium and phosphate ions may involve other mechanisms such as recrystallization and self-diffusion.

When radioactive phosphate and calcium are administered to animals, it is clear that the mechanisms by which these ions are fixed by the skeleton are complex. It would be difficult to estimate the rates at which real exchange and both recrystallization and self-diffusion take place *in vivo*.

The lack of exchange by large crystals of hydroxylapatite, the same behaviour of both calcium and phosphate ions at 18°, and the important exchange observed at higher temperatures, seem to exclude that the exchange concerns adsorbed phosphate ions already present in the solid phase when experiments are started. Hence our results cannot support the assumption that the principal bone component is hydroxylapatite, which adsorbs phosphate enough to give a calcium/phosphorus ratio of 1·94.

Isolation and Structure of an *N-iso*Butyldienediynamide from Pellitory (*Anacyclus pyrethrum* DC.)

THE roots of the North African plant *Anacyclus pyrethrum* DC. (pellitory) have been used in medicine since the time of Dioscorides, and mention of the drug is made in the B.P.C. 1934 (*Pyrethri radix*). It induces copious salivation when chewed and gives rise to an intense burning taste. In a recent investigation it has been found[1] that the crystalline sialogogue isolated by Gulland and Hopton[2] from this material, and named pellitorine (melting point 72°), is in fact a mixture of *iso*butylamides[3,4] of the general type

$$R.CH{=}CH.CH{=}CH.CO.NHCH_2CH(CH_3)_2. \qquad (1)$$

Hydrogenation and acidic hydrolysis yield a mixture of decanoic, dodecanoic and tetradecanoic acids which can be separated by reversed-phase partition chromatography. Its nature will be discussed more fully elsewhere. During the isolation of pellitorine, a new crystalline substance of melting point 121° has been obtained, which crystallizes from chloroform–petrol in white needles. Unlike pellitorine, it is but sparingly soluble in petrol, has no sialogogue effect and only low insecticidal activity towards the grain insect *Tenebrio molitor* L.

The new substance, 'anacyclin', has the empirical formula $C_{18}H_{25}ON$ (found: C, 79·7; H, 9·2; N, 5·2. $C_{18}H_{25}ON$ requires C, 79·9; H, 9·3; N, 5·15 per cent. Molecular weight (Rast) 284), and absorbs 6 mol. of hydrogen on catalytic hydrogenation to give dodecahydroanacyclin, melting point 66°. The infra-red spectrum (paraffin mull) indicates that this is a saturated monosubstituted amide (NH str. 3,310, 3,075; amide *A* carbonyl 1,641; amide *B* 1,548 cm.$^{-1}$), while the spectrum of anacyclin itself is characteristic of a monosubstituted amide conjugated with a diene system (NH str. 3,300, 3,060; amide *A* carbonyl 1,625; amide *B* 1,544; C=C str. 1,655, 1,612 cm.$^{-1}$). The ultra-violet absorption (λ_{max} 259 mμ, ϵ_{max} 33,500) is in agreement with data expected for a chromophore —CH=CH.CH=CH.CO.NH—. Hydrolysis of dodecahydroanacyclin gave *iso*butylamine (hydrochloride) and tetradecanoic acid (*p*-bromophenacyl ester), and its identity as *N*-*iso*butyltetradecanamide was confirmed by synthesis. Anacyclin itself gave *iso*butylamine on hydrolysis, so the structural problem resolves itself into placing unsaturation equivalent to four molecules of hydrogen in the chain of the acid fragment, and clarifying the stereochemistry.

Anacyclin gave an adduct with maleic anhydride (melting point 193° decomp.) which on catalytic hydrogenation absorbed five molecules of hydrogen. In this adduct the dienamide chromophore is eliminated, and when its ultra-violet absorption spectrum was determined, a series of bands became apparent (λ_{max} 227; 237; 252; 266; 281 mμ. ϵ_{max} 1,850; 1,300; 1,100; 1,000; 850). These are characteristic of a diyne containing about 4 per cent of enediyne impurity. Confirmation of acetylenic linkages was obtained from the presence of two weak C≡C str. bands in the infra-red (2,233 and 2,206 cm.$^{-1}$). Their weakness is consistent with lack of conjugation with a polar grouping. The maleic adduct had weak bands at 2,243 and 2,208 cm.$^{-1}$.

The position of the diyne system was determined by oxidative degradation with permanganate. This yielded *N*-*iso*butyloxamic and succinic acids, together with butyric acid (*S*-benzylthiuronium salt) and leads to structure (2):

$$CH_3(CH_2)_2.C{\equiv}C.C{\equiv}C.CH_2CH_2.CH{=}CH.CH{=}CH.CO.NHCH_2CH(CH_3)_2. \quad (2)$$

The formation of an adduct with maleic anhydride indicates a *trans-trans*-configuration for the 2 : 4-diene system. Unpublished reference data[1] obtained from a recent study of the four stereoisomeric *N-iso*-butyldeca-2 : 4-dienamides show that the position of the C=C stretching frequencies in anacyclin, the possession of a band at 996 cm.$^{-1}$ and the absence of one at 960–965 cm.$^{-1}$, are characteristic of the above configuration. The ultra-violet extinction coefficient of anacyclin is also in agreement. Anacyclin is thus *N-iso*butyltetradeca-*trans*-2 : *trans*-4-diene-8 : 10-diynamide.

If methyl deca-2 : 4-diynoate is semi-hydrogenated in the presence of quinoline, using lead-poisoned palladium catalyst[5], the main product is methyl deca-*cis*-2 : *cis*-4-dienoate[1]. When anacyclin is allowed to absorb two molecules of hydrogen under these conditions a waxy crystalline product can be isolated which, on the basis of the above information and its ultra-violet absorption, is formulated as *N-iso*butyltetradeca-*trans*-2 : *trans*-4 : *cis*-8 : *cis*-10-tetraenamide. This unstable compound is very soluble in light petrol, is a strong sialogogue and has a high toxicity towards *T. molitor*. The last finding is of considerable interest because of the light it throws on the structure and stereochemical requirements for a potent polyene-amide insecticide.

The insecticidal testing was carried out by Dr. M. Elliott and Mr. P. Needham, Department of Insecticides and Fungicides, Rothamsted Experimental Station.

Isolation and Structure of Neo-Herculin from *Zanthoxylum clava-herculis* L.

Southern prickly ash bark (*Zanthoxylum clava-herculis* L.) contains a potent insecticidal substance, which was named herculin (m.p. 59–60°) by Jacobson[1] and claimed to have structure (I). This structure has been disproved[2,3] by syntheses of the four possible stereoisomers of (I), which have different physical characteristics and negligible physiological activity.

$$\text{(I)}\ CH_3CH_2CH_2.CH{=}CH.CH_2CH_2CH_2CH_2.CH{=}CH.CO.NHCH_2CH(CH_3)_2.$$

$$\text{(II)}\ CH_3CH{=}CH.CH{=}CH.CH{=}CH.CH_2CH_2.CH{=}CH.CO.NHCH_2CH(CH_3)_2.$$

A highly unstable but pure compound (m.p. 70°) named *neo*-herculin has now been isolated from the bark and shown to have structure (II). It is very toxic to *Tenebrio molitor* and houseflies and seems to be the major crystalline insecticidal substance present. *neo*-Herculin has the empirical formula $C_{16}H_{25}ON$ (found: C, 77·3; H, 10·2; N, 5·7. $C_{16}H_{25}ON$ requires: C, 77·65; H, 10·2; N, 5·65 per cent) and on microhydrogenation absorbs 3·75 mol. of hydrogen. A mono-substituted amide linkage is present (infra-red absorptions: NH, 3,260, 3,070; amide *A*, C=O, 1,626; amide *B*, 1,559 cm.$^{-1}$). *neo*-Herculin gave *iso*butylamine (hydrochloride, chloroplatinate) on acidic hydrolysis: this demonstrates that unsaturation is contained only in the acid fragment. The carbon skeleton is revealed by the identity of octahydro *neo*-herculin (m.p. 53–54°) with lauric *iso*butylamide.

Ultra-violet light absorption data ($\lambda_{max.}$ 259, 269, 280 mμ; $\epsilon_{max.}$ 31,500; 43,500; 36,200) demonstrate a conjugated triethenoid chromophore. Subtraction of the curve for α-elaeostearic acid leaves an absorption of λ 9,000 at ε 227 mμ, and this indicates that the fourth double bond is to be found α to the amide linkage. Its position is confirmed by the strength of the ethenoid stretching vibration at 1,670 cm.$^{-1}$ in the infra-red[2]. Location of the triene system in the chain was effected by ozonolysis, which yielded acetaldehyde. *neo*-Herculin is therefore N-*iso*butyl-dodeca-2 : 6 : 8 : 10-tetraenamide (I).

Infra-red observations suggest that the αβ-double bond is *trans*-, but the stereochemistry of the triene system cannot be completely defined. *neo*-Herculin does not give a crystalline derivative with maleic anhydride, so two contiguous *trans*- linkages are likely to be absent. The relatively low extinction coefficients in the ultra-violet are consistent with this view[4].

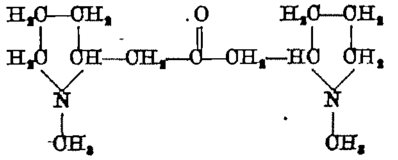
Cuscohygrine, a Normal Constituent Alkaloid of *Atropa belladonna*

In an earlier communication on alkaloids in germinating seeds of *Atropa belladonna*[1], we mentioned that a new alkaloid was the first to appear on paper chromatograms using Dragendorff's reagent. As this alkaloid was always found on chromatograms of extracts of fresh root material and no information about its nature was available, it seemed worth while to make a further investigation.

Starting with 20 kgm. dried roots, about 100 mgm. of a picrate was obtained, which was analysed: melting point, 215° C.; molecular weight, 230; elementary analysis, C, 44·7, H, 4·5, N, 16·1 per cent.



Cuscohygrine

These results, combined with decomposition experiments, which showed it to be a pyrrolidine derivative, led to the conclusion that the substance was cuscohygrine, hitherto only found accompanying coca alkaloids.

This fact was confirmed by comparison with synthetic cuscohygrine (chromatography).

Chromatographic analysis showed it to be present in the roots of the following species: *Atropa belladonna, Hyoscyamus niger, Datura stramonium, D. innoxia, D. ferox, D. metel, Scopolia lurida, S. sinensis, Physochlaina orientalis, P. physaloides* and *Mandragora officinalis*.

This discovery sheds a new light on the role of pyrrolidine derivatives in the biochemistry of the tropane alkaloids, which will be discussed elsewhere.

I wish to thank Prof. F. Galmovsky, University of Vienna, for providing a sample of synthetic cuscohygrine.

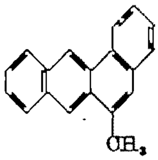
A Novel Synthesis of 4-Methyl-1 : 2-Benzanthracene

Of the various alkylbenzanthracenes, 4-methyl-1 : 2-benzanthracene aroused considerable interest through its pronounced carcinogenic activity[1]. The literature includes a few syntheses of this hydrocarbon[2], but these methods are laborious since they involve numerous steps. We have now worked out a new route to this hydrocarbon in four steps starting from 2-allyl*cyclo*hexanone and tetralin, based on the method developed by Mukherji and co-workers[3] for the synthesis of polycyclic aromatic hydrocarbons.



2-Allyl*cyclo*hexanone was made to react with tetralin in the presence of anhydrous aluminium chloride at 0–5° C., and 2-(β-methyl-β-(6-tetralyl)-ethyl)-*cyclo*hexanone (boiling point 210–215°/6 mm.; η_D^{32} 1·5578) was obtained in 70 per cent yield. Reduction of this ketone with aluminium *iso*propoxide in *iso*propyl alcohol gave the corresponding carbinol (boiling point 190–195°/3 mm.; η_D^{32} 1·5585) in almost quantitative yield. This carbinol was cyclized with concentrated sulphuric acid (1·84) to the corresponding dodecahydro-1 : 2-benzanthracene derivative (boiling point 190–195°/6 mm.; η_D^{30} 1·5600), which was smoothly dehydrogenated with palladium-charcoal (30 per cent) at 300–320° C. for 4 hr. to give 4-methyl-1 : 2-benzanthracene which (purified by regeneration from its picrate) crystallized from alcohol in pale yellow needles (melting point 123–124° C.; lit. (ref. 2*a*) melting point 124–124·6° C.).

The picrate crystallized from alcohol as brown-red needles (melting point 148° C.; calc. for $C_{25}H_{17}N_3O_7$: N, 8·91; found: N, 8·68; lit. (ref. 2*a*) melting point 148–149° C.).

The hydrocarbon gave a trinitrobenzene derivative which crystallized from alcohol as red needles (melting point 168° C.; calc. for $C_{25}H_{17}N_3O_6$: N, 9·23; found: N, 9·03; lit. (ref. 2*a*) melting point 163–164° C.).

Details of this work will be published elsewhere. The microanalyses were carried out by Drs. G. Weiler and F. B. Strauss (Oxford).

Significance of Metallic Transfer in Orthopædic Surgery

In an earlier communication[1] attention was directed to the transfer of metal which can occur between a screwdriver tip and a screw head during the operation of screwing, and the possible significance this might have in orthopædic surgery was discussed. It was demonstrated by a radioactive tracer method that, whenever a screw is inserted, small fragments of metal are plucked out of the driver and remain adhering to the screw head. It was suggested that, although the amount of metal transferred is very small (about 10–100 μgm.), the particles may form corrosion centres and cause metal ions to pass into the surrounding tissue. This may cause tissue reaction and interfere with normal physiology even in cases where no gross corrosion is observed.

In our earlier work, the presence of abnormally high concentrations of iron in the tissues surrounding buried metals was demonstrated by staining microtome sections of biopsy specimens to give the prussian blue reaction. Recently, biopsy samples of such tissue have been analysed spectroscopically for us by Dr. A. H. Gillieson, of the Atomic Energy Research Establishment, Harwell. The quantities found were compared with the normal concentration of these ions in tissue[2]. All the samples were taken from regions adjacent to stainless steel plates and nails which had been buried in the body for three to four months. None of the cases showed visual evidence of corrosion. The results show that the tissues adjacent to parts of the metal handled with tools during its insertion are abnormally rich in the ions of its constituents. Concentrations up to five times normal were found. The tissues near unhandled parts of the buried metal, however, had ionic concentration not significantly different from normal.

These results confirm quantitatively the picture suggested by examination of the stained microtome sections of tissue, and show clearly that considerable quantities of the ions of the so-called inert metal pass into the surrounding tissues, and that this dissolution is greatest from regions which have been handled with tools during the insertion of the metal.

The amount of metallic transfer depends on the relative hardness and the specific nature of the contacting surfaces[3]. The effect of the hardness of the tool has recently been investigated quantitatively.

Samples of medical drivers and screws have been treated to alter their hardnesses, and the amounts of transfer occurring with various combinations have been measured. The table shows the relative amounts of transfer observed. These figures should be regarded as approximate only, as the amount of transfer showed large variations. All the samples of orthopædic drivers and screws examined had hardnesses of about 150 and 380 V.H.N. respectively, and the transfer under these conditions has been taken as unity. Clearly, the transfer may be reduced appreciably by increasing the hardness of the drivers or softening the screws.

DEPENDENCE OF THE RELATIVE AMOUNT OF TRANSFER ON THE HARDNESSES OF DRIVERS AND SCREWS

	Steel driver, 150 V.H.N.	Steel driver, 360 V.H.N.
Steel screw, 380 V.H.N.	1	$\frac{1}{10}$
Steel screw, 133 V.H.N.	$\frac{1}{2}$	$\frac{1}{16}$

It does not necessarily follow, however, that the smallest electrolytic action will occur when a hard tool is used; although a hard tool will reduce the metallic transfer, it will cause increased mechanical deformation of the oxide layer on the screw and may thus affect the inertness of the metal. Further experiments would be necessary to determine the relative importance of these two factors.

These experiments again indicate that some attention should be given to the tools used in orthopædic surgery, as well as to the buried metal.

We wish to thank Dr. A. H. Gillieson, of the Analytical Laboratory at Harwell, for his aid in the analysis of the biopsy samples.

A Modified Wedge Method for exciting Shear Modes in Isotropic Media

THE wedge method developed by Bhagavantam and Bhimasenachar[1] has been very useful in the determination of elastic constants of solids. But very often it is found to be difficult to excite and identify the shear modes for the transmission maxima, as they are very weak and are of the same order of intensity as the spurious frequencies of the wedge. However, it has been pointed out[2] that, if small thin specimens are used, shear modes could also be excited, although feebly, due to edge coupling. Recently[3], it has been reported that shear modes cannot be excited in rocks which are coarse-grained and heterogeneous in composition. The method presented here describes a simple modification of the wedge method for exciting and identifying easily only the shear modes in isotropic media and thus overcoming the difficulties inherent in the normal wedge method.

The experimental arrangement consists of the usual Debye–Sears equipment for observing diffraction due to transmission maxima of the section under investigation using an X-cut quartz wedge as a continuous-frequency source. The modification introduced is that the specimen under investigation is placed at an angle to the incident sound wave-front instead of in contact with the wedge as in the usual method. By keeping the plate at an angle, the component of the impinging force that contributes to the shear stress on the specimen will increase and hence the shear modes can be excited intensely. By adjusting this angle to be greater than the critical angle for total reflexion of longitudinal waves in the plate, only transmission maxima due to shear modes are observed with an intensity equal to that of the longitudinal modes for normal incidence. The frequencies at which transmission maxima are observed correspond to the fundamental or harmonic of the shear modes in the plate placed at the appropriate angle. The shear velocity V' in the specimen is determined by using Rayleigh's expression for the condition of maximum transmitted energy at oblique incidence, namely:

$$\sin^2\varphi = (V/V')^2 - (V/2d\,.\,n/\nu)^2,$$

where φ is the angle of incidence of the sound beam on the plate, V the velocity of sound in the liquid in the diffraction cell, d the thickness of plate, n the order and ν the frequency of observed transmission maxima.

Results thus obtained for the shear velocities in some common metals and rocks are given in the accompanying table along with the values obtained by some other methods. All the sections are placed at an inclination of 25°.

Specimen	d (mm.)	$\frac{\nu}{n}$ (Mc./sec.)	Shear velocity (m./sec.)	Velocities obtained by other methods
Aluminium	0·83	2·859	2,843	2,820 (ref. 4)
Brass	0·80	1·651	2,032	2,024 (ref. 2)
Granite	1·18	1·164	2,113	2,370 (ref. 5)
Syenite	1·06	1·414	2,315	2,754 ,,
Shale	0·97	1·463	2,217	2,270 ,,

The advantage of this method is that no difficulty is experienced in identifying shear modes, as they are excited very intensely and the longitudinal modes are eliminated. The accuracy of these determinations is the same as in the normal wedge method. However, the large breadth of resonance present, particularly in coarse-grained rock sections, may lead to slight inaccuracy. But where it is very difficult to excite shear modes at normal incidence, this method is definitely advantageous. The method is at present limited to isotropic media. Full details will be published elsewhere.

Formation of Compact Pieces of Grey Tin

In a previous communication[1] the formation of compact pieces of grey tin was announced. A spectrophotometrical analysis of the material used indicated the presence of mercury, a metal which does not occur in natural tin. Consequently, the presence of mercury must be responsible for the behaviour of this specific material. This fact led to an investigation of the properties of tin–mercury alloys.

According to the literature[2], addition of more than 2 atomic per cent mercury forms a two-phase system, the phases being tetragonal and hexagonal, the composition of this latter being given as $HgSn_{12}$. At 8 atomic per cent mercury, the tetragonal phase disappears.

We prepared tin–mercury alloys, in the range 0·03–6 atomic per cent mercury, by melting in vacuum. X-ray photographs, taken after annealing, showed the presence of the hexagonal phase already in alloys with more than about 0·2 atomic per cent mercury, that is, at much lower mercury contents than given in ref. 2.

All amalgams showed at − 20° C. an increased rate of transition as compared with that of pure tin (Johnson-Matthey). Above 0·2 atomic per cent mercury the grey tin formed is compact. X-ray photographs showed that the tetragonal tin phase is transformed into the cubic grey modification, whereas the hexagonal phase is still present after the transition in the two-phase system. It might be suggested that the hexagonal phase acts as a matrix, holding the particles of the grey tin together; but microscopical studies have provided so far no evidence in favour of this suggestion.

The presence of a few tenths per cent of mercury increased also the rate of transition of other samples of tin, among them commercial grade tin and even samples of tin containing a small quantity of lead, for example, 0·03 per cent, or 0·1 per cent bismuth. This latter is the more remarkable as these two metals themselves decrease the rate of transition. In all these cases compact pieces of grey tin were formed. Pieces measuring several centimetres in length and about 0·5 cm. thick were obtained in this way.

External Metasomatism associated with Serpentine

After finding in Turkey that many geosynclinal serpentines appear to be submarine lava flows[1], we re-examined in Ayrshire the only known exposure of an actual contact between the Ballantrae serpentine and associated spilites. The evidence is difficult to disentangle, but it proved beyond doubt that the serpentine is earlier than the particular spilite concerned[2], not vice versa as had previously been supposed. Full publication has been delayed. Here we only wish to emphasize that the spilite, though the later of the two rocks, is strikingly altered for a distance of some few inches in from the contact, and that it is penetrated by some minute veins of serpentinous material, some of which also clearly cut the serpentine itself. Away from the contact the spilite is an olive-green rock, dappled with very pale grey, or whitish, felspars. In its altered border-zone, which has an almost abrupt boundary, it turns reddish, sometimes purplish, with areas that are much paler; and its felspars are completely pseudomorphed by dark green translucent material that appears darker, instead of paler, than the matrix.

Under the microscope, the red coloration of the altered base is seen to be due to a close precipitation of iron ore powder. The paler areas are rich in leucoxene. The pseudomorphed felspars are replaced by some mineral of the chlorite-serpentine category, which also seems to furnish the main constituent of the base.

One important conclusion which we drew was that the parent peridotite of the serpentine still contained fresh olivine when the spilite came into contact with it, for serpentinization of olivine seems to us the only possible source of the magnesian solutions responsible for the alteration of the spilite. Analogies with the development of white trap and of spilite itself are sufficiently obvious. The interest of the occurrence has been greatly enhanced by two subsequent descriptions of almost identical alteration in France. Vuagnat[3] has described the phenomenon in a spilitic pillow–lava–agglomerate with fragmental serpentine matrix in the Montgenèvre district of the High Alps, 180 km. south-south-east of Geneva; and Vuagnat and Jaffé[4] in a "conglomerate", as they call it, containing many spilitic fragments in a "sorte de purée de serpentine", 2 km. east-north-east of Gets in the Prealps, 40 km. east from Geneva. These authors are as clear as ourselves that the alteration in the spilitic material is due to interaction with magnesian solutions. As regards the origin of the serpentine of the matrix, they are non-committal. We are, however, assured that some of the fragments in the matrix of the Montgenèvre occurrence show the typical mesh-structure of normal serpentine along with the usual bastite plates.

The new work carried out at Geneva is backed by rock analyses. These confirm, what is self-evident, the metasomatic nature of the alteration of the spilitic material. They also demonstrate that the main mineral (or minerals) produced is aluminous, and therefore chlorite rather than serpentine.

Measurement of the Refractive Index of Cytoplasmic Inclusions in Living Cells by the Interference Microscope

A method of measuring the refractive index of living cytoplasm by phase-contrast microscopy was recently developed by Dr. R. Barer and his associates[1,2]. This method consisted essentially of suspending cells in an isotonic protein medium of the same refractive index as the cytoplasm, which then, by phase-contrast, appeared to match the background in brightness and consequently was almost invisible. This formed the starting-point for the present investigation. Phase-contrast cannot normally be employed for the refractometry of cytoplasmic inclusions, since the refractive index of the cytoplasm that surrounds them cannot be varied at will like that of the medium in which the cells are suspended. When the cytoplasm matches the suspension-medium in brightness, a cell-inclusion that appears brighter will generally have a lower refractive index than the cytoplasm, and conversely; but no accurate quantitative estimate can be made.

With the interference microscope, on the contrary, it is possible to measure the actual phase changes produced by objects, and it recently occurred to me that, by its aid, the technique developed by Dr. Barer and his associates might be extended so as to measure the refractive index of cytoplasmic inclusions.

For the present investigation the double-refracting interference microscope of Messrs. Charles Baker was used, and the cytoplasmic inclusion chosen for testing the technique was the spherical *Nebenkern* in the developing spermatid of *Locusta migratoria*. This body is formed during spermatogenesis by the aggregation of all the mitochondria, and has the advantage of being a relatively large, nearly spherical body, lying in an almost completely clear cytoplasm. Also, since it consists mainly of protein and lipoprotein, a fairly close approximation of its water and solid content can be arrived at by assuming a refraction increment (α) of 0·0018 provided that its refractive index can be determined[1-4].

To prepare a suspension-medium that would have exactly the same refractive index as the cytoplasm of the cell, cells were suspended in suitable saline media to which varying amounts of bovine plasma albumin were added. The analyser of the microscope was turned to give a red background with unfiltered light from a ribbon-filament lamp. It was found that when the suspension-medium had a refractive index of 1·3535, the cytoplasm of the spermatids showed exactly the same red colour, and therefore nearly disappeared. This suspension medium was therefore used throughout. (By this method, a variation in the refractive index of the cell cytoplasm of 0·0009, or approximately 0·5 per cent of solid, could be detected without any difficulty.)

The *Nebenkern* was shown by the Becke test to have a refractive index higher than that of the cytoplasm. Under the interference microscope, it naturally appeared in a different colour from the cytoplasm and suspension medium. The phase-shift that caused this difference was measured with light from the same source but filtered through an Ilford 807 filter. This gave a narrow spectrum with (measured) maximum intensity at about 542 mμ. The 2-mm. double-focus objective was used. The analyser was first turned so as to darken the suspension medium and cytoplasm as much as possible, and then the phase-change due to the *Nebenkern* was measured by turning the analyser until the centre of the *Nebenkern* had become as dark as possible. From the measurement of the angle of rotation, it was possible to obtain a value for phase-difference to a fiftieth of a wave-length (or more accurately than this).

The *Nebenkern* being approximately spherical, its maximum depth along the optical axis of the microscope can be taken as being the same as that at right-angles to the optical axis. It is probable that in no case was the error of this measurement greater than 0·4 μ.

The refractive index, n, of the *Nebenkern* was calculated from the formula:

$$n = \frac{\theta}{360} \times \frac{\lambda}{t} + m,$$

where θ is the phase-change due to the *Nebenkern*, expressed as an angle, λ the wave-length of the light used (taken as 542 mμ), t the thickness (diameter) of the *Nebenkern*, and m the refractive index of the cytoplasm and suspension medium (1·3535, equivalent to about 10·7 per cent of solid).

Table 1 shows the values for the refractive index of the *Nebenkern* derived from measurements of this body in twenty different cells. The mean figure is 1·376. This suggests that the concentration of protein and lipoprotein in this cytoplasmic inclusion is on the average about 23 per cent. Even in adjacent cells, *Nebenkerns* having the same diameter were sometimes found to give appreciably different phase-changes; and this could indeed be expected, since the mitochondria only gradually coalesce to form a single body. Part of the variation in the refractive index of the *Nebenkern* was thus due to variation in the material itself. It is difficult to assess the actual error of the technique. Error is more likely to arise from measurement of the diameter than from measurement of phase-change. With objects as large as the *Nebenkern* the measurement of refractive index is unlikely to have been wrong by more than ± 0·004, or 2 per cent of protein.

Table 1

Locust No.	Diameter of *Nebenkern* (μ)	Phase-change (retardation in degrees)	Refractive index	Approx. per cent solid (assuming $\alpha = 0{\cdot}0018$)

Cytology of the Scrophulariaceae and Orobanchaceae

In a previous communication[1], the occurrence of prochromosomes and of size differentiation in the chromosomes of *Rhinanthus minor* Ehrh. were described. Further work has led to the conclusion that the small chromosomes are constant in occurrence and number in *Rhinanthus minor* Ehrh., and that the basic number for the genus *Rhinanthus* is probably $x = 11$. This is the same basic number as the related genus *Euphrasia*, which also possesses a prochromosomal resting nucleus. No evidence of any size differentiation in the chromosome complement of *Euphrasia* exists (P. Yeo, private communication). Other members of the *Rhinanthus minor* aggregate, including *R. borealis* (Sterneck) Marshall, and dwarf plants like *R. perrieri* Chabert (with fuscous spotted corollas) from Shetland, have been found to possess the chromosome number $2n = 22$. Fourteen large chromosomes and a number not yet determined of smaller chromosomes have been observed in *R. calcareus* Wilmott and *R. stenophyllus* (Schur.) Druce. Continental *R. major* Ehrh. has been found to possess chromosomes similar in number and size differentiation to those of the *R. minor* aggregate shown in Fig. 1. Fagerlind[2], in 1936, described the eight smaller chromosomes in the diploid complement of *Alectorolopus* (*Rhinanthus*) *major*, and gave the chromosome number as $n = 11$ for this species.

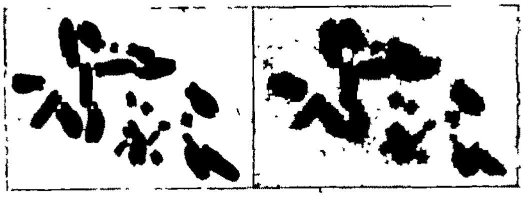

Fig. 1. Root tip chromosomes of *R. minor* Ehrh. at metaphase, showing size differentiation. × 1,500

Melampyrum cristatum L., a species morphologically related to *Rhinanthus* and *Euphrasia* (and like them a hemiparasite), has been examined cytologically. The resting nucleus of this species contains no prochromosomes, the chromatic material being contained in numerous small chromocentres. The diploid number for *M. cristatum* L. is $2n = 18$, which agrees with counts for other members of this genus. The chromosomes at meiosis appear to be of approximately uniform size.

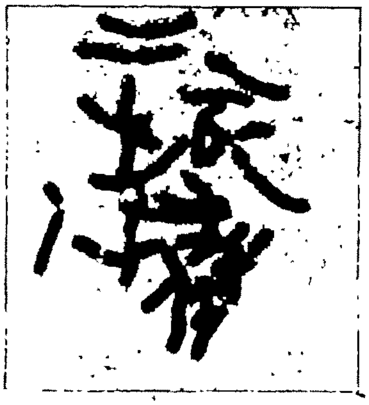

Fig. 2. Mitotic metaphase in the sporogenous tissue of an anther of *Orobanche purpurea* Jacq. The chromosomes are large and the centromeres are distinctly visible at this stage. × 1,500

Note added October 7. *Parentucellia viscosa* (L.) Caruel, formerly known as *Bartsia viscosa* L., another hemiparasitic member of the Scrophulariaceae, has been found to possess $2n = 48$ chromosomes, that is, it has the same basic number $x = 12$ as *Bartsia alpina* L., which is recorded[3] as possessing $2n = 24$ chromosomes.

Species of *Orobanche* in Britain shown to possess $2n = 38$ chromosomes include *O. minor* Sm., *O. maritima* Pugsl., *O. elatior* Sutton., *O. reticulata* Wallr., *O. picridis* F. Schultz, *O. hederae* Duby, *O. rapum-genistae* Thuill and *O. caryophyllacea* Sm. The above species of *Orobanche* are members of the subgenus *Osproleon* Wallr. *O. purpurea* Jacq. from Norfolk has been shown to possess the number $2n = 24$, counts having been obtained in both mitotic (Fig. 2) and meiotic preparations. *O. purpurea* Jacq. has been placed in the subgenus *Trionychon* Wallr., members of which differ from the subgenus *Osproleon* in their possession of two prophylls in addition to each bract. It has now been shown that there are cytological as well as morphological grounds for this division of the genus *Orobanche*.

Systematic Position of the Genus *Oscillospira*

The bacterial nature of the genus *Oscillospira* has been the subject of some dispute; Delaporte[1] considered the group to be Myxophyceae adapted to a parasitic mode of life, which had lost some algal characteristics, and Pringsheim[2] considered it truly bacterial. It has recently been shown to possess typical eubacterial nuclear structures[3]. Pringsheim[2] reported that Robinow had demonstrated flagella, but these structures have not previously been illustrated. It has also proved difficult to demonstrate the existence of true cross-walls between the component cells. These characters constitute one of the most important cytological distinctions between bacteria and Myxophyceae[4].

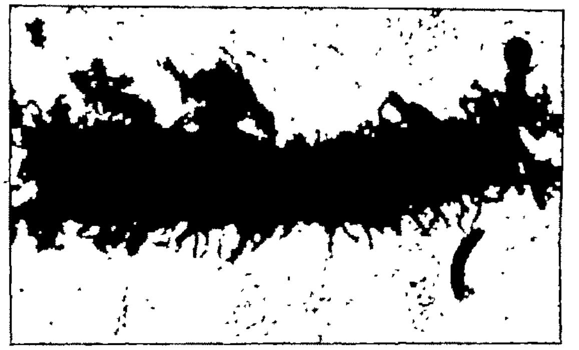

Fig. 1. *Oscillospira guilliermondi*. Kirkpatrick's flagella stain. Preparation made from guinea pig caecal contents, with other micro-organisms adjacent. × 650

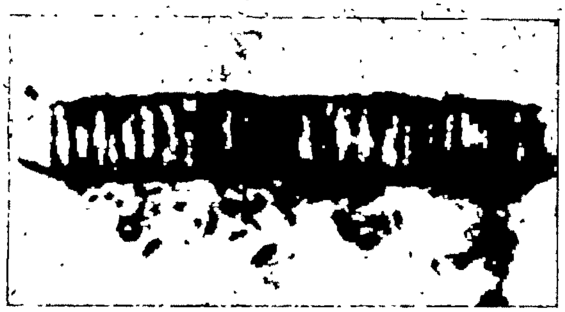

Fig. 2. *O. guilliermondii.* Trichome, consisting of numerous disk-like cells. Cross-walls stained by Hale's method. × 1,000

Both flagella and cross-walls of a distinctly bacterial character have now been demonstrated in *Oscillospira guilliermondii* in the cæcal contents of guinea pigs. Fig. 1 shows a trichome with numerous peritrichous flagella, stained by Kirkpatrick's technique[5]. Fig. 2 shows a similar trichome, in which the cross-walls have been demonstrated by Hale's phosphomolybdic acid–methyl green technique[6].

The demonstration of these structures establishes the eubacterial nature of *Oscillospira* beyond question, despite its relatively enormous size.

I wish to acknowledge the assistance of Miss C. M. F. Hale, who made the preparation shown in Fig. 2.

Antiœstrogenic Potencies of Various Progesterone Derivatives with Oxidation at C_{11}

EVIDENCE has been given that certain antiœstrogenic potencies of progesterone such as the antifibromatogenic, antihysterotrophic and antiluteinizing ones are diminished by oxidation at C_{21}, C_{11} and C_{17}. Thus, deoxycorticosterone (C_{21}—OH) is less antifibromatogenic and less antiluteinizing than progesterone; dehydrocorticosterone, or substance *A* of Kendall (C_{11}=O), is less antifibromatogenic than deoxycorticosterone; 17-hydroxy-deoxycorticosterone, or substance *S* of Reichstein, is neither antifibromatogenic nor antihysterotrophic[1-4]. More recently, the workers of the Upjohn Co. have obtained various derivatives of progesterone by oxidation at C_{11} such as 11-keto-progesterone, 11-α-hydroxyprogesterone and 11-β-hydroxyprogesterone; these compounds, when tested in various ways, have been found to be only about 3–10 per cent as progestational as progesterone, or even less than that[5,6]. Our former knowledge of the diminution of the antifibromatogenic potency through oxidation at C_{11} has been obtained only in comparative work with deoxycorticosterone and dehydrocorticosterone[3]; this is why we thought it convenient to test the three new C_{11}-derivatives of progesterone mentioned as to their antifibromatogenic and antihysterotrophic potencies.

11-*Ketoprogesterone.* All animals had a pellet of œstradiol subcutaneously implanted. The specific steroid to be tested was administered by absorption from one or two pellets containing 40 and 80 per cent of the substance mixed with 60 or 20 per cent of cholesterol; the absorption-rate of pure 11-keto-progesterone was about three times that of progesterone. There was an antifibromatogenic and antihysterotrophic action in all groups as seen when compared with substances VIII–X (see table); but potency was much smaller than with progesterone (IV, V).

11-β-*Hydroxyprogesterone.* Pellets containing 40 and 80 per cent of this substance were used; absorption-rate of the pure substance was almost twice that of progesterone. Activity was very similar to that of 11-keto-progesterone.

11-α-*Hydroxyprogesterone.* The absorption-rate of the pure compound was three times that of progesterone; pellets containing 40 and 80 per cent of the substance were used. There was no antifibromatogenic potency; the fibrous tumoral effect was similar to that of animals receiving œstradiol only. There was a slight antihysterotrophic action. The difference between the two 11-hydroxy-stereoisomers is very remarkable. It may be remembered that a similar situation was found when studying the 17-hydroxy-corticoids: they are all 17-α and lack antifibromatogenic and antihysterotrophic potency[1,2]. The difference between testosterone-17-β and testosterone-17-α (or *cis*testosterone) also is remarkable: the latter showed no antifibromatogenic action with quantities three times those of testosterone[1,3].

Fig. 1 summarizes the comparative results obtained by various workers and also our group in experiments in which steroids with oxidation at C_{21}, C_{11} and C_{17} have been used. Not all the luteoid potencies have been studied so far in a satisfactory manner; a comparative study of the antiluteinizing potency of the C_{11} derivatives of progesterone is in progress.

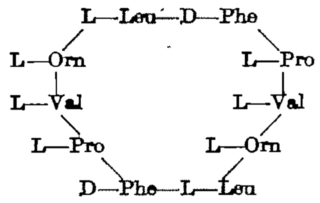
Gramicidin *S*: Relationship of Cyclic Structure to Antibiotic Activity

GRAMICIDIN *S* is a polypeptide antibiotic elaborated by a strain of *Bacillus brevis*[1]. Its postulated structure, well substantiated by experimental results[2], is that of a cyclic decapeptide of the following nature[3]:



The peptide contains a five amino-acid sequence which appears twice. It also contains an amino-acid of the D ('unnatural') configuration, D-phenylalanine, and an amino-acid rarely encountered in naturally occurring peptide structures, L-ornithine.

Harris and Work[4], in order to investigate the structural characteristics of this peptide which might be responsible for its antibacterial activity, synthesized several model non-cyclic peptides and derivatives, including three pentapeptide derivatives having the proper sequence. In one case L-phenylalanine replaced the D-isomer. None of these compounds was found to have more than negligible antibacterial activity. It was concluded that the activity does not seem to be directly related to the presence of D-phenylalanine or L-ornithine but that "the biological activity of gramicidin *S* is intimately related to its cyclic structure". This conclusion is repeated in a review by Bricas and Fromageot[5].

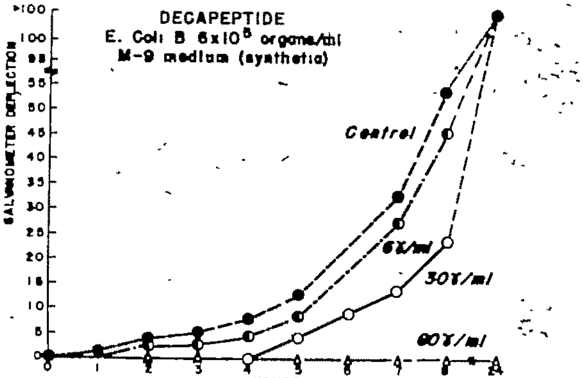


Fig. 1

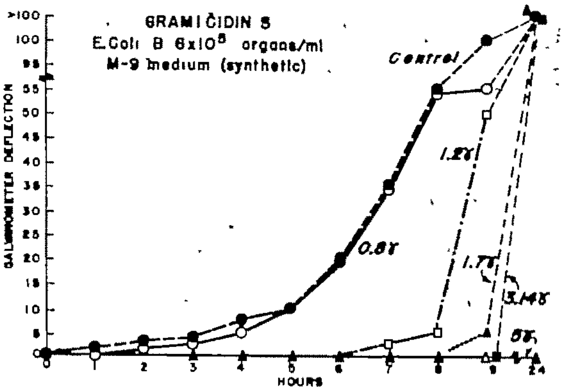

Fig. 2

Erlanger, Sachs and Brand[6] have synthesized, among other related peptides, the straight-chain decapeptides: H. Val – *p*. Tos. Orn – Leu – Phe – Pro – Val – *p*. Tos. Orn – Leu – Phe – Pro. OMe. HCl (L–L–L–D–L)$_2$ and H. Val – Orn – Leu – Phe – Pro – Val – Orn – Leu – Phe – Pro. OH. 3HCl (L–L–L–D–L)$_2$. The latter is identical in structure and sequence with gramicidin *S* except that it is acyclic. The former is, in addition, substituted with a *p*-toluenesulphonyl group on the δ-amino group of each ornithine. The unsubstituted peptide has been found to be biologically active against *Staph. aureus* and *E. coli*. The tosylated compound and other smaller peptides[6] including the pentapeptide H. Val – Orn – Leu – Phe – Pro. OH. 2HCl (L–L–L–D–L) are inactive.

Figs. 1 and 2 compare the antibacterial activity of the decapeptide with that of gramicidin *S* against *E. coli*. In a synthetic medium with an inoculum of 600,000 organisms/ml., the peptide is bactericidal in a concentration of 60 γ/ml. Under identical conditions, 5 γ/ml. of gramicidin *S* gave a similar effect. At lower concentrations both substances increase the length of the lag period. Preliminary work indicates that the surviving organisms possess enzymes capable of destroying or neutralizing the compound. This enzymatic capacity is lost after a single transfer of the organism in fresh medium.

Similar findings were obtained with *Staph. aureus*, the bactericidal concentrations being 3 γ/ml. for gramicidin *S* and 120 γ/ml. for the decapeptide, respectively.

Unless it is assumed that the modes of action of gramicidin *S* and the decapeptide differ, despite their great similarity in structure, one is forced to the conclusion that the cyclic structure is not directly or intimately related to activity. The lack of activity of the pentapeptide rules out the specific influence of D-phenylalanine or L-ornithine, although these amino-acids may be essential to an overall structure possessing activity.

The greater activity of gramicidin *S* may be due to a lesser susceptibility to destruction by bacterial enzymes. A cyclic structure can be attacked only by endopeptidases, and the presence of D-phenylalanine and L-ornithine would materially decrease the number of enzymes capable of hydrolysing this compound. On the other hand, the straight-chain compound is also susceptible to amino- and carboxypeptidases.

Work is continuing with the aim of correlating antibacterial activity more closely with molecular structure.

Intracellular Sites of Metabolism of 3 : 4 Benzpyrene in Mouse Liver

PREVIOUS work[1] has shown that after intravenous injection of colloidal 3 : 4 benzpyrene the bulk of the carcinogen is held in the liver. Excretion takes place over approximately twenty-four hours, the hydrocarbon having undergone metabolic oxidation to one or other of two compounds labelled BpX_1 or BpX_2. These are oxidation products and have been characterized by physical methods and analogy with known derivatives of other polycyclic hydrocarbons as being: 8(OR_1) – 9(OH) – 8,9 dihydro 3 : 4 benzpyrene and 8(OR_1) – 9(OR_2) – 8,9 dihydro benzpyrene respectively. The groups R_1 and R_2 are, at present, unidentified radicals. It has also been found[1,2] that during metabolic oxidation the products derived from 3 : 4 benzpyrene are firmly bound within the tissues where they are formed.

Working upon these facts, we have endeavoured to trace the sites at which oxidation occurs. Groups of 6–8 mice have been injected intravenously with 0·05 mgm. of benzpyrene as a colloid in water. At intervals up to 24 hr. they have been killed, the livers removed, homogenized in Tyrode solution and separated centrifugally into nuclei, mitochondria, microsomes and supernatant. Each fraction has been extracted for benzpyrene metabolites, using the method devised by Weigert[3]. Final purification has been by column chromatography on silica. Estimation of the metabolites was by absorption spectra over the range 340–430 mμ and confirmed by the fluorescence spectra.

Under these conditions the metabolite BpX_2 has been found in all four fractions at time intervals of 2¼, 4, 8, 12, 17 and 24 hr. after injection of the hydrocarbon. Over the same time intervals BpX_1 was only found in the supernatant fraction. Unchanged benzpyrene was regularly found in the nuclear, mitochondria and microsome fractions, but could only be detected in trace amounts in the supernatant fractions.

Since it is possible to argue that the metabolites were adsorbed to the different fractions during the homogenization or centrifuging, a further series of experiments was undertaken. Batches of untreated liver were fractionated as previously and each fraction was then suspended in Tyrode solution containing colloidal benzpyrene. They were placed in the incubator at 37° C. in total darkness, this latter condition being imposed by the necessity for avoiding any photosensitizing action by the hydrocarbon. After periods of up to 2½ hr. incubation, they were extracted as previously and examined for metabolites. BpX_2 was obtained from all four fractions and BpX_1 from the supernatant only. These results show that metabolism must occur within the fractions themselves.

The penetration of benzpyrene into all parts of the cell and its engagement in chemical activity at various sites closely parallels the findings of Danielli[4] and his co-workers with regard to nitrogen mustard. These workers concluded that the action of this compound, which is also carcinogenic, is 'diffuse', and it now appears that benzpyrene behaves in similar fashion.

A detailed account of this work will be published elsewhere.

Nitrogen Fixation by Soil Yeasts

SINCE the discovery by Starkey and De[1] of the soil bacterium *Azotobacter indicum*, which is capable of fixing atmospheric nitrogen under acid conditions, many unsuccessful attempts have been made to isolate this species from acid soils in western Europe. In one such attempt, preliminary experiments had suggested that the soil of a *Betula* – *Calluna* heath in Kent contained organisms able to fix atmospheric nitrogen, but attempts to isolate these organisms by the 'still culture' enrichment method failed. This method is not suited to the isolation of organisms present in acid soil in very small numbers: for such organisms continuous perfusion of a large volume of soil with selective media is a far superior method.

Columns of heath soil (pH 4·5 approx.) taken from the *A*1 horizon of the podsol beneath *Calluna vulgaris* were continuously perfused with media containing a carbon source but no source of fixed nitrogen. On different occasions mannitol, benzoate, various esters and alcohols were used. The perfusate and the soil were sampled at intervals for micro-organisms by streaking on a medium of composition similar to that of the perfusate. Various fungi and bacteria appeared on the plates, particularly on the mannitol plates; on individual transfer to new medium in an atmosphere free from ammonia all failed to grow, with the exception of two yeasts from the mannitol perfusate, which grew slowly but steadily. These two yeasts, one (non-sporing) resembling a *Saccharomyces* and one a pink *Rhodotorula*, were inoculated into nitrogen-free mannitol-phosphate liquid medium and periodically aerated with ammonia-free air; growth was steady and after fourteen days a considerable deposit of yeast had formed. Assessment of nitrogen-content by the micro-Kjeldahl method showed a high gain compared with controls, a gain well above the errors of estimation and corresponding to a rate of fixation (on different occasions) of up to 4 mgm. nitrogen per gm. of mannitol originally available. An interesting feature of these nitrogen-starved yeasts was the presence of large oil globules in the cells and a very sparse retention of dye when stained by Gram's method.

In the course of further extensive investigations by Chayen, using perfusion enrichment followed by isolation on nitrogen-free media, a large number of yeasts have been isolated from the *A*1 horizon of the same *Calluna* heath soil. A representative sample of these was tested for ability to grow in aerated nitrogen-free media under conditions ensuring the rigid exclusion of atmospheric ammonia; some twenty isolates grew under these conditions. Tests for increase in fixed nitrogen by micro-Kjeldahl estimation on the whole culture gave significant gains; for one *Rhodotorula* these gains corresponded to the fixation of 1–3 mgm. of atmospheric nitrogen per gm. of glucose available. Further tests on this *Rhodotorula* and on another isolate, using an isotopic nitrogen technique, are described in the following communication by Roberts and Wilson.

In addition to the nitrogen-fixing yeasts, two quite distinct strains of nitrogen-fixing bacteria of the genus *Azotobacter* have been isolated using mannitol as the perfusate. These bacteria are distinct from previously described 'species' of *Azotobacter*, including *A. indicum*. This work, with descriptions of the organisms and their growth under differing experimental conditions, will be published in detail elsewhere.

[1] Starkey, R. L., and De, P. K., *Soil Sci.*, 47, 329 (1939).

A METHOD has been developed in this laboratory whereby the rate-constant of the nitrogen-fixation process is obtained solely from isotope abundance measurements[1]. At the suggestion of Metcalfe and Chayen, we have applied this method to certain soil yeasts isolated by Chayen and have confirmed their observations that these organisms are capable of taking up molecular nitrogen (see preceding communication).

Cultures of two yeasts, *Rhodotorula* (I) and *Saccharomyces* (II), were studied; they were thought to have nitrogen-fixing capacities 1/10 and 1/50, respectively, of that of *Azotobacter*. An atmosphere consisting of oxygen, argon and nitrogen, the latter containing 32·0 atom per cent excess of nitrogen-15, was circulated through duplicate cultures of the yeasts in a medium free from combined nitrogen. The cells were actively budding immediately prior to the experiment. At the end of four hours, the cells were harvested, subjected to Kjeldahl digestion, and the ammonia produced converted to nitrogen by reaction with sodium hypobromite. The isotope abundance in these samples was determined by means of a mass spectrometer; the abundance of nitrogen-15 in ordinary air was 0·41 per cent.

Culture	Atmosphere			Percentage nitrogen-15 in cell nitrogen	
	p_{N_2}	p_{O_2}	p_A	(i)	(ii)
I	0·17	0·40	0·30	1·38	1·41
II	0·04	0·40	0·40	0·45	0·48

These results show clearly that the yeasts, especially I, had taken up molecular nitrogen. Moreover, the extent to which fixation occurred was consistent with expectations based on total nitrogen determinations.

We are indebted to the Royal Society for a grant with which the isotopic nitrogen used in this experiment was purchased, and to Dr. G. A. Meek, who performed the isotope analyses. One of us (T. G. G. W.) is indebted to the Middlesex Education Committee, and to Glaxo, Ltd., for financial assistance.

Acceleration of Flowering in Non-vernalized Chrysanthemums by the Removal of Apical Sections of the Stem

IT has been shown that plants of *Chrysanthemum morifolium* 'Sunbeam' (incorrectly termed 'Indian Summer'), raised from basal cuttings taken from parent plants grown and flowered at high temperatures, require a period of low temperature or vernalization in order that normal stem elongation and rapid flowering may occur. Without such a period of low temperature these plants grown in high temperature conditions (> 60° F.) fail to elongate normally and are considerably delayed in flowering[1].

If an apical section of the stem is removed, however, the two or three lateral shoots thus induced to develop do not show the rosette habit and diageotropic growth characteristic of the main axis, and flower rapidly (see Fig. 1).

Non-vernalized plants of 'Sunbeam', from cuttings taken on December 30, 1953, were grown at temperatures above 60° F. in natural day-length conditions until June 15, 1954. On this date the plants, which had laid down approximately fifty leaves, were cut back to twenty-five, thirty-five or forty-five leaves, or left intact, and were placed immediately in short-day (10-hour) conditions. The laterals, which developed as a result of removal of the apical sections, elongated normally and rapidly produced macroscopically visible buds. The main axis of the intact

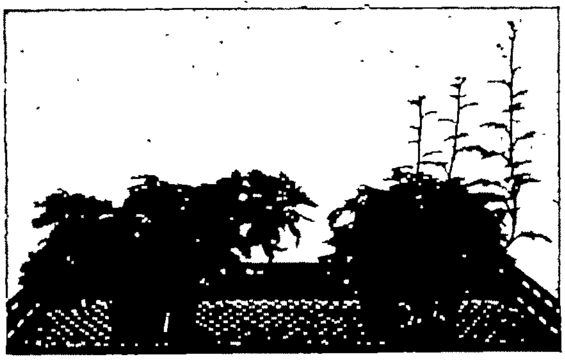

Fig. 1. Non-vernalized plants of 'Sunbeam' after seven weeks of short-day conditions. Left, intact plant; right, plant cut back to 25 leaves

plants continued to show rosetting and diageotropic growth, and flowered only after a considerable delay. The acceleration of flowering is shown by the decreased number of weeks to bud (from the date of commencement of the short-day treatment) of the distal lateral of the cut-back plants compared with the terminal bud of the main axis of the intact plants (Table 1). The number of leaves laid down on the terminal laterals of the cut-back plants and the approximate number of leaves laid down on the main axis of the intact plants, from the commencement of the short-day treatment to flowering, is also shown in Table 1. The increase in internode elongation of the lateral shoots is also apparent.

Removal of apical sections from non-vernalized plants of 'Sunbeam' resulted, therefore, in accelerated flowering and normal elongation of the internodes on the distal lateral shoots when the plants were grown in short-day, high-temperature conditions, and apparently removed the source of some substance normally inhibiting flowering and internode elongation in such non-vernalized plants. The production of a single inhibiting substance by the vegetative apex of non-vernalized plants preventing both internode elongation and flowering would appear to be too simple a hypothesis; but it seems likely from these results that, in this variety, some inhibiting substance is produced by the apex of the main axis which is not produced, or produced to a lesser degree, by the apices of the lateral shoots which develop when apical dominance is removed.

Another variety, 'President', which entirely fails to flower when not vernalized and shows extreme rosetting[2], did not show the same response to removal of an apical section of the stem. A slight increase in elongation of the internodes of the lateral shoots was observed initially, but afterwards the rosetted habit was resumed and the lateral shoots failed to flower except in two instances (16·5 per cent of the plants). In no case did plants flower on the main axis. In this variety, which shows a more extreme type of behaviour (rosetting and failure to flower) in the non-vernalized condition, the inhibiting effect is apparently re-imposed in the lateral shoots when the apical sections are removed in short-day conditions. Evidence from a further experiment, as yet incomplete, suggests that if a sufficient number of long-day cycles is given after decapitation, the inhibition is not completely re-imposed and some lateral shoots are able to elongate, and will afterwards flower when placed in short-day conditions. These experiments will be reported in more detail elsewhere.

Table 1. EFFECT OF REMOVAL OF APICAL SECTIONS OF THE STEM ON FLOWERING AND INTERNODE ELONGATION IN *Chrysanthemum morifolium* 'SUNBEAM'

	Intact plants*	Cut back* to leaf No. 25	35	45	L.S.D. at $P = 0·05$

Occurrence of *Haplosporangium parvum* in the Lungs of the Mole (*Talpa europaea*)

DURING the spring of 1947 and again in 1953, large numbers of dead and dying moles were found on the Berkshire Downs, and examination (by A. McD.) of many of these and of others trapped at the same time showed evidence of pneumonia. Lesions of a granulomatous nature, varying greatly in size, were scattered throughout the lungs, often protruding above the surface, and histological examination showed these reactions to be invariably associated with the presence of a central thick-walled spherule, 100–200 microns in diameter (Fig. 1). Material from these animals was examined in the course of a survey of animal mycoses sponsored by the Agricultural Research Council, and the spherules were recognized as bearing a close resemblance to those found in *Haplosporangium parvum* Emmons and Ashburn infection in small mammals, hitherto only reported from North America by Emmons and Ashburn[1] and Dowding[2].

Fresh material from the Berkshire epizootic not being available, a number of moles trapped in the Exeter district were examined (by P. K. C. A.) during May 1954, through the kind co-operation of the Devon Agricultural Executive Committee, and, from lesions similar to those described above, typical *Haplosporangium parvum* was isolated in culture. Of thirty-one apparently healthy moles from Devon and

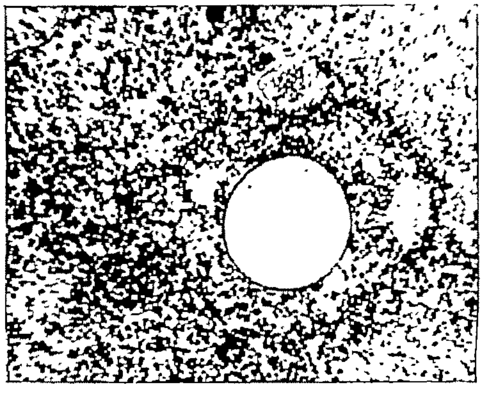

Fig. 1. Section of mole lung showing thick-walled spherule. × 100

Berkshire, twenty-five had spherules present in varying numbers in the lungs. The isolate has the 'granular type' of colony described by Carmichael[3], forms conidia 3–4 microns in diameter and, with a spherule diameter of 100–390 microns, agrees well with the northern strain of the fungus (Dowding[2]). This appears to be both a new host species and the first record for Europe, although we believe *H. parvum* is now known in several other parts of the world.

The role, if any, of *Haplosporangium parvum* in the periodic fluctuations in the mole population of Britain, which occur about every six years (cf. Elton[4]), is undoubtedly complicated by the additional presence in those lungs we have examined of a nematode (species not yet identified), and at least one pathogenic aerobic actinomycete (*Nocardia* sp.). The significance of these organisms, especially in apparently healthy animals, is in no way understood.

Herbarium specimens and cultures have been deposited at the Mycological Reference Laboratory, London School of Hygiene and Tropical Medicine, and at the National Microbiological Institute, Bethesda, Maryland.

Transmigration of Unborn Mice

The evidence on transuterine ('internal') migration, that is, the passage of ova down the oviduct and uterine horn of one side into the uterine horn of the other side, has recently been summarized by Boyd and Hamilton[1]. They found no record of the phenomenon in any rodent on which relevant observations had been made (rabbit, guinea pig, rat and field vole). Young[2] has, however, since demonstrated its occurrence in the rat.

In the course of fertilized egg transfers, we have found that transuterine migration of fertilized eggs can also occur in mice. Fertilized eggs were collected from immature albino females, $2\frac{1}{2}$ or $3\frac{1}{2}$ days after they had been artificially induced to ovulate[3] and mated to albino males. The eggs were injected by the method of Fekete and Little[4] into the upper part of the left uterine horn of adult females mated $2\frac{1}{2}$ or $3\frac{1}{2}$ days previously. Shortly before term, the recipients were killed and the contents of their uteri examined. Since the recipients and their mates were homozygous for full colour, embryos derived from transferred eggs could be distinguished from the native embryos by eye colour.

Of twelve embryos derived so far from eggs transferred $2\frac{1}{2}$ days after ovulation, one was found implanted in the right (uninjected) horn. Of thirty-four derived from eggs transferred at the $3\frac{1}{2}$-day stage, three were found in the right horn.

It is possible that the phenomenon does not occur in normal pregnancies, and that these transmigrations were assisted by the pressure of the fluid medium in which the eggs were injected. Conclusive evidence would be provided by the injection of unfertilized eggs into the *bursa ovarii* and their fertilization in the host animal. By the time that such eggs arrived in the uterus, the hydrostatic condition of the two sides of the reproductive tract would surely have become equalized. An experiment of the required type was recently performed by Runner and Palm[3]. Of twenty embryos derived from transferred eggs, none was found implanted on the uninjected side. But the numbers involved are small and there is no significant discrepancy between this result and our own.

We are in receipt of a research grant from the Agricultural Research Council, which we gratefully acknowledge.

Morphological Basis of Quality in Tea

The possibility of distinguishing morphological characteristics that will help in the recognition of strains of tea capable of producing enhanced quality in the manufactured product is of importance to tea producers and research workers in regions outside Assam. The pioneer work of Dr. W. Wight and Mr. P. K. Barua[1] is consequently of particular interest.

While recognizing that such work is only in a preliminary stage, there appears to be some confusion in the interpretation of the data between the concepts of the statistical significance and importance respectively to be attached to the values of the correlation coefficients under consideration.

The high significance of the correlation between pigmented plants and hairy plants indicates that the value of 0·493 has not arisen fortuitously; but it gives no indication of the importance of the value itself as a measure of association. The correlation coefficient is not equally sensitive throughout its range to differences in degree of association, relatively small variations in value in the high range being of more importance than much greater ones at the other end of the scale.

A more sensitive estimate of predictability can be derived from the function $1 - \sqrt{1 - r^2}$. For a correlation coefficient of 0·493 the predictability index is 0·13. The analogous figure for the correlation coefficient of 0·76 between taster's valuation and leaf hairiness is 0·35.

While the possibility of concentrating 35 per cent of the total variation in a common association with a single morphological characteristic is suggestive, it scarcely merits the statement that "hair can be taken as a reliable index of quality".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer (with a degree in agriculture or equivalent qualification, and with sound experience in practical work) in Agriculture, at the Cumberland and Westmorland Farm School, Newton Rigg, near Penrith—The Director of Education, 5 Portland Square, Carlisle (November 3).

Lecturer (preferably with experience in soil mechanics and geology) in Engineering, at Constantine Technical College, Middlesbrough—The Director of Education, Middlesbrough Education Committee, Woodlands Road, Middlesbrough (November 3).

Lecturer (woman) in Biology, at Manchester Training College—The Chief Education Officer (83/L), P.O. Box 480, Education Offices, Manchester (November 4).

Assistant, Grade A (with graduate or equivalent qualifications), at the College of Commerce and Technology, Sheffield, to teach physics in national certificate courses in chemistry and metallurgy, in advanced level classes for the general certificate of education, and in various City and Guilds courses—The Director of Education, P.O. Box 67, Leopold Street, Sheffield 1 (November 6).

Scientific Officer or Senior Scientific Officer (qualified bacteriologist or chemist with sound bacteriological training) for work on disinfection involving a study of chemical sterilizers, including methods of laboratory evaluation—The Secretary, National Institute for Research in Dairying, Shinfield, near Reading, quoting 54/6 (November 6).

Technician (preferably with photographic experience) in the Zoology Department—The Registrar, University College of Wales, Aberystwyth (November 6).

Research Student (with the B.Sc. (Special Chemistry) degree of the University of London) in Chemistry—The Principal, Brighton Technical College, Brighton (November 8).

Lecturer (with a degree and/or other recognized professional qualification, and advanced knowledge of some branch of thermodynamics or gas dynamics, and of the theory and performance of propulsion units, and some practical experience of one or more modern propulsion systems) in the Department of Aircraft Propulsion—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks (November 12).

Demonstrator (with special qualifications and interests in mineralogy and petrology) in the Geology Department—The Registrar, University College of North Staffordshire, Keele, Staffs (November 13).

Assistant (preferably with qualifications in ecology or mycology) in Botany—Joint Clerk to the University Court, Queen's College, Dundee (November 15).

Head of the Department of Agriculture, Senior Lecturer in Tropical Agriculture, Lecturer (Grade A) in Animal Husbandry, Lecturer (Grade B) in Horticulture, Lecturer (Grade B) in Workshop Practice (Agricultural), and Farm Manager, at the Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (November 15).

Coal Survey Officer (with a good honours degree or equivalent in a science subject, preferably with a sound background in geology and chemistry), in the Ayrshire Coalfield of Scotland, for work which will involve a detailed study of the structure and physical and chemical properties of the coal seams of the area—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/860 (November 16).

Lecturer in Chemistry—The Principal, University College, Galway, Ireland (November 19).

Lecturer in Anatomy and Histology—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (November 20).

Lecturer (preferably with palæontological research and field experience) in Geology, at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, November 19).

Lecturer in the Department of Pathology—The Registrar, The University, Leeds 2 (November 20).

Physicist, Biophysicist or Physical Chemist, Senior Research Officer or Research Officer grade (with a university honours degree in science with physics or chemistry as a major subject, or equivalent qualifications) in the Biochemistry Unit, Wool Textile Research Laboratories, Commonwealth Scientific and Industrial Research Organization, Parkville, Melbourne, Victoria, to participate in an extensive research programme concerned with the structure of fibrous proteins, polypeptides and related compounds by X-ray, infra-red and optical techniques—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 462/51 (November 20).

UNIVERSITY LECTURER (preferably with veterinary or medical qualifications) IN THE DEPARTMENT OF ANIMAL PATHOLOGY, to undertake teaching and research in metabolic and nutritional diseases—The Secretary, Appointments Committee of the Faculty of Biology "B", Department of Pathology, University of Cambridge, Tennis Court Road, Cambridge (November 20).

BRITISH INSULATED CALLENDER'S CABLES LTD RESEARCH STUDENT (with a good honours degree in engineering or physics), for research into the mechanical properties of powdered materials in relation to their use as electrical insulators—The Registrar, King's College (University of London), Strand, London, W.C.2 (November 22).

ANALYST IN THE DEPARTMENT OF AGRICULTURE to participate in a special research project—The Registrar, The University, Leeds 2 (November 30).

CHAIR OF AIRCRAFT ELECTRICAL AND ELECTRONIC ENGINEERING—The Principal, College of Aeronautics, Cranfield, Bletchley, Bucks (November 30).

SENIOR LECTURER IN ORGANIC CHEMISTRY, and a SENIOR LECTURER (preferably with primary interest and experience in either the theory of machines or machine design) IN MECHANICAL ENGINEERING, at the University of Adelaide, Adelaide, South Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (November 30).

PROFESSOR OF PHYSICS at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 1).

CHAIR OF GLASS TECHNOLOGY—The Registrar, The University, Sheffield 10 (December 11).

BIOMETRICIAN for duties which include the design of experiments in all phases of tobacco production, together with the analysis of data and related statistical practice—The Director, Tobacco Research Board of Southern Rhodesia, P.O. Box 1909, Salisbury, Southern Rhodesia (December 31).

DIRECTOR (with high scientific attainments, preferably in fields related to soils or crops, combined with administrative experience involved in the organization and running of a research institute or university department, and preferably with experience of tropical conditions) OF THE EAST AFRICAN AGRICULTURE AND FORESTRY RESEARCH ORGANIZATION, Muguga, near Nairobi, Kenya—The Director of Recruitment (H.M. Overseas Civil Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.196/161/02 (December 31).

MEDICAL RESEARCH FELLOW (medical graduate with some experience and success in research), for investigations in some aspect of virology, bacteriology, hæmatology or histopathology—The Director, Institute of Medical and Veterinary Science, P.O. Box 14, Rundle Street, Adelaide, South Australia (December 31).

ASSISTANT LECTURER IN (Agricultural) ENGINEERING—The Principal, Shuttleworth College, Old Warden Park, Beds.

BRADFORD DYERS' ASSOCIATION RESEARCH FELLOW (with high qualifications in science), to undertake research in tinctorial chemistry, textile chemistry or an allied subject—The Principal, Technical College, Bradford 7.

ENGINEERS, CHEMICAL ENGINEERS or PHYSICISTS (with a good university degree, and preferably with industrial experience), for training as Reactor Technologists—The United Kingdom Atomic Energy Authority, Industrial Group Headquarters, P.O. Box 19, Risley, Warrington, Lancs, quoting 694.

GRADUATE CHEMIST as technical assistant in the Patents Division—The Secretary, National Research Development Corporation, 1 Tilney Street, London, W.1.

HORTICULTURIST (with a degree in horticulture or equivalent, and a working knowledge of fruit and vegetable crops, and preferably with experience of the marketing of perishable vegetable crops), to take charge of the Horticulture Section of the Department of Agriculture, Cyprus—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.63/17/05.

LIBRARIAN AND INFORMATION OFFICER (graduate with library qualifications and experience)—The Director, Scott Polar Research Institute, Cambridge.

RADIO ENGINEER (with experience of high-power broadcasting transmitting equipment, and preferably with an engineering degree or other professional qualification), to be responsible for the operation and maintenance of the 20 kW. and 1 25 kW. transmitters, and two 250-Watt R.C.A. transmitters of the Dar es Salaam Broadcasting Station—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.178/8/05.

REGIONAL TRIALS OFFICER (with a degree in botany or agriculture or equivalent qualification, with practical experience in crop production)—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

SENIOR SCIENTIFIC OFFICER (Operational Research) (with a first- or second-class honours degree in mathematics or physics or equivalent qualifications, and with at least three years postgraduate experience of industrial operational research), with the U.K. Atomic Energy Authority, Risley, to assist and advise operational research groups in the laboratories, particularly on the use of mathematical, especially statistical, methods, and to collaborate with these groups when their investigations cover fields outside the immediate scope of the work of their laboratories—The United Kingdom Atomic Energy Authority, Industrial Group Headquarters, P.O. Box 19, Risley, Warrington, quoting 693.

TEA OFFICER (with a wide experience of all aspects of tea growing and manufacture under commercial conditions, and a thorough knowledge of the marketing of tea) in Mauritius, to implement plans for developing the tea industry, to advise planters and manufacturers on improved methods of production, and to take charge of the Tea Experiment Station and of any other Government plantations, and a Government Tea Factory, if and when constructed—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.63/52/05.

SCIENCE AND THE PRESS

THE growth of interest in the presentation of science in the Press during the past four or five years is noteworthy. The Royal Society Scientific Information Conference in 1948 stimulated a keener interest in the presentation of science to scientists; thus, for example, there was a discussion on the presentation of technical information at the Birmingham meeting of the British Association in September 1950, various scientific and learned societies have issued fuller guidance for the writers of papers presented to them for publication, and the Presentation of Technical Information Discussion Group has been formed as a sequel to Prof. R. O. Kapp's lectures on the subject at University College, London. Interest in this aspect has been recently quickened by the stress laid on the importance of effective communication in order that the utilization of the results of research by industry may be expedited.

Here, however, we are concerned also with the second aspect of the subject—the presentation of science to the public. Discussion of this aspect has tended to centre in Great Britain around the function of the British Association and the manner in which the annual meeting of that Association could best facilitate the exposition or interpretation of science to the non-specialist—if not indeed to the general public. It is increasingly manifest that the use made of scientific advances, and ultimately the continuance of adequate support for scientific research, depend upon the existence of a climate of opinion which understands sufficiently the nature of scientific work and the conditions under which it is most fruitfully carried out. It is also becoming recognized that there are widespread fears about science and the effect of its activities, springing essentially from ignorance, and that the persistence of that ignorance may affect the future of science itself.

Several papers in the *New Zealand Science Review*, published by the New Zealand Association of Scientific Workers, discussed three years ago these questions, particularly the improvement of presentation of scientific papers and the relations between science and the Press; and a long article by Prof. I. B. Cohen in *Impact of Science on Society* in the summer of 1952 discussed the education of the public in science, considering, however, the general educational aspect, rather than the appropriateness or effectiveness of the particular vehicles—the written word, radio or television—by which that education is to be achieved. Early this year in his Clayton Memorial Lecture, "The Public Influence of Broadcasting and the Press", Sir William Haley, commenting on the more enduring effect of the printed word compared with the spoken word, indicated the supreme importance of the Press if it set out to use its opportunities for influencing and improving public understanding.

Those opportunities and the whole technique of presentation in the Press have been discussed more fully in two recent papers, both entitled "Science and the Press". The first of these, which was delivered by Mr. L. J. F. Brimble before the Royal

Society of Edinburgh on January 11, received wide publicity at the time and has now been published. The second, by Mr. W. E. Dick, editor of *Discovery*, appears in *Impact* of September (Unesco, 19 Avenue Kléber, Paris, 16), and discusses further some of the points raised by Mr. Brimble as well as reviewing the part which the printed word has played in the development of science itself.

It is one of the merits of Mr. Dick's article that he puts the relations of science and the Press in their historic perspective. He does not over-stress the importance of the printed word as a means of communicating scientific knowledge, as is sometimes done by protagonists of mechanical devices for recording, classifying, filing and disseminating scientific and technical information. Even to-day, personal contact and discussion have a value not merely in stimulating thought and the flow of ideas but equally in the exchange of the residual information which is liable to be missed by abstracting and indexing systems.

This factor deserves more weight than it often receives in considering how far it is worth while extending the field of an abstracting system, and it is worth stressing here because the relations between science and the Press are best discussed on such a practical basis and not in terms of theory. They will, in fact, vary according to the conditions of the period under consideration and the influence of other means of communicating knowledge. Both, however, are, as Mr. Dick reminds us, intimately concerned with the freedom of the Press, and if the struggle for a free Press was waged by men of letters rather than by the scientists, it is on the latter that the onus lies for defending that freedom against encroachment to-day.

Mr. Dick points out that the establishment of writing as a professional activity of the first importance dates from the French Encyclopædia of the early eighteenth century. From that time the Press has been indeed a Fourth Estate, able to contribute its full share to the advancement of knowledge, whether in science or in other fields. Scientific periodicals soon became the main method of communicating the results of research and the indispensable tools of the scientific worker, though societies like the Royal Society for the Encouragement of Arts, Manufactures and Commerce, the Lunar Society, the Manchester Literary and Philosophical Society and the Royal Institution also forged links between industry and science in Britain. By the beginning of the nineteenth century, daily newspapers were well established and there were also some vigorous periodicals. Journalists with a good sense of what interested the public began to record events in the world of science, and this tendency was encouraged by the formation of various associations aimed at strengthening the ties between the world of science and the general public, such as the Deutsche Naturforscher-Versammlung and the British Association for the Advancement of Science.

These associations recognized that the help of the Press was indispensable for the purpose just indicated; but they also aimed at providing a common meeting ground for all scientific specialists. This function has steadily increased in importance with the growing fragmentation of science, and in recent years particularly, the mounting costs of publication have set limits to the economic production of highly specialized periodicals with only a restricted circulation; indeed, the cost of publication of its journal may to-day absorb as much as thirty per cent of the annual income of a scientific or technological society.

This position, and the difficulty of securing effective coverage of such literature by abstracting bureaux, have led to suggestions that the scientific paper is no longer the most appropriate means of recording and disseminating scientific knowledge. Mr. Dick comments, however, that any attempt to rationalize scientific publication would involve one great danger that the multiplicity of periodicals has practically eliminated. When there were only a few scientific periodicals, some first-class scientists, such as Joule and F. W. Lanchester, found great difficulty in getting novel work published. There is always a distinct risk that the most conscientious editor or editorial board will fail to recognize the true value of a paper in the Joule or Mendel class. It is rightly maintained that the advantage to the truly original scientific thinkers of a rich variety of periodicals to which they can submit their work offsets the embarrassment to searchers of the literature caused by such variety.

If, however, we are to indulge in such variety, it is essential that, as both Mr. Brimble and Mr. Dick insist, we should give more attention to the preparation and presentation of scientific and technical papers themselves. Even a genius may fairly be expected to take some care that prolixity and careless writing do not increase what may well be the inherent difficulty of following an original and unfamiliar idea. "Slovenly writing", wrote Bishop H. H. Henson, "is nothing but bad manners in composition", and though that precept might be heeded above all by the scientist who attempts to expound his results to the general public, it equally applies in the presentation of his work to his fellows, whether specialist in his own field or not. Mr. Brimble strongly deprecates the tendency to rush into print and, without discussing the controversial question of the most appropriate means and place for the publication of detailed research results, it may be asserted that the length of most scientific and technical papers would probably be reduced and their clarity and value enhanced if, as he suggests, before submitting a communication, every scientist satisfied himself that he had said what he wanted to say, and in the minimum number of words, and that it was worth saying at all.

Quite apart from the saving of space, the improvement in quality resulting from such general practice could be most important. "Wherever," wrote George Stuart Gordon, in "Anglo-American Literary Relations", "a man has fairly set down the best that he knows about the thing he knows best, and in words that tell his meaning, there, always, will be literature." To the extent to which the specialist achieves that ideal, he will solve, by and large, the problem of communication, whether to his fellow scientists or to his fellow citizens in general.

The operative clause is "in words that tell his meaning", and its significance is well illustrated by Mr. Dick's reference to Charles Darwin's "On the Origin of Species". It was written as a scientific treatise for Darwin's fellow scientists, but reached a far bigger public than either author or publisher foresaw. Darwin made no concession to popular appeal beyond lucidity of thought and of expression, and his success with this one book may be fairly attributed to his plain, unpretentious but most lucid style. There is thus a tradition of good writing among British scientists which may well make us hesitate to accept the pronouncement that the study of modern science destroys the ability to write good English. Weakness in this respect may well arise, not so much from the study of science, as from defects in education: it is not the scientist alone who mars his exposition by jargon. The tendency is widespread and deeply embedded, despite onslaughts ranging from those of Sir Arthur Quiller-Couch to Sir Winston Churchill. None the less, the use of jargon has dangers, as both Mr. Dick and Mr. Brimble emphasize, and the success of the "Origin of Species" as a best-seller far beyond the confines of the scientific world is a striking demonstration of the fallacy that a scientist is bound to rely on jargon. The book contained a new theory of evolution, the main points of which were not easy to grasp, and it was packed with unfamiliar details. Everyone, however, with any pretensions to being cultured read it, and many thoroughly grasped the main points of Darwin's theory.

In the face of this and other instances, it cannot be maintained even to-day that the important concepts of science are beyond ordinary comprehension. The task of communication, however, demands a greater effort at clarification than the scientist frequently troubles to make; but unless he makes that effort his work cannot be expounded or interpreted even to his fellow scientists. Still less can the task of explanation to the general public be carried out by himself or anyone else. As Dr. Barbara Wootton recently remarked, in her presidential address to the annual conference of Aslib, efficient communication, in the social sciences or in any other field, is only possible on the basis of common experience, and it is not only in the social sciences that the use of jargon introduces pitfalls. Jargon is peculiarly liable to cause the confusion to which Dr. Wootton refers. Such words tend to bear one meaning to the scientist and another meaning—possibly several different meanings—to other scientists or to non-scientists, and serious misunderstandings arise even in the physical sciences, where there is less risk than in the social sciences of discussions about words being confused with discussions about the things which the words are supposed to represent.

From the point of view of communication, however, the use of jargon should be eschewed because of the way in which it contributes to the emotional entanglements which Dr. Wootton rightly characterizes as the most serious consequence. That is also the main reason why, though the interpretation and exposition of science to the general public must be carried out by co-operation and understanding between scientists and the Press, the major responsibility for it must lie on the scientist. However much they may value and seek the co-operation of the Press, scientists to-day have a public duty to see that their work is clearly explained at the appropriate stage to the public.

As Mr. Dick remarks, the public is entitled to a reasonable amount of information about all researches supported from public funds, and it is now better appreciated that the presentation of such information has a close bearing on its utilization for some practical purpose in industry. Even for independent or privately financed research, a reasonable degree of publicity is desirable from the point of view of science itself, as Prof. Kirtley Mather has indicated. Publication for the non-scientist is an issue of public importance and can vitally affect the advance of science itself. It can no longer be regarded as a matter of privilege to be granted as, when and if the scientist so decides. What is the appropriate stage may be a matter of judgment, and of discussion; but it should no longer be an arbitrary decision.

Both Mr. Brimble and Mr. Dick in these two papers have much to say that is helpful to the scientist and to the Press in regard to this task of popular exposition and interpretation. Mr. Brimble stresses, for example, the importance of the scientist being readier to co-operate and more accessible to the Press; and part at least of the value of both papers lies in the extent to which they should remove some causes of misunderstanding and friction. Mr. Brimble, for example, paid a generous tribute to the improvement, almost out of all recognition, of British newspapers, by and large, in their presentation of scientific news and their interpretation of scientific discovery, and to the intellectual leadership in the ordinary newspaper; the Press is still the most effective moulder of public opinion, and sound opinions must be based on knowledge of the facts. This tribute gives the greater force to his criticism of some general failings, which sometimes hinder men of science from co-operating as freely as they might otherwise do. Chief of these failings is the lack of appreciation that the very essence of science is accuracy, and that the checking and counter-checking necessitated thereby make it very rare for science to give what can be described as 'hot' news. The same point is made by Mr. Dick, who remarks that there is room for compromise here. Both papers should at least help scientists to realize the relatively low proportion of erroneous reports which appear in a daily newspaper, in spite of the pace at which the collection and publication of news proceeds. A sense of proportion, above all in regard to details, should go far to facilitate harmonious working.

While that suggestion applies particularly to the scientist, the question of factual accuracy is one which concerns scientist and journalist equally. If the Press takes to heart Mr. Brimble's second major criticism, and is readier to admit and correct an error when under no legal pressure, much would be done to establish the conditions of confidence and mutual respect essential for effective co-operation. A reputation for accuracy depends at least in part on the readiness to acknowledge and correct inadvertent slips or errors. Such a reputation is a priceless asset which once lost is hard indeed to regain. There is an aside on the Press in Dr. R. M. Hutchins's brilliant little book, "The University of Utopia", on which a journalist might well reflect in this connexion. The Utopians, writes Dr. Hutchins, are a people trained to criticism, and since the blandishment of propagandists and advertising men would leave them unmoved, there is no point in indulging in it and there were no propagandists or advertising men in that happy country.

A third criticism made by Mr. Brimble also bears very closely on the vital question of the public relations of science and the maintenance of full freedom of investigation and communication with which both press-men and scientist are so closely concerned. He deprecates the tendency to expect leading men of science to commit themselves, immediately a new scientific discovery of paramount importance is made, to opinions concerning its human implications. Prematurely to do so is liable to impair rather than to improve and restore the public confidence upon which the continuance of public support of science ultimately depends.

Such reasons as these therefore demand much greater attention to this task of exposition and interpretation by scientists in general, and it is to be hoped that the misappropriation of the word 'communication' into a narrow technical field which Dr. Wootton deservedly castigated will not impede progress in this wide task of improving the communication of scientific knowledge to the world in general. Such misappropriation is perhaps particularly liable to hinder that more generous attitude to the scientific expositor which has been urged in these columns for many years. As Mr. Brimble remarked, it is very important that the expositors and interpreters of science as represented by science writers should be sure of the appreciation and support of their professional colleagues to which they are entitled.

When all that is possible has been done to improve the relations and co-operation between scientist and the Press, a large share of the responsibility for the interpretation and exposition of scientific discovery to the general public must rest upon such professional science writers. Some may be scientists, specially gifted as expositors or interpreters; some may be journalists by training, with special interest in or understanding of science or some branch of science; but from whatever side they have approached it, their position is essentially the same, and their success depends on a clear understanding of the public they are attempting to reach, the limitations of that public, and of the subject they are to expound. Only on that basis can their ability to assess values, and to interpret facts in language understood by all, make any real contribution to the public understanding of science. That task demands in its exercise the same qualities of mind and unswerving loyalty to truth as are demanded in laboratory or field investigations; nor can we expect men and women of the calibre which exposition and interpretation, as distinct from propaganda, demand to come forward in the numbers needed, unless their fellow scientists accord them the honour and respect they deserve and co-operate whole-heartedly with them in that task.

FREEZING AND DRYING BIOLOGICAL MATERIAL

Biological Applications of Freezing and Drying
Edited by R. J. C. Harris. Pp. xii+415. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1954.) 10 dollars.

FREEZING and freeze-drying are two techniques the practical development of which would have been impossible without advances in refrigeration technology. While extreme low temperatures can only be attained by liquefied gases, the relatively easy maintenance of 'deep-freeze' temperatures has made possible the preservation of delicate material such as spermatozoa and blood corpuscles. But low temperatures introduce new problems, particularly those of thermal and osmotic shock: because slow cooling reduces osmotic shock at low temperatures, especially in the presence of glycerol, most living cells survive slow cooling better than rapid or ultra-rapid freezing. Where survival of cells is unimportant, as in tissue sections or preparations for electron microscopy, rapid freezing has many advantages, and fixation at temperatures below −100° C. produces fewer ice-crystal artefacts in sections. A new method is described in this book for freeze-drying preparations for the electron microscope; in some cases the morphology of the freeze-dried and air-dried material differs, but in others, such as tobacco mosaic virus, the appearances are similar.

Dehydration after freezing is compatible with survival only for small organisms such as bacteria and yeasts, and there is no evidence of survival of mammalian cells with a water-content reduced to 10 per cent. Conflicting results have followed the experimental use of freeze-dried cornea; success has only been achieved in the rat, where the small size of the cornea may enable a non-viable graft to act as a skeleton for the ingrowth of host cells from the periphery. In rabbits such ingrowths would take longer, and may be too late to overcome the opacity developed in the centre of the graft. Freeze-dried blood vessels have been successfully grafted in dogs; but these, like grafts of freeze-dried nerve which do not elicit the homograft reaction, may be successful merely because they provide a scaffold for cells from the living tissue.

Plasma has been successfully freeze-dried for so long that the use of the dried product is accepted not only as equivalent but even as superior to stored liquid plasma. Repeated freezing and thawing of plasma results in instability of plasma proteins, but a single thawing may occur without loss of essential properties before freeze-drying. The useful life of dried plasma varies with the degree of secondary drying, that is, with the residual moisture content and with the type of packing. The British transfusion bottle has an aluminium cap and a rubber washer; since rubber is permeable to water vapour the vacuum is best replaced by a dry inert gas. In the United States the evacuated container is placed in a tin which is also evacuated.

The volume under notice contains articles by fifteen authors, and deals with theoretical and practical aspects of freezing and freeze-drying of antibiotics, bacteria, viruses, blood products, milk and foodstuffs, and the preservation of living tissues. It also deals with the simple apparatus needed to apply freeze-drying techniques to dead tissue for histological work. There are inevitable inequalities in the different articles, but the book should be read by all who use freezing or freeze-drying. Apart from the line-drawings and micrographs, the illustrations are of extremely poor quality. S. T. COWAN

BEGINNINGS OF A WELFARE STATE

Studies in the Social Services

By Sheila Ferguson and Hilde Fitzgerald. (History of the Second World War: United Kingdom Series.) Pp. ix+367. (London: H.M. Stationery Office, and Longmans, Green and Co., Ltd., 1954.) 22*s.* 6*d.* net.

PROF. R. M. TITMUSS ends his penetrating social history of the Second World War, "Problems of Social Policy", by saying, "The disturbances to family life, the separation of mothers and fathers from their children, of husbands from their wives, of pupils from their schools, of people from their recreation, of society from the paths of peace . . . have left wounds which will take time to heal and infinite patience to understand". This present book, which although not written by Prof. Titmuss conforms closely to plans made by him, is, like its predecessor, a valuable contribution to our knowledge of family strengths and weaknesses, as revealed in a period of serious and prolonged strain; knowledge which is vital to the wise ordering of social policy. Except for the study of the nursing service, which, interesting as it is, does not really fit into the pattern of the book as a whole, the book is centred on the family. It starts with the family as it was in 1939, already reduced in size by the decline in the birth-rate during the previous half-century, and therefore with fewer members to call on for support and help in times of crisis, and discusses the strains to which it was subject—strains such as the dispersal of individuals, and, in bombed cities, whole neighbourhoods, the mobilization of husbands and fathers, the "unparalleled mobilization of women, and in particular, married women"—and how they were met.

Dislocation of family and neighbourhood life meant that there were many things which the family could no longer do for itself, and what the family and neighbourhood could no longer do for themselves the State must help them to do. The growing recognition by the Government and its various departments that it must help the family bear its responsibilities if women's efforts to "keep their homes together in the face of every adversity" were to be successful comes out in all the studies of which the book is made up. It is shown, for example, in the development of the emergency maternity service from a safety to a welfare measure, and in the new and extended functions which the Government assumed in connexion with the welfare of young children, both of which developments are here discussed at some length. Moreover, this participation by the State in family responsibility was, with some hesitation and certain exceptions, offered to all families who cared to take advantage of it; and these studies confirm the view expressed in "Problems of Social Policy", that one of the most far-reaching changes in social policy and administration which took place during the war years was the increasing readiness of the State to assume responsibility for warding off distress not only from the poor but also from all classes of society. Hence social service benefits came to be regarded by all concerned as among the rights of citizenship, a conception which is fundamental to the Welfare State as we know it to-day.

In general, one gains the impression from these studies that "the social stability of families as a whole, and of the nation as a whole was, under the circumstances, remarkable". Breakdowns inevitably occurred, however, and, as originally planned, this book would have contained studies of at least three symptoms of family breakdown—the war-time increases in juvenile delinquency, divorce and illegitimacy. Unfortunately, limitations imposed by the publication time-table only permitted the inclusion of one study, that of illegitimacy. This provides the material for two of the most interesting chapters of the book, chapters which demonstrate that the more careful examination of relevant statistics may lead to conclusions about the nature and extent of a social problem very different from those generally accepted. Thus, while the remarkably rapid rise in the number of illegitimate maternities from 26,569 in 1939 to 64,743 in 1945 has led to generalizations about the lowering of moral standards, especially among young people, the authors show that this contention cannot be supported if we relate these statistics to those relating to pre-marital conceptions. The war-time rise in illegitimate maternities was accompanied by an almost equally dramatic fall in the percentage of irregularly conceived maternities afterwards regularized by marriage; and, in fact, it was not until 1945 that the percentage of maternities conceived out of wedlock to all maternities rose above the pre-war figure. Moreover, when analysed according to the age of the mother, it was found that it was among the women over twenty-five rather than among their younger sisters that the rise had taken place. No attempt is made by the authors to arrive at a confident explanation of the situation thus revealed; this, they state, must await "a much more searching analysis of all the social, economic and psychological factors concerned in contemporary attitudes to sex relationship and marriage".

Despite its inconclusiveness, this sentence exemplifies a breadth of outlook which is characteristic of the book as a whole. Nowhere are war-time problems and policies studied in isolation; instead, we are continually brought back to the consideration of fundamentals of social need and national policy. Hence, although the studies contained in the book are specific and limited, they are likely to be of long-term value to both student and administrator.

M. P. HALL

YEAST TECHNOLOGY

Yeast Technology
By John White. Pp. xvi+432+17 plates. (London: Chapman and Hall, Ltd., 1954.) 55s. net.

THIS volume makes a welcome addition to the already large literature of commercial yeast technology. The author states in his preface that it is largely the outcome of a series of papers communicated by him to various journals, and in its general make-up it certainly bears unmistakable traces of its origin. There is a good deal of needless repetition which could have been obviated by more careful editing.

The greater part of this book is concerned with the manufacture of bakers' yeast on a commercial scale, as well as the important questions of quality of the product and biological control. From a reading of these chapters it is obvious that the author is a master of his subject. They could not well be bettered, and should be studied by every beginner entering the field of commercial yeast production. Unfortunately, when the author strays from his chosen field his touch is by no means so sure. The chapters on yeast genetics and food and fodder yeasts, for example, should either be entirely omitted or very greatly expanded. The chapter on yeast genetics as it stands at present is too scrappy and inadequate to be of any real service to a beginner. The treatment of brewers' yeast is also not very adequate. The chapter on this subject has been contributed by Dr. C. Rainbow, and it is clear that he has been hampered by lack of space; but he has certainly used the space he has been allowed to good purpose. In another edition this chapter should also be very greatly expanded. It would, for example, have been of great help to the practical brewer to be given more details of how to select his pitching yeasts and how to maintain his stock cultures in an active state.

The main purpose of this volume is to describe the commercial manufacture of bakers' yeast; and this is done with a wealth of detail in the early chapters and should be of the greatest value to beginner and experienced worker. The remaining chapters, apart from those on yeast genetics, food and fodder yeasts and brewers' yeasts, are concerned with such important subjects as yeast nutrients, structure and consistency of yeasts, aspects of yeast physiology and disposal of effluents from yeast factories. There are also chapters on the effect of aeration and temperature on yeast growth, and these will repay careful study.

The chapter on the microbiological control of yeast growth processes is particularly well done; but in another edition the author should give full details of how stock cultures of bakers' yeast are maintained and how fresh cultures are selected.

The information on the behaviour of bakers' yeast during panary fermentation is up to date and should be studied by every baker, even if he has only a rudimentary knowledge of chemistry. It may prevent him from laying the blame at the yeast manufacturer's door for his own mistakes.

The publishers are to be congratulated on the general make-up of this book; the quality and clearness of the various illustrations and diagrams are excellent and leave nothing to be desired. Apart from the criticisms which have been made—and they are all of a minor character—this book can be strongly recommended and should be acquired by everyone interested in this subject.

E. BARTON-WRIGHT

COSMIC EVOLUTION

Stars in the Making
By Cecilia Payne-Gaposchkin. Pp. xii+160+67 plates. (London: Eyre and Spottiswoode (Publishers), Ltd., 1953.) 25s. net.

THE early writings of Dr. Payne-Gaposchkin (then Miss Cecilia Payne) provided much of the empirical knowledge that was used to test the theoretical predictions made by the late E. A. Milne and his contemporaries in their classical researches on stellar atmospheres. She has since become a leading worker on variable stars. In the present book she ranges over a wider field and addresses herself to a wider class of readers than in her previous writings. In doing so she reveals a talent for brilliant and stimulating exposition.

Dr. Payne-Gaposchkin calls her theme the drama of cosmic evolution. In her first two chapters on "The Actors" she gives a vivid description of the physical variety of the stars and of the physical conditions of interstellar material. The next three chapters describe "The Scene" that is witnessed by astronomical observation. In the reviewer's opinion, this is the best part of the book and includes much information that has not before been presented in a popular account. It deals with the physical characteristics of double stars, clusters of stars and the strikingly different stellar sequences found in galactic and in globular clusters, with galaxies and, particularly informatively, with the comparative study of the Milky Way galaxy and the Andromeda nebula, and with Baade's two stellar populations and the varying manner of their occurrence in different galaxies. Most of the collection of sixty-odd splendid plates at the end of the book illustrate this section. Several important observational advances in the past two years would have permitted some statements to have been made in a more categorical form had they been available when the book was being written.

The "Drama" itself has to be inferred from the analysis of this scene. Dr. Payne-Gaposchkin marshals the inferences that can be made about the ages of various astronomical systems and then seeks to show that other general indications are compatible with these in suggesting a certain evolutionary sequence. Many of her ideas are in keeping with some current trends in astronomical thought (though she does retain the now generally rejected fission theory of the origin of double stars). However, one would wish to see the ideas brought into closer relationship with theories of stellar structure at one extreme, and with some theory of the formation of galaxies at the other, before venturing an opinion upon them.

Dr. Payne-Gaposchkin likens her undertaking to trying to reconstruct the story of a film from the array of still pictures displayed outside a cinema. Her own reconstruction will provoke lively curiosity—even if the display does not yet carry the announcement, "coming shortly".

W. H. McCREA

OBSERVATIONS ON THE COLLAGEN SYSTEM*

By Prof. J. T. RANDALL, F.R.S.

Wheatstone Physics Laboratory and Medical Research Council Biophysics Research Unit,
King's College, London

ALTHOUGH it is impossible for one group of workers to examine more than a few fundamental features of so complex a biological system, I wish to emphasize the need for an integrated outlook if we are to reach a proper understanding of the nature, structure and function of connective tissues. The physicist, in thinking of connective tissues, almost automatically concentrates his attention on the structural properties of the fibrous collagen; the biochemist likewise tries to characterize the protein by a precise analysis or to determine, perhaps, what sugars are present in the ground substance. The histologists and pathologists are aware more than any of us that these are but facets of the whole problem. Collagen fibres are a characteristic feature of all connective tissues and their derivatives, cartilage, bone, and lymph nodes. But all connective tissues are composed of four main constituents: cells, fibres, matrix or ground substance, and intercellular fluid. It is too often forgotten that the cell is the focus and origin of all tissues. If we are to reach a better understanding of the collagen system, more attention must be paid to the fibrogenic cells, to which the fibres and ground substance in all probability owe their origin. Here I shall consider three main types of problem: first, some biological and biochemical studies of fibrogenesis; secondly, physical investigations of collagen structure by means of X-ray diffraction and the electron microscope; and thirdly, the mechanism of precipitation of fibrous collagen from *in vitro* solutions.

Fibrogenesis

While it is recognized that development of fibrous material occurs outside the cell, the origins and early fibrogenesis of collagen fibrils have remained uncertain since the time of Schwann. Does the fibrous component of the connective tissues originate within the cytoplasm of the fibroblasts, on the cellular surface, or in the regions which lie between the cells? If the fibrils originate in the intercellular medium, it has to be decided whether they are formed or developed with the aid of a specific cellular secretion; such a secretion may itself be precipitated in the form of fibrils, which later develop into much larger entities and bundles. Alternatively, the postulated secretion may interact with the intercellular medium to form a fibrous complex.

By the use of the embryos of the fowl and of the rat, and particularly in tissue culture, the living fibrogenic cells have been examined by phase and ciné-microscopy. Fixed cells have been studied intact and as thin sections in the electron microscope, and cytochemical tests and biochemical assays have been carried out. Two types of structure have been observed: cytoplasmic filaments 100–500 A. in diameter, and cytoplasmic granules 0·5–3 μ in size. It is not known at present whether the filaments have any direct connexion with the cytoplasmic tubules and lamellæ observed by other workers in different types of cell. The filaments have been found in the four main types of cell associated with the rapid formation of collagen: in osteoblasts of the metatarsus periosteum and of membrane and endochondrial bone; in young osteocytes; in fibroblasts of tendon sheaths and the perichondrium; and in chondroblasts of hypertrophic cartilage. In the fibrous sheath of developing bone, the young osteocytes contain these structures, and no clear division can be seen between the cell boundary and the matrix. These observations are suggestive: but it is not yet known whether the filaments are collagenous; they may consist of some core material on which collagen is laid down. Although the filaments are a characteristic feature of the fine-structure of fibrogenic cells, they may not be concerned directly in the production of collagen.

Miss S. Fitton Jackson, who has made the observations I have described, has also directed attention to cytoplasmic granules in these cells. These had been observed previously by Fell and others but largely ignored owing to the ease with which they may be lost in the fixation process. The granules may be seen most readily in the living cell. Detailed studies show that the granules are complex in structure, and staining shows the presence of polysaccharide after removal of lipids and glycogen; the granules also stain characteristically for protein but do not respond to the Janus green stain for mitochondria.

From these and other observations it is reasonable to conclude that the granules are largely composed of an acidic polysaccharide–protein complex and show indications of phosphatase activity; possibilities of the presence of other components and enzymic activities cannot at this stage be excluded. Bottle cultures of almost pure strains of osteoblasts are providing material for detailed biochemical investigation by R. H. Smith. The granules may have a secretory function and be concerned either in the elaboration of the ground substance or of simpler molecular systems. There is at present no connexion between the cytoplasmic granules and filaments, but this possibility cannot be ignored.

Structure of Collagen

It is well known that collagen fibres possess a degree of structural organization found in few, if any, other proteins. About twelve years ago, electron microscope studies revealed an axial macroperiod of $\sim$ 640 A., which has since been confirmed in collagens of widely different biological origin. This macroperiod has been found to be subdivided into a number of striations generally alternating in density. The macroperiod has been confirmed by low-angle X-ray diffraction, an aspect studied in great detail by Bear. High-angle X-ray studies reveal an imperfect fibre diagram which has been known for about thirty years. This diagram relates to the configuration and structure of the individual polypeptide chains or protofibrils, and differs in important ways from the characteristic diagram of the keratin–myosin–epidermin–fibrinogen group. Many models for the protofibril structure have been proposed, especially in recent years, but no satisfactory solution has yet been reached. As I shall show, new data are being obtained almost continually, suggesting new lines along which the investigations may proceed towards the complete derivation of the structure.

---

* Substance of the 6th Procter Memorial Lecture delivered in the University of Leeds at the Annual Meeting of the Leather Trades' Chemists Association, September 24.

Although little is known about the structural arrangement within the 640 A. period, sub-bands of smaller size are frequently observed in electron micrographs. P. M. Cowan, A. C. T. North and I have recently obtained some evidence from coherent and diffuse X-ray scattering at small angles for the existence of a sub-unit of dimensions 220 A. along the fibre axis and 40–90 A. at right-angles. Attempts are also being made by R. E. Burge to relate the electron microscope results to the X-ray results by a determination of the density function for unstained and unshadowed pictures. In undried native fibres the unit also appears to be greater than that of the individual protofibril, as shown by the equatorial reflexions of quite large spacing obtained recently by North. These reflexions are not observed if the fibre is dried thoroughly and then re-wetted.

North has also obtained much improved high-angle diagrams by the technique of stretching; these results cannot be discussed in detail here. They are, however, remarkable for two things. First, the improved diagrams point much more strongly than any previously obtained to a helical configuration of the protofibrillar unit; it is the details of the helical configuration which are still baffling. Secondly, a comparison of the fibre extensibility with that derived from the low- and high-angle diagrams supports the suggestion of Bear that two types of region exist in the fibre and that these regions differ in their degree of order.

The absence of meridional reflexions between the equator and the 2·95 A. arc on the X-ray diagrams of stretched specimens, and the relationship 1/2·95 − 1/4·27 = 1/10·14 between the spacings of the strong layer lines, would be expected from a helical configuration with a unit repeating at heights of 2·95 A. and a pitch of either 10·14 A. or 4·27 A. The repeating unit may consist of one or more residues. The 10 A. pitch could be produced by (i) a single chain having a lead of 10 A. and about 3⅓ units per turn; (ii) two intertwined helices each having a lead of 20 A. and about 6⅔ units per turn; (iii) three intertwined chains each with a lead of 30 A. and 10 units per turn. (i) and (iii) each has an approximate pseudo-period of 30 A. and (ii) one of 60 A. A 4 A. pitch might similarly be produced by one, two or three interwoven helices with leads of 4 A., 8 A. and 12 A., respectively. The observed spacings have been indexed according to layer lines of a 30 A. period, but the fit is not exact. In practice, a helical structure may have a very long pseudo-period to which these systems of small layer-line indices would be approximations.

Mechanism of Collagen Precipitation

The precipitation of collagen from acid solution has been known for many years, and recent interest in the subject arises from the discovery that such precipitates may contain fibrils with substantially the same structure as the native material. The study of the conditions under which such fibrils are formed *in vitro* is likely to be of importance in the general study of fibrogenesis, on which we are engaged, and of long-chain polyelectrolytes. Broadly speaking, four types of precipitate have been found: (i) gels which contain no fibrils; (ii) fibrous precipitates of collagen induced by the addition of simple salts or *p*H changes; the detailed structure of these fibrils is very similar to that of native collagen; (iii) fibrous precipitates induced by the use of complex molecules (anions), such as acid glycoprotein, chondroitin sulphate, etc.; the periodicity of such fibrils is not characteristic of native collagen and ranges from 2000 to 3000 A.; (iv) if small amounts of adenosine triphosphate are added to collagen solutions, not fibrils but segments are produced of similar periodicity to the fibrils of (iii).

F. O. Schmitt's laboratory has been largely concerned in the study of types (iii) and (iv), and F. C. Kelly has recently carried out interesting experiments on the interrelationships of various precipitates. Collagen molecules in acid solution at a *p*H of ~ 3 are probably random coils with a net positive charge arising from the excess of charged arginine, histidine and lysine groups over the negative carboxyl groups of glutamic and aspartic acids. As the *p*H rises to that at which precipitation may occur, it is likely that the molecules become helically coiled, under which condition roughly one charge of each sign exists per turn of each chain of the helix.

Mr. F. Booth and I have been investigating theoretically the conditions for the precipitation of long, thin, charged molecules, and it turns out that collision dynamics may be ignored and the problem investigated by a study of van der Waals and electrostatic interactions. At the present time, the helical model referred to above in which positive and negative charges alternate along the length of the helix has not been completely worked out, but it is clear that the step-wise distribution of charge may be important. More detailed work has been done on the interaction of long thin molecules with a smooth charge distribution. If molecules attract each other in all relative positions, the resulting precipitate would have no ordered structure. On the other hand, if attractive forces exist only when the molecules are parallel to each other, the precipitate would be fibrous. Van der Waals forces will always tend to orientate neighbouring molecules so as to bring them parallel.

An interesting feature of the models already studied is that, when the net force is attractive, there will be a turning moment tending to align the molecules, and this moment increases rapidly as the angle between the molecules decreases. I have recently shown experimentally that collagen fibrils of normal characteristics may be produced by nothing more complicated than a change of *p*H. This adds weight to the argument that collagen precipitates appear to be controlled by the van der Waals and electrostatic interactions of neighbouring molecules. Thus a rise of *p*H reduces the net positive charge to the point where overall attraction and precipitation result. Precipitation by salt arises from drastically reduced Coulomb interaction, due to increased screening by the ionic double layer.

In the more complex instances of fibrous-long-spacing and segment-long-spacing precipitates, we must be careful not to assert that the interaction results in a purely collagenous precipitate. This seems highly unlikely, and the evidence at present suggests that these systems are complexes of collagen with an interacting anion.

It seems significant that structure in great variety exists in all these precipitates, and it is not unlikely that the phenomenon of structure arises from some as yet unknown peculiarity of collagen. The details of structure depend more on the nature and stereochemistry of the interacting molecules.

In concluding this account it is a pleasure to pay tribute to the enthusiastic efforts of the colleagues whose work I have largely described, and the invaluable support of the technical staff of the laboratory.

TREE GROWTH ON ACID SOIL

A JOINT session of Sections K (Botany) and K* (Forestry) of the British Association devoted the whole day at Oxford on September 7 to a symposium on "The Interactions between Acid Soils and Forest Trees". Biologists whose joint research interests covered a wide variety of subjects combined with practical foresters in an attempt to solve, or at least to re-state in simpler terms, the problems of establishment and maintenance of forests on heathy and peaty soils.

Mr. M. V. Laurie, chief research officer of the Forestry Commission, opened the discussion by presenting the forester's point of view, based upon the thirty-five years experience of the Commission. He pointed out that much of the land at present available for reafforestation in Britain is acid and that two classes of problems therefore exist. First, the problems concerned with the effects of acid soil on the establishment and growth of trees; and secondly, those concerned with the effects of the trees themselves upon soil fertility. Soil is the working capital of the forester and he has therefore a duty of maintaining it, undiminished in productivity, in perpetuity while producing the right crop of the highest quality.

On the land available, the solution of the problems of tree establishment consumed much of the early effort of the Commission. Preliminary treatments such as ploughing, draining and the application of fertilizers are effective on many sites; but the degree to which they are valuable and the magnitude of the improvement in tree establishment that they produce are not easily predictable. The full interpretation of the results of early successes and failures demands not only long-term experiments on a large scale but also the co-operation of experts. The effectiveness of mixtures of Sitka spruce and Japanese larch or pine, the beneficial effects of broom on spruce growth and the universally adverse effect of heather on all tree species must be interpreted by ecological experimentation. The stimulation of many species by phosphate on sites where lime and nitrogenous fertilizers are ineffective requires the co-operation of physiologists and microbiologists for explanation. Microbiologists, too, must assist in helping to determine the rival claims of organic manures and composts as against balanced applications of artificials. All these problems concerned with forest establishment are in the process of being solved with the help of specialists, but the long-term question of fundamental importance—the effect of trees on the soil—remains.

The vigorous forests of young conifers which have been established are undoubtedly changing the soil. In the place of the much modified heath soils, acid woodland mor with a deep layer of needles is being produced. It is held by many ecologists that mor conditions lead to serious soil degeneration. Two points must be considered in this regard. First and foremost, the demand for timber is mainly a demand for pine and spruce. A supply of poor-quality hardwood, even if such a crop prevented mor formation, would not be economic. Secondly, it would seem that what we believe to be natural northern coniferous forest exists almost exclusively on mor or podsolized soils as a self-regenerating natural forest.

Dr. G. W. Dimbleby, of the Department of Forestry, Oxford, was opposed to the view that mor conditions should be allowed to develop in newly established forests. He stated that podsol and its attendant raw humus layer form an undesirable medium for the growth of forest in Britain and it is, moreover, avoidable. Dr. Dimbleby described the work of a research team in Oxford which had undertaken fundamental research on many aspects of tree nutrition. The team concentrated its attention on areas in Yorkshire, where tree establishment on high-level heather moors is beset with great difficulty. It has often been stated that these moors are a natural ecological climax. This view has been shown to be erroneous by the study of the soil surfaces and profiles beneath bronze-age earthworks. On the surface below these artificial mounds, charcoal of birch and oak is found on the sites of hearths. The soil surface is rich in the pollen of hazel, oak, lime and alder and lacking in heather pollen. The soil profile below is typical of a brown forest mull. Indeed, the podsol profile of the heath goes over the top of the earthworks and is undoubtedly of more recent development. The vegetation and the soil have undergone a change from mixed deciduous forest on brown earth to heath on podsol since bronze-age times, and evidence suggests that man's activity in cutting, burning and grazing is the cause. Nowadays, when burning and grazing are prevented, birch and pine may seed themselves into the heaths. Of these, birch becomes established, its roots break through the iron-pan of the podsol and its leaf litter and the detritus from associated plants convert heather mor to mild humus so that a forest soil with a vigorous fauna becomes established. Pine, on the other hand, fails to break the pan, and the mor conditions and bad drainage are exaggerated, and acidity and poor nutrient status are maintained.

The effects of birch in this sequence are essentially similar to the effects of soil treatment. Ploughing causes breakage of the pan and improves drainage and aeration. Mulching and manuring temporarily simulate the beneficial nutritional status of mull. If pine is planted this improvement is reversed; and leaching and podsolization develop with the accumulation of deep needle litter in which vast stores of minerals, which would otherwise be available, are locked.

The beneficial effects of birch and other species under which brown earth develops can probably be partly interpreted in terms of the behaviour of their litter during breakdown. The cellulose in the walls of the mesophyll of heather and mor-producing species is protected from breakdown by a resistant layer of a tannin–protein complex which is laid down upon them as they die. This is usually lacking in species not producing mor and, indeed, admixtures of birch litter or extracts of it can be used to stimulate breakdown of mor.

Prof. L. G. Romell, of Sweden, who was guest speaker, discussed the formation of mor. He pointed out that the humus turnover in mull soils is not faster than that in mor, and indeed the amount of organic matter is often higher in them. Moreover, when mor is isolated and stored, loss of organic matter and release of available nitrogen occur. The form of the curves relating these changes with time of storage is such as would be expected when a material high in nitrogen content is available for decomposition. The application of lime to decomposing mor in storage increases the rate of loss of organic matter but decreases the rate of release of available nitrogen. The immobilization of nitrogen in the presence of lime is due in part to reaction of ammonia with quinoid complexes in the humic matter.

The examination of a mor profile shows it to be characterized by a great concentration of roots, mycorrhizas and mycelia. Acidity is not, however, a diagnostic character of mor because mull may have a similar pH range. In beech soils, mor develops inevitably as the forest ages, so that liming and forest treatment cannot arrest the change from mull to mor. In the time of P. E. Muller (who first used the terms 'mor' and 'mull' in their present sense) mor was widespread in Denmark; now it is rare. The old beech stands are gone, and in the young forests mull exists in its stead. Similar parallelisms between mor development and the age of stands are found throughout the spruce forests of Sweden.

The factors affecting the development of mor have been analysed by ecological experiment. Addition of nitrogenous manures causes stimulation of ground flora and tree growth on mor soil. Other fertilizers have little effect. The death of trees from natural causes or felling is followed by a quick response, and dense ground flora develops. Trenching experiments where roots are cut have similar effects, producing dense ground flora, high nitrogen and phosphorus content of vegetation and the disappearance of the mor profile. All these experiments, taken in conjunction with estimates of the release of available nitrogen during storage, indicate that the prime factor in mor formation is nitrogen starvation. The intensification of competition for nitrogen by roots and mycelia as a stand ages leads to formation of mor, decrease of ground vegetation and slow growth of trees. Such a view of the mechanism of formation of mor, although it runs counter to many accepted teachings, explains more closely the ecological and experimental data.

The wide experience of Prof. Romell and the intensive researches of the soil nutritional team described by Dr. Dimbleby seemed, therefore, in full agreement concerning the relative productivity of mor and mull and the need to prevent development of mor. Suitable sylvicultural measures could prevent its development, and these were dealt with in subsequent discussion.

Dr. S. D. Garrett described work done at the Botany School, Cambridge, on the microbiology of acid soils with respect to soil-borne disease. He took two examples where there is an apparent correlation between pH and intensity of disease. Both in the case of *Fomes annosus* butt-rot of pines and spruces and in *Pythium* disease of seedling roots, disease is less intense in acid than in alkaline soils. The diminution of the damage caused by *Fomes* on acid soils can be ascribed to an effect of pH upon the soil micro-flora rather than upon the pathogen or host. *Fomes* spreads inside and along the surfaces of living roots and passes from host to host by root contact. Rapid advance along the root-surface, leading to widespread disease, is possible on alkaline soils, because *Trichoderma viride*, a virulent antagonist of *Fomes*, is absent. On acid soil only an internal spread of *Fomes* is possible, and the disease is of less importance. *Pythium* diseases of seedling conifers are also less intense on acid soils and in this respect they contrast with similar diseases of crucifers. The effect of pH may here be ascribed to a direct effect on the host and not upon the pathogen. The ecological optimum of conifers lies on the acid side of neutrality, so that they resist the disease on acid soils.

Although these examples illustrating the causes of increase or decrease of virulence with soil conditions appear simple when the final conclusions are reached, they are based upon wide ecological surveys in which apparent correlations, many of them spuriously giving the impression of causation, are observed. Such observations must be followed by detailed controlled plot and laboratory experiments.

Dr. J. L. Harley, of the Department of Botany, Oxford, also discussed soil microbiology in an attempt to fit work on the physiology of mycorrhiza done in Oxford into its ecological perspective. The concentration of roots and mycelia in the mor profile described by Prof. Romell is easily observable in beechwoods in Britain. Estimates of weights of absorbing roots in various horizons of mull and mor confirm the intense colonization of the *F* and *H* layers of the latter. These roots are mainly mycorrhizas and are completely clothed in a tissue of fungus through which all nutrients entering the tree must pass. Observations on spruces by Wilde in America and on beech in Oxford show that similar subsurface aggregation of roots can be induced by treating even highly nutritive soils with excessive surface layers of organic material. Following the aggregation of roots, starvation symptoms can develop. The conditions in which mycorrhizal roots show their greatest development are these conditions of intense competition for nutrients. It is possible with beech, as has been shown in Sweden and America for pine and spruce, to vary the intensity of mycorrhizal infection by arranging a deficient supply of nutrients in the soil while ensuring rapid photosynthesis and carbohydrate production. The ecological conditions of intense mycorrhizal formation are those in which growth-rate may be small. Indeed, an inverse correlation of growth and mycorrhizal infection is often observed in natural conditions. Such correlations provide no evidence concerning the functioning of mycorrhizal organs, which must be sought in laboratory experiments.

If conventional physiological methods of studying nutrient absorption by roots are applied to mycorrhizal roots, it is readily shown that they accumulate salts in their tissues. The rates of accumulation of phosphate, ammonia and the alkali metals are rapid, and the mechanism of absorption is linked with metabolic activity. The rate is very sensitive to temperature, oxygen supply and the presence of metabolic poisons. It is very rapid in oxygen concentrations approximating to that in air and, in some conditions, is closely correlated with oxygen consumption in respiration. Comparisons of the rate of absorption of minerals by mycorrhizal and non-mycorrhizal roots of beech and pine show greater rates of accumulation into mycorrhizas of all salts tested. The mycorrhizas may therefore compete on more level terms than uninfected roots with the mycelia and other roots in the soil. The primary destination of the salts absorbed is into the fungus, and phosphate in particular accumulates in the fungal layer at first, so that during absorption the supply of phosphate to the host tissue is no greater in mycorrhizal than non-mycorrhizal roots.

Two mechanisms have been studied by which the ions trapped by the mycorrhizal sheath of fungus can be made available to the host. First, it has been shown by direct observation and photographic record that beech mycorrhizas have a life-period of about eight months only. Hence there is a periodic release of mineral-rich organic matter into the actual rooting region of the host. Secondly, there is in the tissues a metabolic turnover of phosphate, sensitive to oxygen and temperature, the net result of which is the movement of phosphate from fungus to host during periods when the rate of uptake is low. Hence, during periods of rapid release of minerals from newly fallen litter, nutrients may be trapped and accumulated in the fungal layer of mycorrhizal roots and, in the subsequent periods of slower mineral release, phosphate and perhaps other minerals are passed to the host. Laboratory physiological experiments, therefore, are providing a credible picture of the functioning of mycorrhizas in ecological conditions.

Dr. L. Leyton, of the Oxford Forestry Department, described detailed work on mineral nutrition of conifers which has been carried out in the same areas as that described by Dr. Dimbleby. His description of the soil profiles of sitka spruce forest in Yorkshire was exactly comparable with that of previous speakers, and his analysis of mor and mull again emphasized the deficiencies of available soil nutrients, especially of nitrogen. Significant increases of growth were obtained by the application of nitrogenous manures, and little increase was obtained with phosphate. Dr. Leyton described the technique of analysis of foliage to determine the nutrient status and mineral deficiencies of the site. On untreated soils, needle weight and nitrogen content are positively correlated, and the effects of the use of nitrogen fertilizers, removal of heather and mulching owe their efficacy in promotion of growth to increase of available nitrogen. Application of phosphate only affords a secondary stimulation.

The humus layer contains as much as 2 per cent of dry weight as nitrogen, so reasons were sought as to why this is not made available. Calcium deficiency is very marked, and it is possible that microbiological activity is limited by this factor. On the other hand, the soils in question are often water-logged in winter and dried out in summer. This adverse water régime may be counteracted by mulching, which results in a rapid increase of microbiological activity in the rooting layer.

The method of needle analysis has proved very valuable in this study, for it can be used to predict as well as to follow the effects of soil treatments on trees of any size. In all cases where treatments improve growth, an immediate response in needle colour and weight precedes increased growth. The needles of the following year's crop are laid down in the buds of the current year, so that although immediate growth response to treatment is not observable, the constitution of the needles provides a satisfactory basis of prediction of growth in the future.

With these set papers as a background, the whole subject was discussed. Prof. Romell pointed out that the effects of liming are complicated because of the stimulation of white rot fungi above pH 4·5, and the lack of effect of lime treatments mentioned by Mr. Laurie and others might be explained by the trapping of nutrients by them. He asked about the stimulation of turnover in mor by hardwood litter, and Dr. Dimbleby and Mr. Murphy stated that it can occur and is associated with increase of faunal activity. Dr. Dimbleby spoke strongly in favour of developing stands of mixed tree species, but Mr. Hiley emphasized that adequate thinning of conifers would encourage ground flora, the detritus of which would have the required effect of reversing the tendency to formation of mor. He also described how mor develops under old oak stands and how felling of such stands and replanting with conifers may give rise to mull with an *Oxalis* and *Rubus* ground-flora. Dr. Harley pointed out that such a change might be the result of felling and planting rather than an effect of the conifers themselves. Mr. Laurie showed that there are still untouched problems concerning the factors leading to the aggregation of roots so characteristic of mor. He asked if some of the known effects of mycorrhizal and other fungi on the growth and branching of roots could be a factor in the process. Dr. Harley and Dr. Leyton suggested that a study of oxygen supply and water supply in the surface soil layers would perhaps be a better first approach to these problems, as both these factors greatly affect root-growth and activity. Prof. W. H. Pearsall, who was in the chair, commented that although there was clearly evidence that many of those present disagreed on various grounds with the planting of conifers on many sites in Great Britain, no battle had developed on this subject. The first problem in reafforestation, he said, is to make difficult sites productive and then to ensure that their soil tends to change towards mull rather than away from it. Britain is a region of brown forest soils, and present policy should be to re-establish them. No doubt it was felt that such a discussion would lead the meeting away from biology into economics, for in spite of this challenge no battle developed.

The meeting was a highly successful discussion of a most important subject, and indeed was a hard but valuable day's work for those who took part.

ANIMAL BEHAVIOUR

AT the recent meeting of the British Association in Oxford, Sections D (Zoology) and J (Psychology) held a joint discussion on "Animal Behaviour", which was attended by some four hundred members. The discussion dealt with the study of animal behaviour as it is practised by Konrad Lorenz and other zoologists who follow his lead. These investigators usually refer to themselves as ethologists, and the first two papers presented some of the features of their method, some of their findings, and some of their theoretical concepts. The third paper was given by a psychologist, who considered some of the relations between ethology and psychology.

Dr. N. Tinbergen (Department of Zoology and Comparative Anatomy, University of Oxford) opened the discussion with a paper on the bearing of the ethological study of animal behaviour on the study of human behaviour. He began by stressing the need for restraint in making comparisons between animals and men, and by saying that, in his view, the importance of Lorenz's work, and of ethology generally, lies not so much in any new theory of behaviour that has been put forward as in its particular type of approach. This approach sets great store on careful observation and description of the behaviour being studied; on qualitative analysis as a prerequisite of quantitative measurement; on study of the whole behaviour in question, not merely of one particular part or phase or aspect; and on the preservation of a proper balance between study of the causation of behaviour and study of its evolution and survival value.

He then discussed certain aspects of the study of inborn behaviour—behaviour "as it appears before conditioning and other learning processes set in". Each animal has a limited repertory of movements, each of which is characterized both by its causes (internal and external) and by its overt motor-pattern. Ethology investigates both characteristics. In connexion with the begging response of the herring gull chick, for example, it has been shown, in relation to the stimuli, that, in eliciting the begging response, the red patch on the parent's beak (or a similar patch on a cardboard dummy) is of great importance, and that here, as elsewhere, "only very few of the receivable outside messages are influential"; and it has also been shown, in relation to the response, that it is an innate motor-pattern, since it is exhibited before the chick can have practised it and is non-modifiable and difficult to condition.

Similar studies of human behaviour are far more difficult, and often inadmissible. Yet there are perhaps indications of inborn mechanisms—specific responses to specific stimuli—in certain anti-predator reactions of human beings, in the infant's reaction to the mother's smile, and in other behaviour patterns.

Dr. Tinbergen also referred to ethological work on motivation. The motivation expressed in a movement can be recognized, he said, by the form of the movement, by the effect of the movement and by the specific factors attending its occurrence. Often there is mixed or ambivalent motivation, as in the alternating movements of attack and escape to be seen in animals and in boxers. There are also 'displacement activities'. These are patterns of behaviour that "do not belong to the motor pattern of the instinct that is activated at the moment of observation"; they are expressions of some other instinctive drive, and they act as outlets for a surplus of motivation, the discharge of which through the normal paths is in some way prevented—as when the aroused but baulked fighting instinct of domestic cocks finds an outlet in food-pecking movements. Although displacement activities are by no means rare in man, and may well have an important bearing on neurotic behaviour, they are not as easily identified in man as in animals, because, whereas a true displacement activity is always an innate pattern, in human behaviour learned patterns, like lighting a cigarette, or handling keys or handkerchief, also often function as outlets for displaced motivation.

In the second paper, Dr. R. A. Hinde (Ornithological Field Station, Department of Zoology, University of Cambridge) sketched five of the ways in which learning modifies inborn behaviour—"behaviour which appears without previous specific practice", as, for example, the 'mobbing' response of chaffinches to owls, which is elicited by a stuffed tawny owl in young chaffinches that have never seen an owl.

First, learning brings about changes in the stimuli that elicit a particular inborn response. Many studies, such as those of Wallace Craig and of W. H. Thorpe and F. G. W. Jones, indicate the importance that early experience may have in the development of behaviour that appears at first sight to be inborn. A particularly dramatic example of the effect of learning on the stimuli eliciting a response is provided by 'imprinting', as when the greylag gosling follows, and behaves towards, the first relatively large moving object that it sees as though it were its parent. In Dr. Hinde's view—and in this he differed from Lorenz—this process is probably not fundamentally different from other forms of learning.

Secondly, learning affects the stimuli which "guide the orientation of behaviour". Here only a few cases have been analysed; but, to take one example, Tinbergen has shown that the digger wasp makes a 'locality study' on leaving its nest, and learns the position of the nest in relation to certain landmarks (a ring of pine cones in one experiment); with the result that, if the landmarks are moved, the wasp repeatedly goes to the new position that they indicate, not to the real nest.

Thirdly, learning sometimes changes the motor-pattern of inborn behaviour. Such modification (except in the intensity of the response) is rare, if not impossible, in the inborn movements used by animals in locomotion, preparing food, nest-building, fighting, courting, and so on; but it occurs extensively in the movements underlying vocal utterances. The bullfinch, for example, can be taught to add whole new tunes to its repertoire.

Fourthly, there is the question of changes, due to learning, in consummatory stimuli—the stimuli to which the animal is particularly responsive while carrying out the instinctive or consummatory act in an inborn pattern of behaviour. Little is yet known about this kind of modification, but it would seem that it must be involved in 'imprinting', and must also be related to 'secondary reinforcement' as understood by Hullian learning-theorists.

Fifthly, Dr. Hinde referred to changes in responsiveness to a constant stimulus, and, particularly, to his work on the waning of the 'mobbing' response in adult chaffinches confronted with a stuffed predator. It has been shown, he said, that underlying this waning of responsiveness there are certainly two processes—one more or less independent of the stimulus and subject to fairly rapid recovery, the other specific to the stimulus and producing a more or less permanent decrement—and probably a third, which is linked to the stimulus and subject to rapid recovery.

In the last part of his paper, Dr. Hinde directed attention to three aspects of behaviour, which, he said, "are brought home rather more forcibly to the field ethologist than they are to the laboratory psychologist". These were: (*a*) that the nature, as well as the complexity, of the things an animal can learn seem often to be determined by its constitution; (*b*) that learning often occurs in animals without any of the conventional rewards, such as food, water or escape from pain, and in circumstances where "the perception of a particular situation seems to act as a reinforcing agent"; and (*c*) that animals are curious, and the analysis of this curiosity is "one of the most urgent problems awaiting both ethologist and psychologist".

To Prof. R. Knight (Department of Psychology, University of Aberdeen) had been assigned the task of discussing aspects of ethology that seemed of special interest to psychologists. He began by referring to matters about which ethologists and psychologists are agreed. Thus they both accept the comparative study of behaviour, including the comparison of animal and human behaviour, as possible and useful. In 1951 Dr. Tinbergen wrote of "the almost universal misconception that the causes of man's behaviour are qualitatively different from the causes of animal behaviour", and no doubt this belief still has its adherents; but psychologists, no less than zoologists, may now be taken to accept the view that the comparative method is as appropriate in the study of behaviour as in anatomy, embryology, physiology or biochemistry. Again, both psychologists and ethologists proceed on the principle that behaviour, in Dr. Hinde's words, "is mediated by the nervous system, and every particular pattern of behaviour is mediated by a particular nervous mechanism or pattern of nervous activity".

The main differences, Prof. Knight suggested, between ethologists and many psychologists, especially American psychologists, relate to theory. Some of the difficulties that psychologists see in Lorenz's theoretical system have been expressed by D. O. Hebb and (though he is not himself a psychologist) by D. S. Lehrman, of the American Museum of Natural History.

Three of these difficulties may be put in the form of questions. First: Is the ethologists' use of the comparative method sufficiently strict? It would appear that Lorenz and Dr. Tinbergen do not always confine their comparisons to what is truly homologous, but are sometimes apt to assume that functionally similar behaviour patterns must be caused by fundamentally similar mechanisms; whereas in fact there is plenty of evidence that, at different evolutionary levels, functionally similar behaviour patterns often depend on mechanisms that are very different in origin and fundamental structure.

Second: Are the ethologists' criteria of innateness satisfactory? They ascribe innateness to all behaviour that appears without previous specific practice, and, in particular, to any behaviour pattern that appears in animals that have been raised in isolation from fellow-members of their species and prevented from performing the particular pattern in question. But, as Lehrman has pointed out, an animal isolated from others and prevented from practising a particular behaviour pattern is "not necessarily isolated from the effects of processes and events which contribute to the development of the particular behaviour pattern"; and cases (for example, the nest-building of pregnant rats) can be given of behaviour which satisfies the ethologists' criteria of innateness but is demonstrably dependent on the animals' previous experience.

Third: Are the ethologists on the wrong tack in looking for unitary, autonomously developing behaviour patterns? For heuristic and other reasons, many psychologists are averse from an approach which regards the development of behaviour as involving the maturation of specific behaviour patterns and of specific mechanisms underlying them. They prefer an approach which, while acknowledging the importance of the physical growth of various structures, regards the development of behaviour as a process in which at each stage new patterns of nervous activity, and consequently new patterns of behaviour, emerge from interaction within the organism and between the organism and its environment.

In the subsequent discussion, Dr. W. H. Thorpe (Department of Zoology, University of Cambridge) said that, in his view, Lorenz's theoretical scheme has greatly stimulated, clarified and simplified the study of behaviour. He referred particularly to its concept of the 'innate releasing mechanism', to its division of behaviour into flexible appetitive behaviour and the relatively rigid consummatory act, and to its distinction between 'directing' and 'releasing' stimuli. He also said that, although Lorenz's theory does take considerable account of innate or inborn behaviour, it is not anti-learning; indeed, it not only accepts the usual kinds of learning but also adds another—'imprinting'. Prof. C. W. Valentine (formerly of the Department of Education, University of Birmingham) said he wished to make it clear that not all psychologists, particularly in Great Britain, are unsympathetic to the idea of instinctive drives and inborn patterns of behaviour. Although the word 'instinct' has for many years been under a ban in American psychology, it is now beginning to reappear, and innate impulses and actions, as well as other constitutional factors, are receiving increasing attention in recent American work in educational and developmental psychology. Prof. T. H. Pear (formerly of the Department of Psychology, University of Manchester) welcomed ethology and its experimental field-studies of birds and a variety of other animals as helping to "break the domination of psychology by American laboratory studies of the rat"; but, while psychologists are right, he said, to be interested in animal behaviour, they must not let this interest so obsess them that they neglect the study of "civilized and sophisticated men and women".

REX KNIGHT

PAUL SABATIER, 1854–1941

By PROF J. R. PARTINGTON, M.B.E.

PAUL SABATIER, the centenary of whose birth fell on November 5, was born of a modest family in Carcassone in 1854. In 1874 he passed high on the lists in the entrance examinations for the École Polytechnique and the École Normale Supérieure. His place (fourth) on the list of the Normale was higher and he chose to go there. In 1877 he was top of the list of graduates in his class. After a year as professor at the Lycée at Nimes, he had the good fortune to become assistant to Berthelot at the Collège de France, where he took his doctorate in 1880 with a thesis on the metallic sulphides. After a year at Bordeaux, he became assistant professor of physics, and in 1883 of chemistry, at Toulouse, becoming professor of chemistry there in 1884 at the early age of thirty. In Toulouse, in spite of an offer to succeed Moissan at the Sorbonne in 1908, Sabatier stayed for the rest of his life, and died there on August 14, 1941, aged eighty-seven*. He became dean of the faculty of science in 1905. He was an excellent and very popular teacher, and long after his retirement, in fact nearly to the end of his life, he continued to lecture. He became *correspondant* of the Academy of Sciences in 1901 and the first non-resident member in 1913. He was Nobel laureate in chemistry in 1912, Davy medallist of the Royal Society in 1912 and foreign member of the Society in 1918, doctor *honoris causa* of the University of

---

* *C.R. Acad. Sci., Paris*, 213, 281 (1941); *Obituary Notices of Fellows of the Royal Society*, 4, 63 (1942–44); *J. Amer. Chem. Soc.*, 66, 1615 (1944).

Pennsylvania in 1926, and Franklin medallist in 1933.

Sabatier's early work was in physical and inorganic chemistry, some of it in collaboration with his pupil, Jean Baptist Senderens. He first obtained pure hydrogen disulphide by vacuum distillation in 1886, discovered new metallic nitrides, and studied nitrosodisulphonic acid. He also made thermochemical measurements. His most famous work, begun in 1897 and occupying him for thirty years, was a study of the applications of heterogeneous catalysis in organic chemistry, of which he published a summary in his book, "La Catalyse en Chimie Organique", 1912. Although platinum had long been used as a contact mass, and the associated Dutch chemists in 1796 had found that alcohol vapour when passed over heated alumina is decomposed into ethylene and steam, little or no application of catalysis in organic reactions had been made. Sabatier became interested in this field by Mond's work on nickel carbonyl, and he used nickel, as well as other finely divided metals such as copper, as catalysts.

At that time there were two theories of heterogeneous catalysis. Faraday in 1833 had suggested a physical theory that one or more of the reacting gases was condensed by attraction on the surface of the metal. William Charles Henry in 1836 and de la Rive in 1838 had proposed a chemical theory that intermediate compounds, for example, oxides of metals, were formed and decomposed. Sabatier soon proved that the specific action of catalysts strongly supports the chemical theory. He showed that different contact masses produce different reactions. Formic acid vapour passed over heated zinc oxide gives only hydrogen and carbon dioxide, but when passed over heated titanium oxide it gives only steam and carbon monoxide. Chromic oxide can act both in oxidation and in dehydrogenation and dehydration reactions. Heated alumina decomposes alcohol into ethylene and steam, metallic molybdenum and zinc oxide decompose it into acetaldehyde and hydrogen. Sabatier postulated the formation of different intermediate compounds, each with its own mode of decomposition, and he also clearly recognized that some organic reactions are reversible; and in cases where intermediate compounds cannot be isolated, there may be a production of surface compounds (chemisorption), thus linking the two theories of catalysis, the physical and chemical. Recent work has largely confirmed his views.

Sabatier's catalytic hydrogenation technique, carried out with relatively simple apparatus, was applied to the preparation of a large number of organic compounds. He clearly saw the technical importance of his work and took out several patents; but for some reason he did not extend the method to hydrogenation in the liquid phase. This was first studied by Ipatiev and led to a revolution in the fat industry by the hydrogenation of oils with a nickel catalyst.

Sabatier was responsible for opening out a new field in organic chemistry, and his clear appreciation of the importance of physical and inorganic chemistry in that branch of the science was most fruitful. The influence of his great master, Berthelot, with his wide interests, was clearly apparent in all Sabatier's work, and infused new life into organic chemistry at a time when it was becoming stereotyped.

Sabatier's personal qualities were greatly appreciated by his colleagues. Although able to lecture only in French, he was always welcome abroad. He was one of the great school of French chemists, and his contributions to the science were both extensive and important. The centenary of his birth was marked by commemorative meetings held in Toulouse during November 4–5.

OBITUARIES

Mr. J. P. Bushe-Fox, C.B.E.

JOCELYN PLUNKET BUSHE-FOX died on October 15 at the age of seventy-four, having been ailing for some time and unable to take part in archæological affairs. Archæology had been his great interest in life and the subject of his life-work. His education at St. Paul's School, with its fine classical tradition, influenced his choice of field, and it was to Romano-British archæology that he turned, after a brief interlude in Egypt.

He was one of the ablest of the young men whom Haverfield gathered about him for the initial exploration of the Roman site at Corbridge, Northumberland, and, strongly influenced by the then recent work of James Curle at Newstead, he began the study of stratified pottery of all kinds as a criterion for dating the sites upon which it was found. His Corbridge contribution was not so weighty as those which came later, but it still remains of value to students of the site and subject.

Under the ægis of the Society of Antiquaries, his excavation of two Iron-Age sites, at Swarling and Hengistbury Head, and of the Roman town at Wroxeter (*Viroconium*), laid foundations which have often been obscured by the important superstructures built upon them and have never failed. His work has stood the test of time and the challenge of later developments remarkably well.

His largest task, however, was undertaken after the First World War, in which he served with the distinction and ability of one who came of Irish military stock. He entered the Ancient Monuments Department of H.M. Office of Works (now the Ministry of Works) and undertook on behalf of the Society of Antiquaries the excavation of the Roman site at Richborough. This was a task of unprecedented complication, involving many levels often heavily robbed. The main lines of the history of the place were sorted out in four brilliant reports, in which the most notable feature, in what may appropriately be called the Bushe-Fox tradition, was the meticulous care devoted to the stratified pottery and small objects. Structurally, the most notable achievements were the definition of the great triumphal monument and of the supply-base which preceded it and occupied the Claudian invasion bridge-head.

No other worker has nine research reports of the Society of Antiquaries to his credit; no other perhaps the genial patience and scholarly perseverance to produce their like. They mark an age, and a standard of individual effort which deserves record, admiration and respect. I. A. RICHMOND

Dr. Anthony L. Levy

ANTHONY LEWIS LEVY lost his life on August 21, in a mountaineering accident on Mt. Olympus in the State of Washington, after he had successfully rescued an injured companion from a glacial crevasse.

Born in Romford, Essex, in 1924, Levy attended Brentwood Grammar School, Essex, and the Imperial College of Science and Technology, London, receivin his B.Sc. in 1944 and his doctorate in 1947. During the Second World War he worked on the chemistry of penicillin, research which led him to the development of methods for the stepwise degradation and synthesis of peptides. After the War, he continued his research at the Imperial College, London, under the direction of Sir Ian Heilbron and Dr. A. H. Cook, and in 1949 he was awarded a Rockefeller Foundation fellowship to work under Prof. K. Linderstrøm-Lang at the Carlsberg Laboratories, Copenhagen. From 1951 until his death he was an invaluable member of the Hormone Research Laboratory at the University of California, Berkeley. During this period, he developed a new solvent system for the two-dimensional chromatography of amino-acids on buffered papers, which has been widely adopted. His recent discovery of a new method for the quantitative microanalysis of amino-acids in proteins and peptides represents an outstanding advance in the field, and had already gained him world-wide recognition. Just before his death, he was engaged in research involving the structure and possible synthesis of adrenocorticotrophic hormone.

His former teacher, Sir Ian Heilbron, in a letter of sympathy to Levy's mother, wrote, "His most recent work was quite outstandingly brilliant, and Science, the world over, is the poorer by his passing". But the loss of this young biochemist is measured in terms not only of science, but also of humanity. His quick enthusiasm, his zest for life, and his warm generosity established him firmly in the affections of all who knew him, and he is sincerely mourned by all his colleagues and friends.

C. H. Li

NEWS and VIEWS

Jôkichi Takamine (1854–1922)

Jôkichi Takamine, the discoverer of the active principle in chemically pure form of the suprarenal glands, was born in Takaoka, Japan, a century ago on November 3, 1854. He was educated at Osaka, Kyoto and Tokyo and, after graduating in technology at the Imperial University of Japan in 1879, went with a government scholarship to the University of Glasgow, studying the chemistry of brewing at Anderson's College. On his return to Japan he was appointed chief of the Chemistry Division in the Department of Agriculture and Commerce, but resigned two years later to devote himself to industry. He developed the first superphosphate works in Japan, the Tokyo Artificial Fertilizer Company, and discovered the starch-digesting enzyme takadiastase. The remainder of his career was spent mainly in the United States where, in addition to his scientific activities, he wielded considerable political influence, being recognized as the unofficial representative of Japan. Joining Parke, Davis and Co., of Detroit and New York, in 1898, he began his search for the active principle of the suprarenal glands, a task which had been unsuccessfully attempted by some of the world's leading physiological chemists, and in 1901 he succeeded in obtaining adrenalin (as he called it) in stable and pure crystalline form. Takamine played a prominent part in developing Japanese industry and technical education and in establishing the Imperial Research Institute. A firm believer in the role of medicine as a civilizing force in Asiatic countries, he strove to promote better understanding between the country of his birth and that of his adoption. Recipient of many honours and a cultured, public-spirited and charming personality, Takamine died in New York City on July 22, 1922, at the age of sixty-eight.

Conference of Czechoslovak Archæologists

The "Ninth Working Conference of Czechoslovak Archæologists", organized in Prague during September 25–30 by the Czechoslovak Academy of Sciences, included visitors from Britain, East and West Germany, Hungary, Poland and the U.S.S.R., as well as Bohemia, Moravia and Slovakia, and the themes were treated from a general Central-European point of view. (Before 1945, Czech archæology had tended to be rather excessively Bohemian, partly of course because Moravia and Slovakia were far less well explored.) The central theme was the chronology of early Slav settlement, as determined largely by pottery. Poulík from Moravia opened with an able restatement of the traditional thesis of Pič, adjusted to accommodate the enormously augmented data, according to which early Slav pottery, and therefore its makers, is to be derived from the Lusatian urnfields of the Late Bronze Age. But this thesis was stringently criticized in a lively debate. The visitors were also able to see several early Slav oppida, excavated with superb technical skill so as to disclose the remarkable wooden constructions in their ramparts and the plans of wooden houses enclosed therein, as well as the encampment of mammoth hunters at Pavlov, near Dolni Věstonice, later in date than the classic Gravettian site, but, like it, yielding clear hut plans, a rich industry in flint, bone, antler and ivory (not distinctively Magdalenian in character) and interesting art objects. They also visited the new archæological institute established at Nitra by the Slovak Academy of Sciences; the institute is well equipped, and already stocked with a wealth of relics derived from scientific excavations in this rich metalliferous region that had previously been represented in the archæological record only by stray finds.

Rumford Bicentenary: Celebrations in Boston

The Rumford bicentennial issue of the *Proceedings of the American Academy of Sciences and Arts* (82, No. 7, 249; December 1953) is the complete record of the scientific and biographical papers presented at the symposium which marked the two hundredth anniversary of the birth of Benjamin Thompson, Count Rumford, and which was held at the Academy in Boston during March 26–28, 1953 (see *Nature*, 170, 954 (1952); 171, 538, 540 and 947 (1953)). In the introductory article by Harlow Shapley, chairman of the Rumford Bicentennial Committee, the celebrations are described and the illustrated bill of fare of the birthday banquet, which was compiled by Prof. Sanborn C. Brown, is reproduced. Prof. Brown also directed the preparation of the various models of the inventions and contrivances of Count Rumford which were on exhibit and delivered the Rumford Bicentennial Lecture, the text of which is included in the bicentennial issue and which also appears in

American Scientist (**42**, 113; January 1954). The texts of the speeches made at the presentations of the Rumford Medals to Peter Debye, Norman F. Ramsey and Lars Onsager follow, and then the papers delivered at the three symposia on recent developments in thermodynamics, in atomic spectroscopy and in nuclear physics. These include articles by P. W. Bridgman on thermodynamics, Sir Alfred Egerton on the management of flame, Sir Francis Simon on helium and the range of stability of the solid state, E. M. Purcell on line spectra in radio astronomy, M. Siegbahn on nuclear spectroscopy, and V. F. Weisskopf on phase transitions in atomic nuclei.

National Central Library: Report for 1953–54

The thirty-eighth annual report of the Executive Committee of the National Central Library, covering the year ended February 28, 1954 (pp. 28; from the Library, London), records an increase in the Treasury grant-in-aid from £31,250 to £32,000. In the reconstruction of the Library, of an expenditure of about £105,626, £95,495 had fallen on the War Damage Commission and the Board of Trade. The library stock increased during the year by 4,423 (of which 2,472 were by purchase) to about 141,000. Applications received for loans from or through the library decreased from 100,049 in 1952–53 to 93,653, of which 71·71 per cent were successfully handled (71·21 per cent in 1952–53); total issues were 95,626 volumes, of which 17,285 were to university libraries, 10,307 to special outlier libraries, 5,845 to government departments, 5,278 to industrial and research organizations, and 14,641 to adult classes, 10,658 of these last-named being issued through adult class organizations. In the regional library systems 395 municipal, 56 county, 20 university and 84 special libraries are now co-operating, and loans totalled 169,925 within the systems and 26,689 outside them. Taking the view that membership by every public and county library of a regional system is essential to the structure of national interlending, the Executive Committee has adopted the principle that no public or county library shall be able to use the inter-loan services of the Library except as a member of its appropriate regional system. Although loans to university libraries were 755 less than those of the previous year, 24,072 books were lent by university libraries compared with 23,905 in 1952–53. Loans to and from foreign libraries again increased: 2,531 volumes were lent to forty-one countries and 1,158 borrowed from nineteen countries, France continuing to be the only country lending considerably more than it borrows and coming second to Germany as a lender of books to Britain. The Outlier Union Catalogue of books expanded faster than in recent years, and considerable progress was made in compiling the Union Catalogue of printed material in the Russian language in the libraries of the United Kingdom.

Social Problems of Handicapped Children

According to official estimates, there must be between 350,000 and 500,000 handicapped children of school age in England and Wales. All these children require special education or treatment because of some mental or physical disability. Partly because there is no awareness of the size of the problem, few members of the general public realize the difficulties that have to be faced by these children and their parents. They do not know that there are many active voluntary organizations working in this field, while even these organizations themselves are sometimes unaware that their good work is perhaps being duplicated somewhere else. To present the problem of handicapped children as a whole, Mrs. Peggy Jay has written a pamphlet called "Making our Way", which is published by the National Committee for the Defence of Children, London (pp. 12; 1954; 6*d*.). Copies can be obtained from Dr. Simon Yudkin, 23 Tillingbourne Gardens, London, N.3). The booklet shows how much has still to be done before every handicapped child can be said to be receiving all the medical attention and special education that will enable it to develop as fully and happily as its disability will allow.

Australian and New Zealand Association for the Advancement of Science: Brisbane Meeting

The report of the twenty-eighth meeting of the Australian and New Zealand Association for the Advancement of Science, held in Brisbane in May 1951, has only recently been received (Vol. 28; pp. 199. Brisbane: Government Printer, 1951). Besides Sir Kerr Grant's presidential address, "Old Questions and New Answers—Men Who Found Them", in which he reviews the contributions of Einstein, Minkowski, Planck, Rutherford, Bohr and Eddington to the concepts of space, time and atomic structure, it includes the presidential addresses to Sections, Dr. D. P. Mellor's Liversidge lecture, "Some Recent Developments in the Chemistry of Metal Complexes", and the addresses given by a Unesco delegation, which included Dr. E. B. Ford and Prof. C. H. Waddington, at two symposia on evolution. The longest of these latter addresses is that by Dr. Ford on the experimental study of evolution. Most of the presidential addresses are concerned with aspects of science of particular interest in Australia and New Zealand, though not necessarily to the extent of the review of Australian plant products given by Dr. L. H. Briggs to the Chemistry Section. Those of Dr. E. R. Walker on economic science and public policy, H. T. Parker on the scientific approach to the problems of teaching, Dr. B. J. Grieve on viruses and physiology of the host plant, Prof. R. H. Thorp on modern pharmacology and its influence on medicine and pharmacy, Dr. R. M. C. Gunn on cyclic changes in spermatogenesis in rams, and Dr. F. C. Courtice on extravascular protein and the lymphatics are at least of equal interest to scientific workers elsewhere. It is unfortunate, however, that there is not uniformity in format from year to year in reference volumes of such merit: the present volume is quarto, whereas the succeeding volume reverts to octavo. The inconvenience to the librarian and other users is obvious.

Rice Breeding and Genetics

In a monograph under the above title, K. Ramiah and M. B. V. N. Rao have given a comprehensive account of the rice plant and its utilization in India and elsewhere (Sci. Monograph No. 19, Indian Counc. Agric. Res.; pp. 360; 1953; Rs. 17.8 or 27*s*.). Although the central feature and aim of the monograph is to deal thoroughly with the breeding, genetics and cytology of rice, and to review in detail all relevant information, this volume also contains much of more general interest in that it touches upon such topics as the origin, antiquity and taxonomy of rice, the wild races and species, their botany and development, and so on. Special chapters are devoted to the application of genetics to the improvement of the crop, methods of selection, and agricultural aspects and prospects in India. A very large section of the monograph is devoted to the genetics of rice, the inheritance of pigmentation, morphological, physiological and quantitative characters, correlations, linkage, mutations and cytology, each receiving detailed treatment. The factor of quality, as befits its importance, is discussed in its several aspects. The central aim of all this work is, of course, to improve rice production in a region where it is virtually the staple food. Here the authors make comparisons with rice production in other large-producing countries, especially those in which high yields are obtained, and conclude that much can be achieved in India by the appropriate use of fertilizers. "That India has not been able to increase her production substantially is certainly not due to lack of experimental research or scientific knowledge. The most significant reason appears to be the wide gap between research and extension. The cultivator does appreciate the value of scientific knowledge but still he cannot make use of it." The monograph is well illustrated, with some good coloured plates.

Seismology in New Zealand during 1951–53

THE readings of seismograms obtained at thirteen New Zealand observatories (including Suva, Fiji) for the periods January–March and April–June 1951 have been published for the Geophysics Division of the New Zealand Department of Scientific and Industrial Research (pp. 16 and 13, respectively. Wellington: Government Printer, 1953). Earthquake epicentres follow a familiar pattern, as they also do for 1952. In the publication dealing with "Earthquake Origins in New Zealand during 1952" (Seism. Obs. Bull., *S*-98 ; pp. 4+1 map. Wellington: Government Printer, 1953) it is stated that most of the epicentres in 1952 lay between latitudes 37° and 43° S., and there were no epicentres north-west of Karapiro. Isoseismal lines are given for the earthquake of August 28, 1952, with epicentre near Havelock North (greatest intensity, 6 +). The provisional seismological bulletins for July and August 1953 show that the greatest local earthquakes, on July 4 and August 1, both had instrumental magnitude 5·3. The former affected central and western parts of North Island (Tokaanu region), and the latter had an epicentre near lat. 44·8° S., long. 175·8° W.

Museum of Applied Arts and Sciences, Sydney: Report for 1953

THE annual report for 1953 of the Museum of Applied Arts and Sciences, Sydney (pp. 14; published by the Museum, 1954), records the activities of this well-known institution under the energetic directorship of Mr. A. R. Penfold. Although the display side of the Museum is by no means neglected—such exhibits as one demonstrating the energy released by an atomic blast and another of a working compound condensing engine and boiler under steam bear ample witness to this—an impressive amount of scientific work has been accomplished. Such subjects as the establishment of plantations of commercially valuable eucalypts and tea trees in Australia, the effect of modern synthetic fibres on the Australian wool industry, and technical advice concerning paints and varnishes are an indication of the practical use to the nation of the resources of this Museum.

Swedish Physics Conference of September 1952

THE sixth general physics conference of the Swedish National Committee for Physics was held in Stockholm during September 25–27, 1952. As it took place at the same time as the international instruments and measurements conference and exhibition, those attending the physics conference were able to participate in the sessions of the instruments conference, and members of the instruments conference in two of the sessions of the physics conference. The guest lecturers were Prof. E. Bak and Mr. J. R. Anderson, who spoke on microwave spectroscopy and special microwave measurements; Prof. E. Laurila on measuring instruments employing feed-back; and Prof. S. Westin on a new electric calculating machine and on geotechnical measurements with strain gauges. The secretary of the physics conference was Dr. Sven Benner, of the Radiophysics Laboratory at the King Gustav V Jubilee Clinic, Gothenburg. Short summaries of the other papers presented to the conference are printed in the January number of *Arkiv for Fysik* (7, 73; 1954).

Survey of Field Theory: Physical Society Meeting in Birmingham

THE autumn meeting of the Physical Society will be held in the Poynting Physics Building, University of Birmingham, during December 13–14, the subject being "A Survey of Field Theory". The meeting, which is being organized by Prof. R. E. Peierls, will consist of series of lectures on the interactions between mesons, nucleons, photons and electrons, and, since no specialist knowledge will be assumed, it is hoped that they will be suitable for experimentalists with a general knowledge of quantum mechanics and for theoreticians who do not specialize in field theory. Prof. Peierls will both give an introduction to the proceedings and sum up at the end. The papers will be as follows: fields and particles, by Dr. P. T. Matthews (Birmingham); interactions between fields, by Dr. A. Salam (Cambridge); the state of knowledge of the properties of π-mesons, by Dr. P. T. Matthews (Birmingham); and phenomena involving mesons and nucleons at high energy, by Dr. G. Feldman (Birmingham). Those who are not members of the Physical Society may attend, on completing an application form obtainable from the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

University of Leeds

THE following appointments have been made in the University of Leeds: A. Richardson, lecturer in the Department of Electrical Engineering; Dr. J. H. Robertson, Brotherton lecturer in the Department of Inorganic and Structural Chemistry; Dr. P. Feltham and Dr. R. Shuttleworth, lecturers in metallurgy in the Department of Coal Gas and Fuel Industries with Metallurgy and Chemical Engineering; D. Payne, lecturer in agricultural chemistry; and Dr. D. Dowson, lecturer in the Department of Mechanical Engineering. The title of emeritus professor has been conferred on Prof. J. W. Harvey, on his retirement from the chair of philosophy, and on Prof. A. N. Shimmin, on his retirement from the chair of social studies. Recent gifts to the University include the following: £3,900 over three years to the Department of Botany from the Nuffield Foundation for research under the direction of Prof. R. D. Preston on the molecular structure of the cell walls of plants; £1,000 a year for two years to the

Department of Colour Chemistry and Dyeing from the Bradford Dyers' Research Association, this being a renewal of a grant for a research fellowship; a recurrent grant of £800 a year to the Department of Experimental Pathology and Cancer Research from the Medical Research Council for research into the possible carcinogenic fractions from tobacco tar; £3,000 to the Department of Mining from the North-eastern Division of the National Coal Board, this being a renewal of the annual grant, and £3,475 from the National Coal Board for special research projects in the Department; £2,000 to the Department of Psychology from the Department of Scientific and Industrial Research for a research project on the comprehensibility of technical reports; £1,100 a year for two years to the Department of Textile Industries from the Bradford Dyers' Association, Ltd., this being a renewal of a grant for a research fellowship, and £450 a year for seven years from the Dunlop Rubber Co., Ltd., London, for a research scholarship.

Institution of Naval Architects: Scholarships

THE Institution of Naval Architects has made the following awards for 1954: Institution of Naval Architects Scholarship in Naval Architecture to J. C. Sainsbury (H.M. Dockyard, Devonport); Vickers-Armstrongs Scholarship in Naval Architecture to A. R. Mountfield (Cammell Laird and Co., Birkenhead); and Yarrow Scholarship in Marine Engineering to G. W. Pinhey (H.M. Dockyard, Devonport). The scholarships are tenable for three years, the Vickers-Armstrongs one being worth £220 a year and the other two £175 a year. In each case the recipient has elected to study at King's College (University of Durham), Newcastle upon Tyne.

Royal Society of Edinburgh

THE following have been elected office-bearers and members of council of the Royal Society of Edinburgh: *President*, Prof. James Ritchie; *Vice-Presidents*, Prof. R. C. Garry, Prof. W. M. Smart, Dr. A. H. R. Goldie, Prof. C. M. Yonge, Prof. Norman Feather and Sir Godfrey Thomson; *General Secretary*, Dr. J. E. Richey; *Secretaries to Ordinary Meetings*, Dr. T. R. Bolam and Dr. D. M. Steven; *Treasurer*, A. W. Young; *Curator of Library and Museum*, Dr. Douglas Guthrie; *Councillors*, Dr. D. P. Cuthbertson, Principal H. B. Nisbet, Prof. T. C. Phemister, Dr. J. B. Simpson, Prof. Meirion Thomas, Dr. J. M. Cowan, Dr. David Jack, Prof. J. M. Robertson, Prof. D. Whitteridge, Prof. E. M. Wright, Prof. E. L. Hirst and Dr. D. E. Rutherford.

The Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: J. A. Spence (plant pathologist, British Guiana), plant pathologist, Trinidad; A. C. Ellington (senior scientific officer, Government Chemists' Department, Jamaica), assistant government chemist, Government Chemist's Department, Jamaica; J. E. Ho-Yen (senior assistant government analyst, British Guiana), government analyst, British Guiana; R. M. Lawton (assistant conservator of forests, Gold Coast), assistant conservator of forests, Northern Rhodesia; Dr. G. M. Edington and Dr. M. H. Hughes (pathologists, Gold Coast), specialist pathologists, Gold Coast; P. H. Creutzberg and J. C. D. Watts (scientific officers, Sierra Leone), senior scientific officers, Sierra Leone; K. W. Aspinall (veterinary officer, Tanganyika), deputy director of veterinary services, Nyasaland; W. J. Gray (veterinary officer, Nyasaland), veterinary officer, Northern Rhodesia; J. McCulloch (principal veterinary officer, Eastern Region, Nigeria), deputy director of veterinary services, Northern Region, Nigeria; L. E. McLaren (veterinary officer, Jamaica), senior veterinary officer, Jamaica; G. C. Billington (assistant statistician, Gold Coast), senior statistician, Gold Coast; W. L. Booker and J. M. Simmonds (assistant statisticians, Gold Coast), statisticians, Gold Coast; St. G. C. Cooper (agricultural superintendent, Dominica), senior agricultural officer, Trinidad; J. W. Drummond and J. L. Maxwell, agricultural officers, Nyasaland; D. Jack, agricultural officer, Tanganyika; R. J. Jones, D. Juckes and J. Morrison, agricultural officers, Kenya; D. R. Mackay, agricultural officer, Northern Rhodesia; R. L. Morris, agricultural officer, Sierra Leone; J. A. Palmer, agricultural officer, Fiji; R. T. Cannon, R. A. Dujardin and D. G. Price, geologists, British Guiana; C. R. Jones, geologist, Federation of Malaya; D. M. Langbridge, scientific officer, Nigeria; R. H. Ansell, veterinary research officer, Kenya; H. J. Burgess, timber research officer, Federation of Malaya; L. G. Campbell, agricultural engineer, Trinidad; K. Klimacki, geologist, Water Development Department, Tanganyika; D. N. McNutt, entomologist, Kenya; J. R. Sterry, agricultural officer, Gold Coast; B. H. Wyatt, research assistant, Department of Tsetse Control, Gold Coast.

Announcements

WE regret to announce the following deaths:

Sir Wallace Akers, C.B.E., F.R.S., lately director of research, Imperial Chemical Industries, Ltd., on November 1, aged sixty-six.

Sir John Lennard-Jones, K.B.E., F.R.S., principal of the University College of North Staffordshire, on November 1, aged sixty.

AT the invitation of the Council of the Royal Society of Edinburgh, Prof. James Kendall, the immediate past president of the Society, will deliver the first Alembic Club Lecture of the Society, on January 10, 1955, his subject being "Michael Faraday".

PROF. K. MOTHES, of the University of Halle and of the Institute of Plant Culture Research, Gatersleben, of the German Academy of Sciences, has been elected president of the German Leopoldina Academy of Natural Sciences, Halle. Prof. Mothes is a member of the Botany Section of the Academy.

A Tin Research Institute Fellowship has been established at University College, London, and Mr. R. H. Prince has been appointed as the first holder. He will work under the supervision of Prof. E. D. Hughes on certain aspects of the chemistry of organotin compounds.

THE Technical Publishing Society, a professional group for the encouragement of the interchange of information among those preparing, editing or publishing technical and scientific documents, has been organized in Los Angeles, with A. E. Tyler, of the United States Naval Ordnance Test Station, Pasadena, as president. Membership includes editors, writers, illustrators, management and production personnel from industrial and government research and development laboratories. Further information can be obtained from the secretary-treasurer, William E. Welch, P.O. Box 607, Tarzana (Los Angeles County), Calif.

ADULT EDUCATION IN GREAT BRITAIN

REPORT OF THE ASHBY COMMITTEE

THE Committee appointed by the Minister of Education in June 1953, under the chairmanship of Dr. Eric Ashby, to consider the organization and finance of adult education in England and Wales, has now presented a unanimous report[*] which is of wide interest. It includes a concise, coherent account of previous inquiries into adult education and of the regulations which govern its administration. A summary is provided of the written and oral evidence submitted to the Committee, while there are appended, *inter alia*, copies of the resolution sent by the Trades Union Congress to the Prime Minister and Miss Horsbrugh in February 1953 and Sir Winston's reply, in which he stated his belief that "there is, perhaps, no branch of our vast educational system which should more attract within its particular sphere the aid and encouragement of the State than adult education".

It is clear from the report that the Ashby Committee was not asked to examine an organization which had broken down or lost its purpose. It heard no evidence which suggested that the present administrative arrangements are gravely unsatisfactory; indeed, the whole range of evidence, from Sir Winston's letter just quoted to the testimony of those engaged in teaching adult students, was unanimous in the assumption that liberal adult education is still essential. Such changes as the raising of the school-leaving age, the increased provision for secondary education, university expansion and increased assistance given to university students, the development of the cinema, broadcasting and television in a period of full employment have affected adult education, and its content and pattern must change with changing times. No one engaged in adult education, however, is so perturbed by these developments as to question the desirability of the work in which he is engaged, and at the most modest estimate adult education in its present framework serves a purpose which no other agency or activity fulfils.

There are indeed no signs that adult education as an organized activity has, or will become, either universal or lifelong. Out of 31 million adults in England and Wales, only some 150,000 attend adult education classes; but the Ashby Committee believes it to be broadly true that, in relation to the community at large, adult education students represent a social and intellectual asset the loss of which would be deplorable, and it records the hope that the genuine educational desire of such students will never go unfulfilled through lack of funds. This is not to say that the organization and provision of adult education could not be improved, or that its purposes and methods should not be readjusted to meet the needs of contemporary society. Nevertheless, it found no evidence that overlapping is a serious problem in the present system, which is essentially a partnership between the Ministry, universities, voluntary bodies and the local education authorities, with the drawbacks of administrative complexities as well as the mutual advantages which such a system involves. These advantages, however—not merely the enriching of adult education by the partnership of the universities, the voluntary bodies, the local education authorities, and the Ministry, but the enriching of the partners, too—are regarded as so important that, in this period of transition in British education, the Committee recommends they should be preserved. Disclaiming at this juncture any intention to set a course for adult education over the rest of this century, the Committee's advice is essentially to leave well alone.

Some changes indeed are suggested, but the arguments on which the Committee's recommendations are based are perhaps of wider interest than the detailed recommendations. The Committee pays tribute to the labours of the Workers' Educational Association and is unanimous that 'voluntary-ism' as exemplified by the Association is essential to the preservation of the spirit of adult education. Nevertheless, it believes that the future of the Workers' Educational Association will not be secure unless it can resolve its internal conflicts as to the direction and scope of its activity, and translate its decisions into executive action appropriate to its districts.

Of the universities and university colleges, on which has fallen the main burden for providing liberal adult education in England and Wales, the Committee remarks that the high regard which the public has for British universities is due partly to the fact that through their extra-mural departments they have kept close to the people of Britain. It is evident that many universities set a high value on extra-mural work for its own sake, both for this reason and as a duty which scholars owe to their fellow-citizens. There was great diversity of opinion in the evidence from extra-mural departments and the governing bodies of universities, but there was no dispute that universities should continue to take a large share in responsibility for liberal adult education and on no account surrender that responsibility to local education authorities; that full-time extra-mural tutors should be 'assimilated' in salary and status with the rest of the academic staffs; and that student fees should be determined locally and (in general) should not be increased.

While appreciating the traditional prestige and the real value of the longer course, and especially of the three-year tutorial class, the Committee thinks it undesirable from every point of view that university participation in adult education should be restricted to the provision of three-year tutorial and sessional classes. It did not, however, accept the argument that all adult teaching which is done by a university teacher is of 'university standard', and it considered that an extra-mural department which contemplates the provision of a particular course should satisfy itself that the course is one which can properly be given as part of the university contribution to adult education. In the current man-power situation, the caution against the regular employment of university teachers in providing elementary routine courses is timely, and it is coupled with an invitation to the extra-mural departments to consider whether their resources would not be most usefully employed if, in certain directions, they imposed something of a self-denying ordinance upon themselves.

---

[*] Ministry of Education. The Organization and Finance of Adult Education in England and Wales. Report of the Committee appointed by the Minister of Education in June 1953. Pp. iv+67. (London: H.M. Stationery Office, 1954.) 2s. 6d. net.

On all grounds, and in agreement with the great majority of universities, the Committee thinks it would be undesirable for the Ministry to withdraw its direct grants to the universities for adult education, and for the whole financial responsibility to lie with the universities. It sees danger in maintaining extra-mural work indefinitely as a 'protected' activity in universities: adult education, it is observed, will never become an accepted part of university work in the sense that dentistry or psychology is accepted, unless it establishes its right to a share of the university's finances, but it does not consider that this is the occasion to precipitate the fight for recognition. The suggestion of the Association of Education Committees that the University Grants Committee should make itself responsible for financing all extramural work done by universities and that local education authorities should be responsible for financing the provision of all the rest is rejected, because of the weakening effect the proposal might have on voluntary effort and the risk of uneven interpretation. The Committee recommends that the Ministry should not only continue to give direct grants to the bodies responsible for adult education but also should be prepared to exercise on occasion a more active and flexible control of expenditure.

The Committee stresses the importance of this flexibility, which it would not merely preserve but even increase. The present diversity of pattern in the provision of adult education is regarded as an advantage: there is no evidence that it causes appreciable overlapping or extravagance in expenditure; and a uniform pattern, though it might appear efficient on paper, would suffer from all the inefficiencies of a system which takes no account of local differences. Accordingly, the Committee recommends that the present method of fixing grant ceilings on the basis of grant carried in the year when expansion was checked should be discarded. In its place a system should be adopted under which allocations representing the maximum amount of grant available to each responsible body for the coming year should be made after consideration of the quality and standards of work being done by that body, as well as its proposed programme, the needs of the region in which it operates, and the activities of other interested bodies in the region. The limits on the salaries of full-time tutors recognized for grant should be removed, although responsible bodies should still be required to obtain the Ministry's approval for new full-time appointments on which grant would be sought. It would also raise the level up to which fees of part-time tutors are recognized for grant, and in the calculation of grant the conception of sessional rates of payment for part-time tutors of tutorial classes should be replaced by rates of payment by the hour or by the meeting.

The Committee also recommends the amendment of Further Education Grant Regulations so as to give less prominence to the length of course as compared with other criteria. Classes for special groups of students should be acceptable for grant provided the enrolment of other students is not unreasonably prohibited and the Committee would not exclude courses of high quality from grant on the grounds of vocational interest. It recommends that responsible bodies should be given some assurance that the total allocation of grant for adult education should not be reduced at short notice. It would widen the interpretation of teaching costs to include, besides the primary responsibility of teaching costs, such work as responsibility for a library service or giving guidance to junior colleagues. Local conditions should be the primary consideration in fixing student fees. Such fees should be kept under review and raised if local conditions justified and necessitated this action; and both the Minister and local education authorities in determining their grants should take into account the total financial contribution being made by the students.

As regards the content of courses, the Ashby Committee thinks that money is well spent in satisfying a genuine demand from students who are prepared to throw themselves whole-heartedly into the work of the class; but that public money should not be spent on titillating the interest of students who are not prepared to make some sacrifice of their own time and effort to work at the subject of the class. As regards the content of the subject taught, the Committee would be sorry to see a list of approved subjects drawn up, because it would soon become obsolete and its very existence would discourage fresh ideas. This is a main reason for the suggestion that the Minister should establish a small committee to advise from time to time on the subjects and types of adult education courses which should receive priority in qualifying for grant.

The Ashby Committee's report, for all the merit of the minor improvements it recommends, is probably of most value as a stimulus to the constructive thinking which not only such a Committee but also the responsible bodies, local authorities and others should be giving to the scope, the functions and content of adult education in our changing social pattern.

THE PHYSICS OF THE IONOSPHERE

THE Physical Society held a Conference at the Cavendish Laboratory, Cambridge, during September 6–9, on "The Physics of the Ionosphere". It was attended by about 150 delegates, many of them from overseas. The subjects discussed were: the lowest ionosphere; irregularities and horizontal movements in the ionosphere; the *F*2-layer; the mathematics of wave-propagation through the ionosphere. Under each of these headings a paper was read which summarized the existing background of knowledge against which the discussion could take place. In the discussion itself short prepared contributions, which had previously been circulated in print, were first presented, and were followed by a general discussion on special problems. Most of the contributions to the prepared discussion will be published as full-length papers in a report on the Conference (available from the Secretary-Editor, Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7). Some of the more interesting points emerging from the Conference are mentioned below.

D. F. Martyn presented the latest stage of his work on movements in the *F*-layer. He first pointed out that, when Hall effects are taken into account, in a modification of Schuster's theory of the atmospheric dynamo, the electrostatic polarization in the dynamo region is different from that deduced originally by Schuster. The fields produced, in the F-layer, by this polarization in the dynamo region would explain the major vertical and horizontal movements of that layer. Finer detail can be explained in terms of diffusion if the air density in the F-region is as small as seems to be indicated by recent rocket measurements. This latest stage of Martyn's work seems to bring us near the proper explanation of most problems of movement in the F-layer.

Delegates to the Conference were fortunate in hearing the first account of some of the scientific results which have resulted from a study of the forward scattering of 50 Mc./s. waves from the ionosphere. D. K. Bailey surveyed evidence which suggests that this scattering occurs at heights between 75 and 90 km. The height and the intensity of the scattering vary with season and with time of day. Preliminary results concerning the resultant distribution of signal amplitude over the ground were presented, both in terms of the speed of fading and of the auto-correlation function in distance. It is certain that these results, accumulated in the United States over a period of several years, will be of great importance for ionospheric theory; it is too early yet to try to assess their significance in detail.

The workers at the Naval Research Laboratory, Washington, led by E. O. Hulburt, one of the earliest ionospheric physicists, presented some most interesting and stimulating suggestions about the formation of the ionized layers. Measurements made recently with rockets were quoted to support the suggestion that both the E- and the F-layers are produced by X-rays and that, although the D-region is mainly ionized by ultra-violet light (Lyman α), the extra ionization at times of sudden ionospheric disturbances is produced by X-rays.

The absorption of waves of frequency between 2 and 4 Mc./s. was discussed, and the widespread belief that it could mostly be accounted for by D-region absorption, obeying the frequency law appropriate to a non-deviating region, was questioned. The majority of the workers on this subject were represented at the Conference and they had some fruitful discussion, without reaching any agreement. It was, at any rate, realized that the matter is still open to question.

Observations of echoes returned at vertical incidence from heights between 80 and 100 km. on frequencies near 1 Mc./s. were described. There was disagreement about whether the echoes represent total reflexion from an over-dense layer, partial reflexion from a sharp gradient of electron density, or scattering from irregularities.

Several new results were reported concerning irregularities and horizontal movements in the ionosphere. S. A. Bowhill suggested that in the lowest part of the ionosphere the irregularities of electron density have two sizes, a larger one low down and a smaller one higher up, and that the way in which the fading speed varies when the radio-frequency is changed from 16 to 2,400 kc./s. can be explained in terms of them. He also suggested that the mean drift-velocity of the larger irregularities is smaller than their random velocities, whereas the opposite is true for the smaller irregularities.

A consideration of the amplitude of successive echoes reflected from the E-layer on a frequency of 150 kc./s. led R. L. Schrag to suggest that, at night, the layer sometimes acts like a concave mirror and produces a focusing of the waves returned to the earth. This appears to be the first time that focusing has been noticed from the E-layer, although it is a well-known phenomenon with F-layer echoes.

J. L. Pawsey mentioned that workers at the Radio Physics Laboratory in Sydney had noticed ionospheric focusing of the radiation from radio stars received at shallow angles. It was not certain whether the focusing was produced in the E- or the F-layer. Evidence was presented to show that, on the average, the shape of the ionospheric 'lenses' is not circular.

It was emphasized that all radio methods measure the movements of irregularities of electron density, and that these are not necessarily the same as the movements of the air or even of the surrounding electrons. It is therefore important that the subject should not be confused by describing these movements as 'winds'; they could more precisely be called 'drifts'. In this connexion, P. C. Clemmow, K. Weekes and M. A. Johnson presented a paper which showed that a cylinder of enhanced ionization, immersed in a background of ionization, in the presence of a magnetic field would move in a direction which depended on the collision frequency of the electrons and might be different from the direction of motion of the surrounding ions.

Several speakers dealt with the question of the distortion of the F-layer at times of ionosphere disturbance. Sir Edward Appleton and W. R. Piggott suggested that the effects of disturbances depend on the epoch in the sunspot cycle, and that there is a difference between the rising and the falling parts of the cycle. S. Matsushita, and R. W. Wright and N. J. Skinner discussed the effects of disturbances in the equatorial zone.

It was frequently mentioned that, although a very great effort is put into obtaining ionospheric $h'(f)$ records from all over the world, the amount of information available from them, for purposes of ionospheric physics, is not as great as it might be. Several speakers discussed how the height distribution of electrons could be deduced from the records. The main emphasis was on the shortening of the computations and the inclusion of the effect of the earth's magnetic field. It appeared that the required computations could be carried out, with comparatively little labour, so as to indicate the state of the ionosphere at one place on an average magnetically quiet day in any month, and the hope was expressed that an organization might be set up to perform computations of this kind for the observations from a few selected sites during the forthcoming Geophysical Year.

In the part of the Conference dealing with mathematics, the discussion centred, as was intended, on mathematical methods rather than on the results obtained. A series of papers dealt with the problem of tracing rays through the ionosphere in the presence of the earth's magnetic field. This problem was solved, in principle, several years ago. The new work is concerned with methods which are sufficiently rapid for practical application, and some of them seem to be promising in this respect. If these can be brought into routine use, there will be considerable improvement in the calculations of maximum usable frequencies.

Other mathematical papers dealt with the coupling of the characteristic waves in the ionosphere, and with the detailed statistics of the collisions of electrons with heavy particles and its bearing on magneto-ionic theory.

The Physical Society is to be congratulated on arranging such a successful conference at a time when a large proportion of those actually engaged in ionospheric research could be present. The publication of the report, which is promised soon, will add considerably to the value of the Conference.

CARBON-14 DATING

SYMPOSIUM IN COPENHAGEN, SEPTEMBER 1–4

It is now generally recognized that the method of dating organic material by assay of radiocarbon content is of outstanding promise for many sciences, particularly archæology and the aggregate of archæology, geology and biological sciences which can be called 'Quaternary research'. The demonstration of its feasibility by W. F. Libby was followed by the initiation of many projects for radiocarbon dating, centred in North America and in Europe. Those most concerned in North America have already had more than one joint meeting, but European workers have remained relatively isolated from one another until this year, when they attended an informal symposium in Copenhagen.

The meeting was sponsored by the Danish Rask–Ørsted Foundation, and was actively supported by the organizing committee of the Copenhagen carbon-14 project which has been operating since 1951 under the chairmanship of Dr. Therkel Mathiassen. The secretary of the meeting was Dr. Hilde Levi, head of the Copenhagen carbon-14 dating laboratory, and, through her, invitations were sent to the several European centres known to have carbon-dating plant working or under construction: two or three members attended from each centre.

The first day's discussion opened with consideration of technical matters associated with solid-carbon counting by methods essentially those of W. F. Libby, as now being used in Copenhagen and in Rome, and in preparation at Trondheim and Stockholm. This was followed by accounts of the processes being worked out for the use of gas-counters with the carbon in the form of carbon dioxide (Groningen and Heidelberg), acetylene (Royal Institution, British Museum and Harwell jointly, and Cambridge), and methane (Goteborg). Many interesting aspects of the production of the counting gases were considered, more particularly the hydrocarbons.

It became perfectly clear that gas-counting both by carbon dioxide and by acetylene is more expeditious and somewhat more sensitive than screen-wall counting of elemental carbon, and may be expected to displace the older method, which nevertheless is now producing a large part of the published datings. Only brief reference was made to scintillation counting.

Discussion on the third day concerned sources of error inherent in the samples and the techniques, and precautions which they involve, and some brief consideration of datings secured by European projects. It was apparent that, while cross-checking of samples could usefully be considered in this way, the implications of several unpublished datings were far too wide for the limited personnel and time of the meeting.

Some consideration was given to the standardization of form of publishing results, and to dating projects requiring international organization. It was agreed that a second symposium ought to be held, at least to deal with technical advances, within the next year or so and that *rapprochement* should be sought with American colleagues.

This first meeting proved extraordinarily profitable to all participants, not least because of the close personal discussions made possible by its small size and informal nature. The hospitality of our many Danish hosts and the skill and tact of Dr. Levi in organizing the meeting were beyond praise.

HYDERABAD CENTRAL LABORATORIES FOR SCIENTIFIC AND INDUSTRIAL RESEARCH

REPORT FOR 1952

The annual report for 1952 of the Central Laboratories for Scientific and Industrial Research, Hyderabad*, which has only recently been published, refers to the slow progress of the new building, towards the completion of which the Government of India sanctioned a non-recurring grant of 5 lakhs of rupees. Research in the Oils and Entomology Sections during the year included the preparation of insecticidal material from sitaphal seed and soap-making trials of sitaphal oil, the dehydration of castor oil, continuous preparation of triricinolein, indigenous cotton-seeds and their oils, separation of fatty mixtures and the antioxidant properties of aca-catechin. The Fibre and Paper Section examined the possibilities of manufacturing filter and board paper from tailor wastes and of using casuarina wood pulp as a diluent for cotton-seed linters. The Fuel Section made a rapid survey of the distribution, classification and available reserves of Hyderabad coals and continued its systematic physical and chemical survey. A pilot-plant investigation of the briquetting of non-caking coals has been undertaken and, in connexion with the installation of the Lurgi low-temperature carbonization plant, the weathering properties of Hyderabad coal and its oxidation in a fluidized bed, the recovery of tar acids and hydrocarbons from low-temperature tar and of benzole from carbonization gas are being studied.

The Heavy Chemicals and Fertilizers Section has been concerned with the utilization of felspar and iron pyrites, and of sulphates for the manufacture of sulphuric acid as well as the preparation of activated charcoal from groundnut hulls. A systematic study of Hyderabad clays was made in the Ceramic Section as well as a study of their utilization as fireclay refractories. The work of the Organic Chemistry, Pharmaceutical and Drugs Section included studies of potential synthetic analgesics, including quinazoline derivatives and a new synthesis of pethidine, studies on Indian turpentine and alkaloids and attempts to synthesize compounds with sex hormone activity. In the Biochemistry Section, fermentation studies included the production of citric acid from sugar-cane molasses and of itaconic acid from glucose, using *Aspergillus terreus*; non-fermentation studies included the production of lævulinic acid from sugar-cane bagasse.

---

* Central Laboratories for Scientific and Industrial Research, Hyderabad. Annual Report, 1952. Pp. xi+57. (Hyderabad-Deccan: Osmania University Press, 1954.)

X-ray studies were made on Hyderabad clays and on stilbene derivatives, and the conductivity of lithium nitrate in mixtures of methyl and ethyl alcohol and the isomerization of chromic chloride hexahydrate were studied in the Physical Chemistry Section. The Analytical Section is working out a method for the determination of tartaric acid with potassium dichromate, and a systematic study of the fusel oil from the Nizam sugar factory, Bodham, Hyderabad State, indicated that it contains 50 per cent of amyl alcohol with fair proportions of propyl and *iso*propyl alcohol. Besides erecting the low-temperature carbonization plant, the Chemical Engineering Section determined the solubilities of groundnut oil in 98 per cent ethyl alcohol at 40–60° C., while the Operational Research Unit was concerned with the manufacture of fructose on a semi-commercial scale, of triricinolein and of sesamin.

OXFORD SYSTEM OF DECIMAL CLASSIFICATION FOR FORESTRY

FOREST bibliography has for long been a difficult subject to deal with, more especially since forestry research institutes and new forest departments and their resulting publications began to make their appearance. Certainly nowadays it would be almost impossible to keep *au fait* with the great output of forestry literature without some form of international classification.

The International Association of Forest Research Institutes—since 1929 called the International Union of Forest Research Organizations—had put the question of forest bibliography on its programme as early as 1903 with the object of creating a minimal system of classification and an international forest bibliography, the work being then entrusted to a Bibliographical Committee. The subject was discussed at the three international forestry congresses held in Rome (1926), Budapest and Helsinki. From the outset, the Swiss forester, Dr. Philipp Flury, was one of the most ardent workers in this new cause in preparation, and it was not until 1933 that the Committee presented to the International Union a complete system of classification of forest literature which was adopted in congress. It bore the title "Forest Bibliography", but became widely known as the "Flury System". It was assigned the decimal signature 634·9 F, to distinguish it from the heading 634·9 forestry in the Universal Decimal Classification, which differs in the details of its sub-division. One of the Flury System's main uses was to classify the title references comprising the International Forest Bibliography—a scheme organized by the International Union for the regular exchange between member countries of references to literature considered to be of international importance.

The first post-war meeting of the Bibliographical Committee was held in Zurich in 1948 under the chairmanship of Prof. H. Burger. At this meeting Mr. F. C. Ford Robertson, director of the Commonwealth Forestry Bureau at Oxford, presented a completely revised system of classification for forest literature which had been prepared by his Bureau in consultation with the chief research station (Alice Holt) of the British Forestry Commission and the Forest Products Research Laboratory at Princes Risborough. This revision was based upon ten years of experience gained by the Bureau in the course of its day-to-day work in abstracting and classifying the world flow of forestry literature.

When a working agreement had been reached between the International Union of Forest Research Organizations and the United Nations Food and Agriculture Organization, the International Council of the former proposed to the latter the appointment of a joint Bibliographical Committee to study the new classification and to make appropriate recommendations to both. This was to supersede the previous Committee, and on it was appointed A. Oudin, director of the Nancy Forestry School, F. C. Ford Robertson and E. Saari, professor of economics in the University of Helsinki. J. D. B. Harrison and R. G. Fontaine were appointed by the Food and Agriculture Organization. Meetings of the Committee were held at Helsinki, Oxford, The Hague, Wageningen, Oxford and Rome. During this period the new classification system submitted by the Commonwealth Forestry Bureau at Oxford was carefully examined, and at various stages of revision was widely circulated to members of the International Union and research stations throughout the forestry world. Throughout the four years of revision, the Commonwealth Forestry Bureau acted as the natural clearing house for the work of correspondence and collation involved, in which Mr. P. G. Beak, assistant director of the Bureau, proved an invaluable helper.

The definitive English text of the new system of classification (which runs to 115 pages) is called the "Oxford System of Decimal Classification for Forestry"[*] and was finally presented to the International Congress in Rome in September 1953, when it was unanimously adopted with the recommendation that translations of the English text should be published in French, German and Spanish. The Food and Agriculture Organization, at its seventh session in Rome, approved of the system with a few resolutions on the subject of periodical revisions and so forth.

SUBMARINE ILLUMINATION AND THE TWILIGHT MOVEMENTS OF A SONIC SCATTERING LAYER

By ELIZABETH M. KAMPA and BRIAN P. BODEN

Scripps Institution of Oceanography, La Jolla, California

IT has long been recognized that many zooplankton organisms exist in distinct strata during the day and that they may undergo extensive diurnal vertical migrations. The similarity of their behaviour to that of certain sonic-scattering layers in the sea, observable with echo-sounding equipment, led Johnson[1] to suggest that the origin of these layers is biological. Collections by various methods have shown that concentrations of both zooplankton and fishes are associated with these layers. Although much thought has been devoted to the composition of the layers and to the acoustic properties of the animals probably comprising them, attention to the causes of

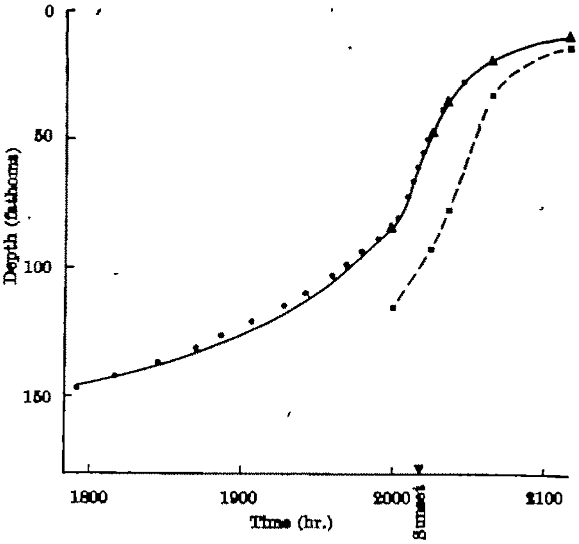

Fig. 1. Evening ascent of a scattering layer and of the 6·6 × 10^{-4} foot-candle isolume. Solid line represents top of layer as seen on *NMC*-1 fathometer record, round dots represent measured positions of the isolume, triangles represent scattering at 9·6–20 kc./s.; solid squares (– – – –) represent scattering at 2·4–3·4 kc./s.

their vertical migrations has been restricted to speculation and to laboratory experiments with individuals.

As a first step in determining these causes, the change of depth of a certain level of submarine illumination during twilight is compared here with the depths of a certain scattering layer during its vertical migration.

Intensity of illumination at depth was measured with a submarine photometer designed expressly for this purpose by James M. Snodgrass, of the Special Developments Division at the Scripps Institution of Oceanography. This instrument, described previously by Kampa and Boden[3], employs an *RCA 931A* photomultiplier tube which is sensitive to wavelengths between 300 and 700 mμ. The sensitivity has a sharp peak at 400 mμ and drops to 50 per cent at 320 mμ and 518 mμ. The tube is protected against pressure at depth by an oil-filled glass riding-light cover which makes water-tight contact with the brass cylinder containing the submerged portion of the photometer circuit.

The photometer was calibrated with a Weston illumination meter using a 100-watt *G.E.* projection bulb at 115 volts.

During the observations reported here, the submerged unit was rigged in such a way that the sensitive surface of the photomultiplier tube was vertical, favouring measurement of horizontal illumination.

When a curve of equal illumination was to be determined for comparison with scattering layer position during vertical migration, the submerged unit was lowered to the depth of the top of the layer, and the light intensity and time were recorded. This time was noted on the fathogram as well. The photometer was then either raised (sunset) or lowered (sunrise) 10 m. and held at the new position until meter readings showed that the illumination intensity was the same as that previously observed. The time was again recorded. This process was repeated until the fathogram showed that the scattering layer position had become relatively constant, either at the surface or at depth.

Scattering layers were observed with an *NMC*-1 fathometer operating at 17·5 kc./s. A more detailed analysis of the scattering properties of these layers was effected by a multiple-frequency technique similar to that employed by Hersey, Johnson and Davis[3]. The wide-band sound source in this analysis was a half-pound block of TNT detonated at the surface about 30 m. from the receiver. The receiver was a directional Rochelle salt hydrophone directed vertically downward just below the surface at the side of the ship. Sounds received by hydrophone were recorded with a 'Magnecord' 63*AH* tape-winder with *PT7-P* 'Magnecord' amplifier adapted to operate at 30 in. per sec. The record of echoes from each explosion was filtered through an H. H. Scott Type 420-*A* sound analyser, and an oscillographic record was made of the reverberation at various frequencies using a triggered single-sweep oscillograph fitted with a 'Polaroid' Land camera.

Biological collections were made from each layer under observation with a 1-m. plankton net of 8 xxx bolting silk. This net could be opened and closed at depth by means of the Leavitt[4] opening and closing device. A time–depth recorder was incorporated in the collecting gear to give a record of the fishing depth of the net. After superficial examination these collections were dark-adapted in running sea water and then deep-frozen. A report of the light-sensitive substances obtained from these animals will be presented shortly.

Fig. 1 shows the twilight ascent of a scattering layer in the San Diego Trough on June 30, as well as the ascent of the level of illumination (6·6 × 10^{-4} foot-candles) with which this scattering layer had been associated during the afternoon. It can be seen that the ascending scattering lags behind the ascending light intensity between 1830 and 1950 hours (P.D.T.).

This layer was observed to split into two components during its migration. A similar splitting of the single layer during ascent was observed on the following evening when the multiple-frequency technique was employed (risk of damage to the light meter precluded its use while TNT was being detonated). Fig. 1 also shows the ascent of this split layer on July 1. The upper component of the split layer scattered relatively high frequencies (9·6–20 kc./s.), whereas the lower component scattered only lower frequencies (2·4–3·4 kc./s.). Fig. 2 shows oscillo-

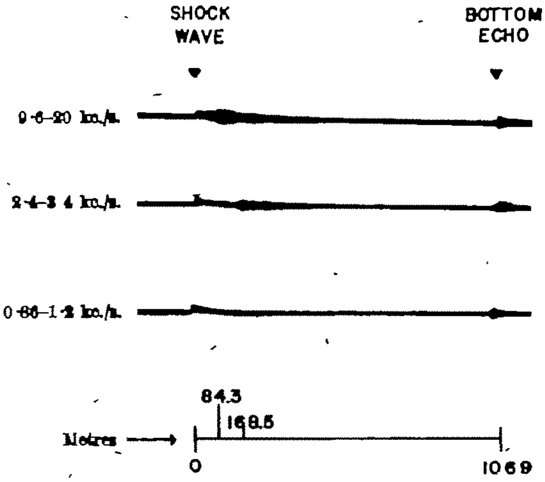

Fig. 2. Oscillogram showing back reverberation at selected frequency pass-bands. Peaks of scattering can be seen at 84·3 and 168·5 m

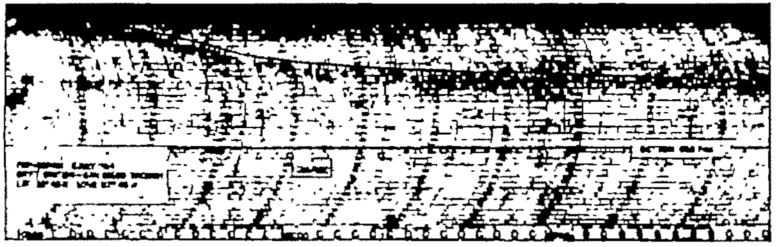

Fig. 3. Fathogram of layer descending in the morning. The $5 \cdot 9 \times 10^{-5}$ foot-candle isolume is superimposed

grams of reverberations from the second TNT explosion in the July 1 (Fig. 1) series. The upper component, scattering at higher frequencies, is apparent at 84·3 m. (46·1 fathoms), while the lower component is at 168·5 m. (92·4 fathoms).

Fig. 3 is a fathogram made in the San Diego Trough on July 2 during morning twilight to sunrise. As soon as a scattering layer could be observed breaking away from surface scattering, the photometer was lowered to the top of the layer. The intensity of illumination here was $5 \cdot 9 \times 10^{-5}$ foot-candles. The descent of the $5 \cdot 9 \times 10^{-5}$ foot-candle isolume is superimposed on the fathogram. It can be seen that the descending layer and the isolume enter and continue through a layer which had persisted through the night at about 135 fathoms.

The extremely close correlation between the vertical movements of a scattering layer and those of a constant level of illumination (Figs. 1 and 3) argues strongly that the migrations of these layers are simple responses to variations in environmental light intensity. The slight lag in the ascent of the layer behind that of the isolume (Fig. 1) during the early part of the migration suggests that, although 0·00066 foot-candles may constitute an optimum illumination for the scatterers, the threshold intensity for migration is slightly lower. This threshold was reached apparently at about 1900 hours, and the scatterers increased their rate of ascent. Shortly before sunset the layer overtook the isolume, and, at sunset when the ascent is most rapid (about 2·75 fathoms per minute), the rates of ascent of illumination-level and scattering layer are identical.

It is interesting to note that the illumination intensity ($5 \cdot 9 \times 10^{-5}$ foot-candles) with which the descending layer (Fig. 3) was associated on July 2 is less than one-tenth of that determined for the ascending layer on June 30 ($6 \cdot 6 \times 10^{-4}$ foot-candles). Assuming that these layers were similar in biological composition—an assumption which was borne out by collections taken from them—it seems that during the moonless night the animals became dark-adapted and consequently more sensitive to lower light intensities. The extent to which various degrees of dark- and light-adaptation influence the position of the scatterers relative to illumination-level demands further investigation.

Frequency analysis, at the time the fathometer has revealed the splitting of a layer during ascent, shows that the upper component, which seems to be responding to a photic stimulus, scatters sound at 9·6–20 kc./s., whereas the scattering peak of the lower component is at 2·4–3·4 kc./s. This is evidence that the upper part of the layer may be comprised of smaller organisms (invertebrates ?) and the lower part of larger ones (fish ?).

Thus we have the picture of a heterogeneous layer existing during the day at an illumination intensity which is optimum for one or more animals associated with the layer. During the evening twilight this organism ascends with its optimum intensity and is followed by predators which have been in the layer during the day. This contention is supported by the results of Tucker[5], whose analysis of net hauls taken in the layer led him to conclude that invertebrates (euphausiid crustaceans) were the dominant organisms in the upper part of the layer, while fish were dominant in the lower part of the same layer. Rigidly controlled biological collections from different components of the layer during vertical migration promise to do much in elucidating which organisms are responding to light and which are merely following a migrating food source.

This work is being conducted under contract between the Geophysics Branch of the Office of Naval Research and the Scripps Institution of Oceanography, University of California. [Aug. 7.

THE INTERTIDAL FLORA AND FAUNA OF THE CHATHAM ISLANDS

By G. A. KNOX

Zoology Department, Canterbury University College,
Christchurch, New Zealand

IN January–February 1954 an oceanographic expedition from Canterbury University College and Canterbury Museum, sponsored by the New Zealand Oceanographic Committee, visited the Chatham Islands in the M.V. *Alert*. This group of islands and rocks lies 560 miles due east of Banks Peninsula on the South Island, New Zealand, the largest member of the group, Chatham Island, being about thirty miles long. During the time spent round the Islands opportunity was taken to make observations on, and fairly complete collections of, intertidal plants and animals, at several localities on the main island and on many of the outlying islands.

The Chatham Islands lie in a zone of mixed cool sub-antarctic and warm sub-tropical water. Cool sub-antarctic water passes up the east coast of the South Island and is deflected east towards the Chatham Islands when it impinges on a tongue of warm sub-tropical water from the north, described by Fleming[1] as the East Cape Current. The area of intermingling, known as the Sub-tropical Convergence[2], is clearly defined at times, ill-defined at others, and varies considerably in position seasonally and from year to year[3]. The Chatham Islands, then, are subject to both sub-tropical and sub-antarctic influences in varying degrees, and this has an important bearing on the flora and fauna of the intertidal region.

A striking feature of the intertidal ecology of the Chatham Islands to one familiar with the New Zealand shores is the odd mixture of species characteristic of the northern and southern parts of New Zealand; for example, algae such as *Apophloea lyalii* Hook. f. et Harv. and *Pachymenia lusoria* (Hook. f. et Harv.) J. Ag., found only in the southern part of the South Island and Stewart Island, grow alongside other species, such as *Carpophyllum plumosum* (A. Rich.) J. Ag., which are limited to the northern part of the North Island. Moore[4] states that, of the 190 species of algae recorded from the Chatham Islands, ten are not otherwise recorded from New Zealand and the rest are a mixture of northern and southern species. Powell[5] has recorded 256 species of intertidal and shallow water molluscs from the Chatham Islands. Of these, forty-seven are endemic species or subspecies, and he states that there is an approximate equality in numbers of species that definitely show either northern or southern origin.

Many characteristics of the intertidal zonation, such as the absence of serpulid and *Mytilus planulatus* zones and the presence of a well-marked *Apophloea lyalii* zone, are those found only in the extreme south of the South Island and Stewart Island. Others, such as the development of *Chamaesipho brunnea* and Vermetid zones, are characteristic of the zonation of northern New Zealand shores. The basic pattern of zonation, with a well-developed *Durvillea* zone, is that of the southern, cold-temperate, New Zealand shores with some northern, warm-temperate, New Zealand features superimposed, as well as a number of endemic features.

Another striking feature is the complete absence of many of the commoner species of the New Zealand shores. Notable examples are the barnacles, *Chamaesipho columna* Spengler, *Elminius modestus* Darwin and *Pollicipes spinuosus* Quoy and Gaimard, the common intertidal serpulid, *Pomatoceros coeruleus* (Schmarda), and the molluscs, *Amaurochiton glaucus* (Gray), *Mytilus canaliculus* Martyn, *Modiolus neozelanicus* (Iredale), *Nerita melanotragus* (Smith), *Lunella smargada* (Martyn), *Scutus breviculus* (Blainville) and *Benhamina obliquata* (Sowerby). Other species, such as *Mytilus planulatus* Lamarck, were present only in very limited numbers and were not band-forming species as on the New Zealand coasts. Only one species of limpet, the endemic *Cellana chathamensis* (Pilsbry), occurs intertidally, whereas at least two or three species of *Cellana*, as well as several patelloid limpets, are to be found in most parts of New Zealand. Graspoid crabs were absent, as well as the anomuran, *Petrolithes elongatus* Milne-Edwards. On the New Zealand shores the latter species is one of the commonest and most ubiquitous animals. The complete absence of crabs above mean low-water neaps is an unusual feature not found on other southern temperate shores. Absences were not so marked among the algae, the majority of the dominant intertidal species of the New Zealand coasts being present. One example is *Durvillea willana* Lindauer, although *Durvillea antarctica* (Champ.) Hariot is abundant and another species *Durvillea caespestipes* (Mont.) Skotts[6] occupies a similar place on some Chatham shores to that of *D. willana* on the New Zealand shores.

The absence of certain species has led to some interesting changes in the vertical zonation of others when compared with their zonation on the New Zealand shores, and serves to illustrate the effect of competition in determining the limits of intertidal plants and animals. Extremely interesting and difficult to account for is the absence of the commonest New Zealand intertidal barnacle, *Chamaesipho columna*, as this species occurs throughout New Zealand, the Kermadec Islands and temperate Australia. On the New Zealand shores *Chamaesipho brunnea* occupies a comparatively narrow zone from about mean high-water neaps to mean high-water springs, above the optimum development of *C. columna* which extends down to about mean low-water neaps. On the Chathams, with the absence of *C. columna*, *C. brunnea* extends throughout the midlittoral zone down to the upper limit of the brown algal zone at mean low-water neaps. Apart from competition between adult barnacles, the difference in the breeding season of the two species of *Chamaesipho* is probably an important factor in determining their relative ranges in New Zealand. *C. columna* breeds throughout the year, whereas *C. brunnea* has a more restricted breeding season from September to February[7].

A consideration of the above evidence leads to the conclusion that the Chatham Islands intertidal region has been populated from New Zealand. This conclusion is supported by geological evidence. Finlay[8] states that the whole of the recent molluscan fauna of the Chathams seems to be independent of the Tertiary faunas, the most characteristic shells inhabiting the shores not being represented in Pliocene beds[9]. He concluded that "the Recent Molluscan fauna of the Chatham Islands is not a remnant or an evolution of the Tertiary fauna found there, but a repopulation from the mainland, in Post-Pliocene times, but yet long enough ago for characteristic regional species and sub-species to have evolved". Few endemic intertidal species have been recorded in the other animal groups and in the algae. More may, however, be recorded when the results of the present expedition have been worked out; but, apart from molluscs, nearly all the dominant intertidal plants and animals are also found on the New Zealand shores.

The absences pose some interesting problems concerning the means of dispersal of the species involved. Establishment of an intertidal population across a sea barrier can take place by the transport of sufficient numbers of larval stages by current systems, or adults by floating objects or by shipping. Drifting kelp was observed throughout the voyage to and from the islands, and it probably formed an important method of dispersal in the past. Some mainland animal species which are closely associated with brown algae, such as the anemone *Oricophorus nutrix* (Stuckey) which is practically confined to species of *Cystophora*, are also found at the Chathams; others are absent. Although *Durvillea antarctica* is abundant at the Chatham Islands, the chiton *Frembleya egregaria* H. Adams, one of the dominant species confined to *Durvillea* holdfasts on the New Zealand shores, has not been recorded. Another dominant species, *Siphonaria australis*, is rare, and was first recorded by the expedition. A second chiton, *Ornithochiton neglectus* Rocheburne, occurs abundantly in holdfasts both in New Zealand and the Chathams. Shipping may have formed a transporting agent in recent times, but it is interesting that no specimens of the barnacle, *Elminius modestus*, were found, although it has recently been introduced to Europe[10].

Crisp and Southward[11] have recently discussed the influence of sea barriers on the distribution and evolution of predominantly intertidal plants and animals and conclude that "a critical distance must exist, related to the current system and the duration of the free swimming stages, beyond which the rate of settlement of the larvæ is normally insufficient to reach the minimal population density within the lifetime of an individual". As yet there is very little information available regarding the life-histories of New Zealand intertidal animals. Information is, however, available concerning the current velocities between New Zealand and the Chathams. Young[12] reports that light wreckage from Cook Strait has been picked up three weeks later on the north side of Chatham Island. Drift bottles liberated off the Otago Heads have been picked up on various parts of the island from 3 to 15 months later[13]. The velocities of these currents would be sufficient to transport the free-swimming larvæ of many species.

Detailed results of this investigation of the intertidal ecology of the Chatham Islands will be published elsewhere. The expedition which enabled the above observations to be made was financed by a grant from the New Zealand Council of Scientific and Industrial Research, with contributions from Canterbury University College, Canterbury Museum, the Dominion Museum and the Canterbury Branch of the Royal Society of New Zealand. This assistance is gratefully acknowledged. I also wish to thank Dr. M. Naylor and Mr. R. K. Dell for helpful discussion.

EXPERIMENTAL CHEMICAL CARCINOGENESIS AND THE INFLUENCE OF SOLVENTS

RESEARCH IN FINLAND

By Prof. KAI SETÄLÄ

Department of Pathology, University of Helsinki

STUDYING the mechanism of experimental tumorigenesis there are—besides the cancer-provoking agent itself—several factors influencing essentially the development of tumours. The majority of these factors are, however, still totally unknown. Even the few which can be regarded as known need further explanation. It may therefore be of value to summarize some of our present knowledge and try to illustrate the significance of some of the observations already obtained.

Cancer-provoking agents as used in experimental research are, in general, the fat-soluble aromatic polycyclic hydrocarbon carcinogens. When they are employed for an investigation on living biological material, it is necessary to bring these fat-soluble substances into close contact with the aqueous environment of the organism. In applying fats and/or fat-solvents as vehicles for the carcinogen, a number of factors, not easily controllable, are introduced which modify the results. A considerable number of investigations dealing with factors which alter the action of tumorigenic agents confirm the existence of some kind of 'solvent effect'. The nature of this is unknown. That is why the effect of the vehicle used and that of the actual carcinogenic agent cannot be clearly distinguished from each other. It seems possible, however, that a satisfactory explanation of this particular circumstance would throw additional light to the question how the carcinogenic hydrocarbons actually function.

Selecting suitable mediators for the carcinogen, it is logical to examine the physiology and pathology of living matter for suggestions as to their required nature[1–3]. One should take into account the large body of data which has been accumulated, for example, upon the chemistry and fine structure of protoplasm and its derivatives, intercellular substances and the permeability phenomena. (On these matters I consulted (at the beginning of 1946) Prof. R. Collander (Institute for Botany, University of Helsinki), a leading investigator on the permeability of cells, who agreed with this view, and made some illuminating comments.) The vehicles in the present experimental series ought to satisfy, so far as possible, the following demands: (1) in principle they should be as 'physiological' as possible; (2) they must be well known and chemically well defined; (3) they must have the property of solubilizing both water- and fat-soluble substances; and (4) it must be possible to vary the chemical and the physical nature of the resulting solutions within wide limits when needed. It seems, therefore, natural that the vehicles should be nonpolar–polar compounds having their principal counterparts in living Nature[1–10]. For experimental studies, compounds of varying nonpolar–polar behaviour can be selected, either from the biologically active, natural nonpolar–polar substances or from the technical products known as detergents (cf. refs. 4, 5, 8 and 10). (From the beginning of 1947 until 1951, Prof. P. Ekwall (Institute for Physical Chemistry, Åbo Akademi, Turku, Finland) acted as chemical adviser in our studies in the field of aqueous solutions of association colloids[7].) Since 1946 I have systematically employed certain synthetic high polymers—for example, solutions of various polyethylene glycols (carbowaxes). It appeared that both these compounds and the so-called 'association colloids' which were brought into use later during our studies[7] have some common properties from the physico-chemical point of view[5,6,7].

Before investigations concerning the actual mechanism of experimental carcinogenesis could be started, some orientating tests were made (regarding the maintenance of the carcinogenic activity, differences in carcinogenic response of tissues when various types of nonpolar–polar vehicles are employed, the significance of the carcinogen and the colloid concentration, penetration and absorption of the carcinogen into various tissues, the possible transport mechanism, etc.). Some of the aspects are dealt with in the following. (Investigations have been carried out since 1945.)

Tumorigenic power. The first task was to test if the carcinogenic hydrocarbons solubilized by these nonpolar–polar mediators retain their tumorigenic activity. The tumorigenic power was tested using various strains of mice. In systematic studies, however, mice of our anonymous known strain employed in all our experiments were used. Up to the present, about 15,000 animals have been expended. For the orientating experiments, only relatively small series (ten to twenty mice in each subgroup) were at our disposal. The reasons for this were two-fold: the wide scope of the programme, and post-war difficulties in Finland. In the actual experiments, larger series (fifty to two hundred mice in each subgroup) were employed (see refs. 9, 13).

A priori, it was far from certain that these nonpolar–polar mediators would retain their activity (cf. ref. 11, pp. 56–59). So far, a great number of different representatives of nonpolar–polar mediators (both ionic and non-ionic ones) has been studied. It has now been established with certainty that carcinogens retain their carcinogenity and induce cutaneous[1–3,5,8,12], fore-stomach[3,6,13] and subcutaneous[3,9] tumours. In addition, there are significant differences in the average response when different vehicles are employed. Further, tumours can be induced by applying only a fraction of the quantities of the carcinogen reported in the literature.

Cutaneous tumours developed with a concentration, for example, of 0·0045 per cent of 9,10-dimethyl-1,2-benzanthracene in aqueous solutions of sodium lauryl sulphate[3,6,9]. The average time of response decreased with increasing concentration of the nonpolar–polar compound, and the fact that this time decreased at first faster with higher dilutions, and then more slowly, seems to indicate that the physico-chemical nature of the vehicle is important. The concentration of the nonpolar–polar substance is significant when the carcinogen concentration is low. At higher carcinogen concentrations, already at 0·009 per cent dimethyl-benzanthracene, the colloid concentration seems to be of secondary importance. These observations may perhaps be interpreted as indicating that the concentration, for example, of 0·03 per cent dimethyl-benzanthracene (a usual concentration in experimental work) is, in general, high enough to avert variations depending on differences in the physico-chemical nature of nonpolar–polar vehicles. Furthermore, these observations indicate that one has to use relatively low carcinogen concentrations when the significance of well-defined vehicles is studied[8].

Fore-stomach tumours developed in feeding experiments with a total dose of 0·6–4·0 mgm. dimethylbenzanthracene per mouse when various types of aqueous solutions of detergents acted as mediator, and on an average of 1·6 mgm. when polyethylene glycols were used[3,6,13].

Penetration and absorption of the carcinogen. As to the skin, fluorescence studies indicated, first, that 3,4-benzpyrene, as well as other carcinogens, solubilized by aqueous solutions of various nonpolar–polar compounds, easily penetrate into the cutaneous elements[1–3,6,8,12], and secondly, that the localization and distribution of benzpyrene or its blue fluorescent metabolites, shortly after painting on the skin, depend on what types of nonpolar–polar substances are used[8]. The characteristics of the mediator substance seem to affect the rate at which the carcinogen is absorbed by the skin and the pathways for the passage of the carcinogen through the skin[5,8,9]. In addition, it appeared that benzpyrene can penetrate directly into the living epidermis and dermis in newborn mice when the carcinogen is applied before the tenth hour of life, that is, before the development of the pilo-sebaceous apparatus[3,14].

As to the gastrointestinal tract, gastric absorption of 3,4-benzpyrene was studied following gastric instillation of a single dose of the hydrocarbon. No signs of absorption or penetration by benzpyrene of the gastric glandular mucosa were observed after administration of the hydrocarbon in fat and oils. This is understandable, because little or no fat is absorbed by the glandular stomach wall under normal conditions. On the contrary, for penetration into this region the physico-chemical nature of the mediator substance is decisive. With substances possessing nonpolar–polar properties a weak penetration is observed if the lipophilic characteristics predominate, and a strong penetration if the hydrophilic characteristics are predominant. This was first observed using water-soluble polyethylene glycols[15]. Later it appeared that both these compounds and aqueous solutions of the actual association colloids (namely, soaps and soap-like substances) cause penetration into the gastric glandular mucosa[3,6,13,16]. Aqueous solutions of certain natural biological nonpolar–polar substances, such, for example, as those of bile acid salts and of higher fatty-acid salts, also cause penetration of benzpyrene into the glandular mucosa of the stomach[3,6,16].

Observations on the transport mechanism of the carcinogen. The mechanism determining the distribution in the body of carcinogenic hydrocarbons is a complicated phenomenon. However, certain facts suggest it being likely that the absorption (cf. also the preceding) and the transport mechanism of these substances are in some way linked to those of lipids. However, comparatively little is known about the physical state in which the carcinogen—shortly after its administration to the experimental animal—travels in the aqueous fluids of the body. After having examined the influence of some agencies (histamine administration, X-ray radiation of certain regions of the body) upon the behaviour of the so-called chylomicrons, that is, mobile visible lipids of the blood (cf. ref. 17), it was observed, first, that large amounts of benzpyrene or its blue-fluorescent metabolites exist in the content of the mesenteric lymphatics and in that of the thoracic duct after gastric instillation of the carcinogen[3,6], and secondly, that benzpyrene moves in the blood stream, at least to some extent, in association with chylomicrons[18]. It was also possible indirectly to confirm this by preparing 'artificial chylomicrons' containing various nonpolar–polar substances, globulins and 3,4-benzpyrene. If the resulting solutions contain certain biological nonpolar–polar compounds in varying suitable proportions, the size and the behaviour of these particles can be changed within wide limits when needed[9]. Further, parenterally administered fat, if emulsified with nonpolar–polar substances, enters the blood stream in the form of small visible particles, so-called lipomicrons, the physical state of which most probably is similar to that of the alimentary chylomicrons[19]. This happens also when large amounts of these nonpolar–polar compounds are painted to the skin of mice[9]. It is possible that the observations presented here may throw additional light on the problem how experimental remote tumours 'sediment' themselves.

Morphological changes induced by nonpolar–polar compounds. Ever since the recognition of skin carcinogenesis, attention has been paid to various changes in cutaneous elements as well as to the interaction between such changes caused by carcinogenic tars and hydrocarbons (see review in ref. 11, pp. 159–163). Already during the orientating experiments of the present series with water-soluble polyethylene glycols[1,2,4], and later also in connexion with aqueous solutions of other detergents[5,6,9], it appeared that some of the mediators induced different types of epilation phenomena from those usually observed in skin carcinogenesis. In the present phase of the studies, it is certain that some of the nonpolar–polar compounds, without any known carcinogen, can cause morphological alterations in various cutaneous structures. For example, painting of the skin with the non-ionic polyoxyethylene sorbitan mono-oleate ('Tween 80') with a high hydrophile–lipophile balance value (cf. ref. 8) caused distinct alterations, especially in the subcutaneous adipose tissue[20]. On the other hand, another non-ionic detergent, sorbitan monolaurate ('Span 20'), with much lower hydrophile–lipophile balance value induced alterations both in the epidermis and dermis: enlargement of the individual cells, increased mitotic ratio, distinct thickening of the epidermis, destruction of the pilo-sebaceous apparatus, changes both in the intercellular matrix and in the connective tissue proper, dilatation of capillaries, degenerative changes in the vascular walls, etc.[9,12].

Using systematically selected nonpolar–polar compounds (for example, synthetic detergents) and high polymers (for example, polyethylene glycols), without any known carcinogen, it is possible to induce (within wide limits) various types of morphological changes in epidermis, dermis, or in both (as well as in some remote organs), in experimental animals, some of which are seen in connexion with carcinogenesis. Taking into account, first, the principles according to which certain of these compounds have been selected (for example, what is known about interactions between synthetic detergents as well as high polymers and various proteins[10]), and, secondly, what is known about connective tissue physiology and pathology, it is possible to throw additional light to the mechanism and pathogenesis of some of these alterations. Here we have at hand a better method for distinguishing the influence of a well-defined carcinogen from that of a well-defined vehicle.

Mechanism of experimental skin carcinogenesis. After these orientating studies, some observations upon the pathogenesis of experimental skin carcinogenesis may be considered. It has been reported that new-born mice (2–10 hr. after birth) are refractory to a single application of the carcinogen. The absence of pilo-sebaceous apparatus and also the thicker epidermis of new-born mice would explain the ineffectiveness of the carcinogen for penetration and tumour formation. In our studies the co-carcinogenic action of croton oil (cf. ref. 11, pp. 151–164) on the skin of new-born mice painted once with 9,10-dimethyl-1,2-benzanthracene during the first 10 hr. of their life was tested[9]. As a result cutaneous tumours do not develop, though the carcinogen easily penetrates into the cutaneous elements (*loc. cit.*). The reason for this seemingly negative result must thus be found elsewhere[9]. Following this work, series of adult mice received a single painting of 9,10-dimethyl-1,2-benzanthracene solubilized by various nonpolar–polar compounds. After this, croton oil treatment was carried out in the usual manner. The co-carcinogenic effect of this mixture became apparent as expected beforehand[9]. Taking into account the nature and morphology of the alterations in the skin induced by certain nonpolar–polar compounds, in another series of adult mice some of these compounds (for example, 'Span 20') were employed as co-carcinogens. As a result, cutaneous tumours developed at the site of painting[9,13]. These compounds are favourable for this kind of experiment because they do not induce cutaneous tumours when used without any known carcinogen. In other words, a considerable number of well-defined and biologically active colloid-forming compounds (both ionic and non-ionic) can serve as co-carcinogens as effectively as croton oil. (It is of interest that croton oil also contains several nonpolar–polar compounds which are able to react, for example, with proteins.) A large series of other well-defined co-carcinogenic agents is already under test. The results available so far point in the same positive direction[9]. To sum up, a new group of chemically and physico-chemically well-defined co-carcinogenic compounds has been discovered.

Accordingly, it would seem that the existence of a 'solvent effect' has become apparent in several different ways. We are continuing investigations on the following lines: (1) to search for powerful co-carcinogens from the large series of well-defined and well-known natural and synthetic nonpolar–polar compounds, high polymers, etc., having certain effects upon different biological systems; (2) to study the specific mode of action upon living matter of each of the principal different types of these agents. Employing series of systematically selected well-defined co-carcinogenic compounds with known influences upon various tissue elements, something of the tumorigenic property of the 'actual' carcinogen can gradually be transferred to these co-carcinogens. In this way it may be possible to investigate, among other matters, what is meant by the present concepts 'carcinogenic' and 'co-carcinogenic', what types of morphological and chemical (analysed, for example, with X-ray diffraction and biochemical methods) alterations in the elements of origin for tumour formation are essential, as well as interactions between parenchymal and stromal reactions during tumorigenesis—that is, the power to induce tumours under controlled conditions—and thus to throw more light on the biological processes, as a result of which experimental tumours develop.

Some of these investigations have been aided by grants from the Sigrid Juselius Foundation of Helsinki. [June 30.

Effects of Ribonuclease on the Metabolism of Living Root-Tip Cells

USING ribonuclease as an analytical tool, Gale and Folkes[1] have recently brought forward new evidence for the hypothesis that ribonucleic acid plays an important part in protein synthesis[2,3]. A recent report, by Kaufmann and Das[4], that ribonuclease induces mitotic abnormalities in root-tip cells, shows that the enzyme actually can penetrate into living root-tips. These findings led to the present study on the effects of ribonuclease on the metabolism of nucleic acids, protein and respiration in onion root-tips. The experiments have been performed with the technical help of J. Brygier, E. Baltus and F. Vanderhaeghe.

When intact onion root-tips are treated with crystalline ribonuclease (1 mgm./ml.) for a few hours prior to immersion in water containing a labelled amino-acid (radioactive glycine or phenylalanine), there is considerable inhibition of the incorporation of amino-acid into the proteins: a 50 per cent inhibition is observed after pre-treatment for 1 hr. with ribonuclease, and it reaches almost 90 per cent after treatment for 3 hr. with the enzyme. These biochemical results have been confirmed by using an autoradiographic method: as seen in Figs. 1 and 2, treatment for 3 hr. with ribonuclease considerably reduces the uptake of labelled phenylalanine into the cells. Inactivated crystalline ribonuclease showed no effect on the incorporation of the labelled amino-acids into the proteins of the root-tips.

Very different results are obtained when the incorporation of labelled adenine in the nucleic acids is studied: treatment with ribonuclease first increases the incorporation of adenine into ribonucleic acid, the increase reaching 60 per cent for a 3-hr. period. Incorporation then steadily decreases, so that in root-tips treated for 20 hr. with ribonuclease, 80 per cent inhibition is found. As regards deoxyribonucleic acid, the incorporation of labelled adenine is immediately reduced: the inhibition reaches 30 per cent during a period of 1–3 hr. and it becomes practically complete after 20 hr. These observations suggest that ribonuclease immediately slows down deoxyribonucleic acid synthesis, leading to the cytological abnormalities described by Kaufmann and Das[4], while it first stimulates, then inhibits ribonucleic acid metabolism.

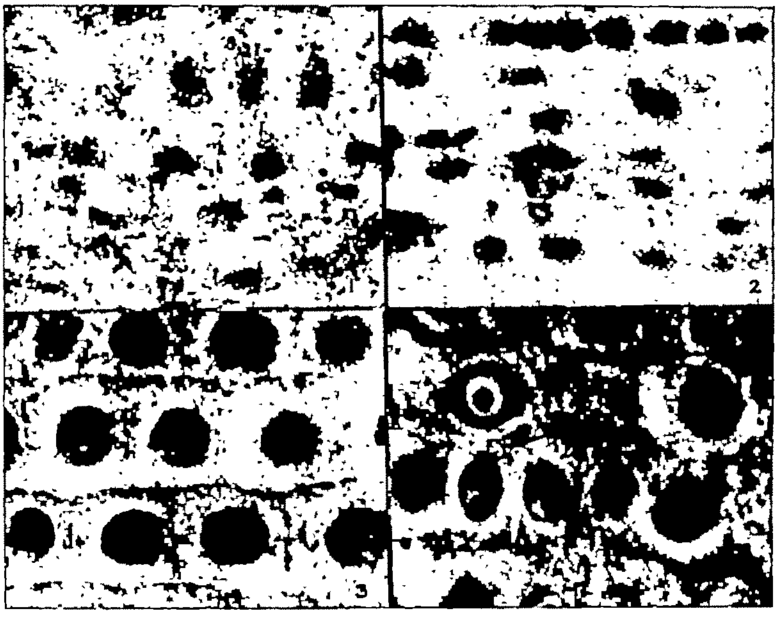
In contrast to these striking changes in protein and nucleic acid metabolisms, the oxygen consumption of the root-tip meristematic tissue remains unaffected by ribonuclease, even after treatment for 15 hr.

While the oxidative activities of the mitochondria thus apparently remain normal, phosphorylations are effected by the ribonuclease treatment: the inorganic phosphate content drops by 20 per cent during the first 3-hr. period, without any further changes. At the same time, acid-labile organic phosphate (presumably adenosine triphosphate) shows a 30 per cent increase during the first 3 hr. of the ribonuclease treatment and remains constant afterwards. These results probably mean that adenosine triphosphate is not utilized and thus accumulates, when protein and deoxyribonucleic acid metabolisms are inhibited by ribonuclease.

Ribonucleic acid, when estimated spectrophotometrically according to the method of Ogur and Rosen[5], shows a 20 per cent drop after the root-tips have been treated for 3 hr. with ribonuclease; there is no further decrease afterwards, even after 18 hr. Soluble nucleotides seem to drop slightly at the beginning (1–3 hr.), then steadily increase, finally reaching a value 40–50 per cent above controls after 18 hr. It should be pointed out, however, that classical methods of estimation of ribonucleic acid might be misleading if the nucleic acid of the cells is partly degraded by ribonuclease. It seems, nevertheless, that the strong inhibition of protein metabolism is not linked to any extensive degradation of ribonucleic acid.

This conclusion is confirmed by cytochemical observations on cells treated with ribonuclease: after Unna staining, the cells of the outer layers are more basophilic than normally after 3 hr. in ribonuclease. The increased basophilia is due to ribonucleic acid, as shown by the ribonuclease test[3]; it is thus likely that the enzyme first induces a synthesis of ribonucleic acid in the external cells. Later on, after 6 hr., for example, this outer layer of cells loses its basophilia almost completely.

An interesting point is that when sections of roots previously treated *in vivo* for 3 hr. with ribonuclease are stained with Mazia's[6] method for proteins, an empty space becomes visible around most of the nucleoli (Figs. 3 and 4). This finding might



Track-radioautograph of onion root-tip cells incubated in radioactive phenylalanine. Control (1) and after treatment by ribonuclease (2)
Sections of onion root-tip cells stained by Mazia's method. Control (3) and after treatment by ribonuclease (4)

mean that, as proposed by Caspersson[2], the nucleolus plays a very important part in protein synthesis, in agreement with the experimental data obtained in this laboratory by A. Ficq[7].

These results, in showing that ribonuclease produces a very strong inhibition of amino-acid incorporation into the proteins of living cells, bring fresh evidence for the view that ribonucleic acid is intimately concerned with protein synthesis. The accumulation of adenosine triphosphate in the treated cells as well as the fact that ribonucleic acid only partly disappears after treatment by ribonuclease agree well with Dounce's hypothesis[8] that a phosphorylated form of ribonucleic acid is involved in a template mechanism of protein synthesis. It should finally be pointed out that ribonuclease, when acting on living cells, exerts effects comparable to those of the removal of the nucleus in unicellular organisms[9]; for in such cases, ribonucleic acid decreases together with protein anabolism, while adenosine triphosphate increases and oxygen consumption remains unaffected.

Inactivation of the Chromatophore-expanding Activity of Pituitary Extracts by Ascorbic Acid

IN experiments dealing with the connexion between the adrenocorticotrophic hormone (ACTH) and intermedin, we have tried to protect the hormone from inactivating oxidation by the addition of substances with a low redox potential. Among others, ascorbic acid (Merck) has been used, as it is well known that it protects for several hours from oxidation, for example, highly diluted solutions of sympathins. But contrary to expectation, it was found that after the incubation of an adrenocorticotrophic hormone preparation of Schering in a Ringer solution containing 10 mgm./100 gm. ascorbic acid at + 4° C. overnight, its original chromatophore-expanding activity was found to be reduced to 2 per cent.

We have therefore tried in a number of experiments to get some information upon the mechanism of the reaction between ascorbic acid and the active polypeptide. Experiments were carried out on Voegtlin–Standard powder, on ACTH–Schering, and on corticotrophin-*B* 52*R*6239 (kindly supplied by N. Brink, Merck). The chromatophore-expanding activity of the extracts was estimated from the permeability to light of isolated frog skin in a Pulfrich photometer. By this method a straight dose – response curve can be obtained by plotting the logarithm of the dose against the ratio (Δ extinction of each dose)/(Δ extinction of a standard dose). The slope of this curve is about 1, λ about 0·1. Using an ACTH preparation of Messrs. Schering (1 mgm. = 3 I.U. ACTH) the threshold was 0·001 μgm. of the dry extract per ml. Ringer solution, for corticotrophin *B* (1 mgm. = 150 I.U. ACTH) between 0·0002 and 0·0005 μgm. per ml. Ringer. To compare the activities of preparations treated in different ways, the six-point assay technique has been used. The following results have been obtained.

(1) A depletion of the chromatophore-expanding activity of Voegtlin powder by 90 per cent after 0·5 μgm. (= 10 melanophore-expanding units, M.E.U.) has been incubated at room temperature in 10 ml. Ringer solution containing 10 mgm./100 gm. ascorbic acid (*p*H 6·6) for 1 hr.; under similar conditions a depletion of the chromatophore-expanding activity of ACTH–Schering (3·95 μgm. (= 900 M.E.U.) per ml. ascorbic acid Ringer) by 70 per cent after 2 hr., by 85 per cent after 4 hr., by 96 per cent after 20 hr. incubation.

The chromatophore-expanding activity of corticotrophin-*B* (5 μgm. (= 1,880 M.E.U.) per ml. ascorbic acid Ringer) shows in several experiments a mean depletion by 22 per cent after 4 hr., 52 per cent after 12 hr. and 88 per cent after 28 hr. when compared with the spontaneously declining activity of the control solutions containing no ascorbic acid. Lower concentrations of ascorbic acid, for example, 0·1 mgm./100 gm., also produced inactivation. Inactivation occurred whether atmospheric oxygen was present or not.

(2) If ACTH–Schering was incubated in a solution containing dehydroascorbic acid and *l*-gulonic acid, the depletion after 20 hr. was only 58 per cent against 99·16 per cent with ascorbic acid.

(3) If the pituitary extracts were incubated for 2 hr. in solutions containing ascorbic acid plus cystein, or thiourea, or 8-hydroxyquinoline, their activity on frog skin was reduced by approximately 40 per cent of that of the control. But this depletion did not increase, although the incubation was prolonged for another 18 hr. Cystein, thiourea and 8-hydroxyquinoline themselves did not significantly influence the chromatophore-expanding action of the pituitary extracts tested.

Details of this work will be published elsewhere.

Interrelationships between a Yeast and a Bacterium when growing together in Defined Medium

SINCE the introduction of solid medium, the isolation of micro-organisms in pure culture, formerly a matter of considerable difficulty, has become a relatively easy process. The numerous studies of micro-organisms in pure culture which resulted have enabled the science of microbiology to develop rapidly. In Nature, however, micro-organisms are rarely found in pure culture, and there is a need for investigation of the growth and metabolism of organisms growing in association with each other. Woods[1] has recently stressed the need for such research. The present study of a yeast (*Saccharomyces cerevisiae*) and of a bacterium (a *Lactobacillus* species) growing separately, and also when growing in association with each other in defined media, was commenced approximately two and a half years ago and is concerned mainly with the nutritional requirements of the micro-organisms. A number of interesting relationships between the organisms when in mixed culture have been observed.

The medium employed in these studies was nutritionally adequate for each of the two micro-organisms and contained: glucose (6 per cent), casein hydrolysate (1 per cent) and the following growth factors: inositol 10 μgm./ml., D-biotin 2·2 mμgm./ml., calcium-D-pantothenate 2 μgm./ml., thiamine 2 μgm./ml., pyridoxin hydrochloride 2 μgm./ml., nicotinic acid 2 μgm./ml. and pteroylglutamic acid 100 mμgm./ml. In pure culture, the yeast requires an exogenous source of inositol, biotin and pantothenic acid: thiamine, nicotinic acid and pyridoxin are stimulatory. The *Lactobacillus* requires biotin, pantothenic acid, nicotinic acid, thiamine and folic acid (pteroylglutamic acid).

The *Lactobacillus* failed to grow in the defined medium when either nicotinic acid or thiamine was absent. In mixed culture with the yeast, however, the lactobacilli grew moderately well in the absence of either of these growth factors, but only when the concentration of the other growth factors in the medium was considerably reduced, that is, as compared with the concentration normally present. Thus, in the absence of nicotinic acid, the growth of the lactobacilli in mixed culture was greatest when the other growth factors were present at approximately one-twentieth of the concentration normally employed. In such cultures growth of the yeast is restricted, and it would appear that the organism is synthesizing nicotinic acid, or some substance which can replace the nicotinic acid requirement of the *Lactobacillus*, and secreting it into the medium where it becomes available to the *Lactobacillus*, which is thus able to grow. It was shown that the yeast when growing alone in such media did in fact secrete such a substance in the medium; further examination of the yeast culture filtrate showed that the active substance was nicotinic acid itself or its amide. Addition of this yeast culture filtrate to medium not containing nicotinic acid and inoculated with the lactobacilli enabled the bacteria to grow, whereas no growth occurred in this medium when yeast culture filtrate was not added.

Similar interrelationships were observed in connexion with the purine requirements of the *Lactobacillus*. The yeast does not require either purines or pyrimidines for growth, whereas the *Lactobacillus* needs an exogenous supply of adenine, guanine and uracil—or hypoxanthine together with uracil. The *Lactobacillus* failed to grow in media lacking adenine or guanine or both, but did so when in mixed culture with the yeast: such growth, however, occurred only in media in which the vitamins were present at sub-optimal concentrations, that is, media in which yeast growth was restricted.

Eight interrelationships were observed in connexion with the amino-acid requirements of the *Lactobacillus*. Its requirements were determined in a glucose medium in which amino-acids were the sole source of nitrogen, and the organism was found to be exacting to ten of the acids: two other amino-acids were stimulatory. In media lacking any one of eight of these twelve amino-acids the *Lactobacillus* grew to a very limited extent or not at all, whereas in mixed culture with the yeast the bacterium was able to grow to an appreciable extent; such interactions were most marked in media lacking aspartic acid, tryptophan, glycine, alanine or lysine, and only occurred when the vitamin concentration was sub-optimal (approximately one-tenth of the concentration normally employed), that is, in media in which yeast growth was restricted. The filtrates of pure yeast cultures grown in such media were shown by chromatographic or other methods to contain the missing amino-acid or some substance which could replace it.

In all, some thirteen inter-relationships between the yeast and the *Lactobacillus* have so far been observed, and in each of them the yeast appears to be the active organism, that is, to have synthesized the missing substance essential for the growth of the *Lactobacillus*. The substances concerned are widely different in nature and include vitamins, purines and amino-acids. It is suggested that other methods of restricting growth of micro-organisms may well repay investigation, for example, alteration of *p*H or of degree of aerobiosis or of incubation temperature.

Effect of Streptomycin on the Host – Pathogen Relationship of a Fungal Phytopathogen

IN these laboratories we have found tomato and potato suitable subjects for the study of the effect of streptomycin on host – pathogen relationships and have observed an interesting effect of this anti-bacterial substance on the course of development of infections due to *Phytophthora infestans*. Bonde[1] has reported a similar effect from the absorption of terramycin hydrochloride through the cut stems of Katahdin potato plants, but failed to obtain an effect with streptomycin even at concentrations of 100 μgm./ml.

We applied the antibiotic via the root system by exposing 35-day old plants to nutrient solutions containing different concentrations of streptomycin calcium chloride for one week. The effect on the reaction of the host to infection was examined by inoculation of detached leaves with a zoospore suspension applied in filter-paper disks and incubated at 20° C. in a moist chamber. In one experiment whole plants were sprayed with a zoospore suspension.

The concentration of streptomycin in leaf tissue was determined by bio-assay, and the toxicity of the antibiotic to the pathogen was tested *in vitro*.

The main results were as follows. In both potato and tomato a marked protective effect was observed at concentrations which had no effect on the vegetative development of the plants. In the case of tomato, even 4 μgm. of streptomycin per ml. of nutrient solution completely checked the disease. However, infection itself is not prevented by the presence of streptomycin in the tissue, but spread of the parasite is restricted after contact with the host plasm in contrast to the diffuse spreading noted in the untreated plants. The parasitized host cell dies and, very often, the surrounding tissue becomes chlorotic.

The concentrations supplied and those in extracts of treated plants have been shown to have no significant effect on zoospore development or germination of the parasite. *Phytophthora* mycelium tolerated streptomycin at concentrations even of

200 μgm./ml. However, slight depression of growth was observed at 8 μgm./ml.

The suppressive effect on the growth of the pathogen in living tissue was tested further by inoculation of cut tuber surfaces treated with streptomycin solutions and rinsed to remove free antibiotic. It was found that higher concentrations were required to obtain a checking effect in this work. A slight depression of sporulation occurred at 60 μgm./ml., and complete inhibition was observed at 200 μgm./ml.

It appears that when absorbed by the host cell streptomycin is firmly held, since there is little movement to tissue developed after the plant is removed from treated to normal nutrient solutions. Thus in one series of plants, *Phytophthora* developed rapidly on axillary shoots, but there was a slight reduction of sporulation on the basal leaves indicating that some translocation may have occurred.

There is a difference in response between organs of treated plants, the effect being more marked in leaves of both potato and tomato than in tubers or fruits. There are indications that young leaves respond more definitely than older ones.

Streptomycin does not exert a general protective effect against fungal pathogens. Even when treated with a concentration of 100 μgm./ml., many potato plants were severely attacked by powdery mildew (*Erysiphe solani Vanha.*).

If one assumes that streptomycin is evenly distributed within the cell and total extraction of streptomycin is obtained, the concentrations demonstrated by bio-assay of tissue extracts cannot be responsible for the effects observed. It would appear, then, that the antibiotic is either: (*a*) unevenly distributed in such a way that the parasite contacts lethal concentrations at the surface of the cell where parasite and host plasm first establish contact; or (*b*) it induces some change which alters the host–pathogen relationship in such a way as to confer some degree of resistance to the host.

Further experimental work will be required for the elucidation of the mechanisms involved in these changes of the host–pathogen relationship.

Reaction between Phthalein Dyes and Heated Foodstuffs

A TENTATIVE method for the estimation of the quality of soybean oil meal, based on varying ability of different meals to absorb or react with phenolphthalein, has been briefly described[1]. Properly heated meals absorbed or reacted with significantly more phenolphthalein than under-heated samples, and over-heated samples somewhat more than the properly heated ones.

Since then, a variety of other dyes has been tried, but it was found that only phthaleins like phenolphthalein, phenol red, bromothymol blue, and cresol red reacted in this characteristic way. Other dyestuffs tried—methyl red, methylene blue, fuchsin—were absorbed to about the same extent regardless of the heat treatment of the meals. Further, it was found that the absorption of the phthalein dyes was rather independent of the fineness of the sample. From these facts it is concluded that there is not only an absorption but also a staining reaction between the phthalein dyes and substances in the soybean oil meal, especially those formed by heating (the Browning reaction).

From the experiments with the different phthalein dyes it has been found that phenolphthalein under given conditions best distinguishes between under-heated, properly heated and over-heated meals. It has, however, the disadvantage of not being stable when made alkaline in presence of substances present in soybean oil meal. The solution must be made alkaline immediately before the reading in the photometer. It is supposed that the substances in the alkaline medium form products which react with phenolphthalein. Cresol red is much more stable, and when using this dye the method has been simplified as follows: 400 mgm. samples are weighed in centrifuge tubes and 10 ml. freshly mixed reagent solution (one part of an alcoholic solution of cresol red, 2 mgm./ml., and nine parts of 0·1 *N* hydrochloric acid) are added. The tubes are shaken for one hour and then centrifuged. One ml. of the supernatant is added to 10 ml. 0·02 *N* sodium hydroxide. The colour is read in a spectrophotometer at 5,700 A.

Some results from the experiments with this method are given in Table 1. From this it is seen that there is a marked tendency of heated meals to absorb (react with) more cresol red as compared with under-heated samples.

Table 1. ABSORPTION OF CRESOL RED BY DIFFERENT SOYBEAN OIL MEALS

Character of the soybean oil meal*	Number of meals tested	Photometer readings (% transmission)	Mgm. cresol red absorbed per gm. meal
Much under-heated	6	9–15	2·5–3·0
Under-heated	4	21–28	3·3–3·8
Properly heated	8	30–52	4·0–4·3
Over-heated	2	54–55	4·4–4·5

* As indicated from laboratory determinations and chick growth experiments.

This cresol red test has also been performed with some samples of rape seed meal, linseed meal and dried milk. Even with these, correlation between heat treatments and cresol red absorption was found. Details of these experiments will be published elsewhere.

Induction of Tumours with 1-(2-Tolylazo)-2-naphthol (Oil Orange *TX*)

PEACOCK[1] induced hepatomas in seven of seventeen mice surviving subcutaneous injection of oil orange *E* (1-benzeneazo-2-naphthol) for more than fourteen months. This substance was then in use as a food dye. Clayson[2] has since suggested that it might be active by virtue of its *in vivo* reduction to 1-amino-2-naphthol. If this be so, it was thought that other compounds capable of being reduced to this aminonaphthol might be carcinogenic.

1-(2-Tolylazo)-2-naphthol was purified by chromatography on alumina. 3 mgm. of this compound as a 3 per cent solution in arachis oil were injected subcutaneously into albino mice twice a week for fifty weeks. Of thirteen mice which survived for more than forty-six weeks, three developed spindle-cell sarcomas at the site of injection at 46, 53 and 61 weeks respectively (Table 1). In another three mice, tumours of the intestine were found. The first of these was detected by palpation before the mouse was killed, 62 weeks after the commencement of treatment. It was an adenocarcinoma arising in the region of the ileo-cæcal junction, probably in the cæcum, invading through the muscular coat and spreading extensively in the omental lymphatic vessels. There was a secondary deposit in a para-ileal regional lymph node. On microscopical examination in another mouse killed after 69 weeks, an adenocarcinomatous polyp was seen in the cæcum close to the junction with the ileum. At the base of this tumour there was invasion of the muscular coat, and a nodule of adenocarcinoma, probably situated in a lymphatic vessel, was found in the omentum. The third tumour, which arose in a mouse treated for 65 weeks, was detected macroscopically as a thickening of the small intestine. It proved to be an adenomatous polyp of such irregular structure that early malignant change was suspected, but neither invasion of muscle nor metastasis was found.

Table 1

Experimental mice				Control mice	
Weeks of survival after beginning treatment	Local sarcoma	Intestinal tumour	Other findings	Weeks of survival after beginning treatment	Findings
46	+			46	
				46	
53	+		Lung adenoma		
54				59	
61	+		Lymphoma		
62				64	Lymphoma
62		+		64	Lymphoma
65		+	Lymphoma	64	Lymphoma, lung adenoma and luteoma
67				64	
69		+		70	
69			Lung adenoma	70	Lung adenoma
72			Lung adenoma		
84			Lung adenoma and mammary cancer	77	
84			Lymphoma and lung adenoma	80	

Lymphomas, lung adenomas and mammary cancer occurred in mice treated with the dye and in others injected with arachis oil alone (Table 1); but in the latter no local sarcomas and no intestinal tumours were found.

The livers of mice treated with 1-(2-tolylazo)-2-naphthol showed no proliferative changes. This is in contrast with Peacock's experiment where hepatomas, but no other type of tumour, were induced with the closely related chemical 1-benzeneazo-2-naphthol. In the present experiment the dye was given by subcutaneous injection of an oily solution. It seems unlikely that its carcinogenic activity would be suppressed if it were given by mouth, a point which is already under test. Therefore the use of the dye (oil orange *TX*) as a food colorant should be discontinued.

A Brain Extract as a Substitute for Platelet Suspensions in the Thromboplastin Generation Test

THE test described in 1953 by Biggs and Douglas[1] has proved a valuable technique for the study of the generation of plasma thromboplastin, and in the diagnosis of the various hæmorrhagic states due to defects at this level. Of the three ingredients for the 'incubation mixture', as originally described, only the preparation of a consistently satisfactory platelet suspension is troublesome and time-consuming enough to cause difficulties for those not constantly using the test. We have devised a modification, which we feel allows a higher degree of accuracy, as well as solving this problem and eliminating the need for siliconized glassware.

A standard human brain thromboplastin, prepared by acetone drying, is further washed with acetone until free of cholesterol, as judged by a negative Liebermann–Burchardt reaction. When 1 gm. of the dried powder is extracted at room temperature with approximately 50 ml. of chloroform, more than 300 mgm. of active material is obtained by evaporation of the filtrate. This gummy residue is finely homogenized in 50 ml. of 0·85 per cent sodium chloride. An approximately 1 : 100 saline dilution of this concentrate, substituted for the platelet suspension, gave 'peak' times of 10 ± 1 sec. in thromboplastin generation tests of plasmas and sera from twenty normal individuals; as with platelets,

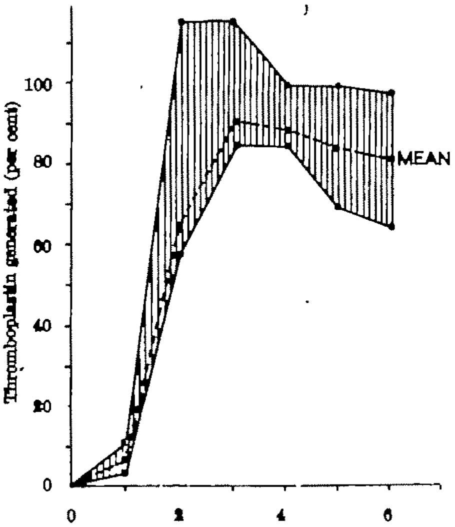

Fig. 1. Shaded area indicates range obtained with plasma and serum of each of twenty normals and same batch of extract 1 : 100

this 'peak' is reached in 3–5 min., and the optimal 'alumina' plasma and serum dilutions are 1 : 5 and 1 : 10 respectively, as recommended by Biggs and Douglas.

When frozen, the concentrated saline suspension remains stable for at least twelve months; it may be thawed and re-frozen repeatedly without loss of activity. The exact dilution for use should be determined for each batch of extract.

This modification was evolved in the process of work[2] on an extract for therapeutic use in thrombocytopenic states. It has proved entirely satisfactory in the diagnosis of hæmophilia and Christmas disease.

Influence of Ethylenediamine-tetra-acetic Acid on the Excretion of Zinc by the Rat

The administration of ethylenediamine-tetra-acetic acid (versene, sequestrene) causes increased urinary excretion of calcium, iron, lead and other metallic ions[1]. We became interested in this chelating agent as a possible means for reducing zinc stores and thus hastening the onset of deficiency in rats maintained on a diet low in zinc. Information on the effect of ethylenediamine-tetra-acetic acid on zinc metabolism was also required in planning an investigation of the excretion of recently absorbed zinc-65. Stability constants indicate[2] that zinc forms one of the most stable complexes with ethylenediamine-tetra-acetic acid, but we are not aware of any previous experiments to test its action on body stores of zinc, apart from a brief reference to unpublished work by Mager[3].

The present report concerns a preliminary investigation of the effect of ethylenediamine-tetra-acetic acid on the urinary excretion of zinc in rats. The calcium disodium salt of ethylenediamine-tetra-acetic acid was injected intraperitoneally into young adult male rats in doses of 100 mgm. per kgm. daily for three days. In experiment 1, four rats were kept in a stainless steel metabolism cage and the pooled urine collected each day for 18 hr. after the injection, and once for the following 6 hr. A control sample was collected on the day before injections began. During the control period and the first test period, the rats received distilled water but no food. Thereafter, a synthetic diet (modified from Day and McCollum[4]) containing less than 0·5 μgm. zinc per gm. was supplied continuously. In experiment 2, the animals received Purina Fox Chow (75 μgm. zinc per gm.) during the daily 6-hr. feeding period and were kept in the metabolism cages, with water but no food, for the 18-hr. collection period. Two groups of four rats each were used. Control samples were collected for three days previous to the injection of ethylenediamine-tetra-acetic acid. Results of urine zinc analyses by the method of Vallee and Gibson[5] are given in Table 1.

Table 1. Influence of Ethylenediamine-tetra-acetic Acid on Urinary Excretion of Zinc

Sample	Collection time (hr.)	Mean urine zinc (μgm. per rat) Exp. 1	Exp. 2
Control	18	2·2	3·8
EDTA, 1st day	18	68·5	37·1
EDTA, 2nd day	18	69·5	61·0
Remainder of 2nd day	6	1·8	—
EDTA, 3rd day	18	156·2	75 7

Controls: Exp. 1: Urine from four rats collected for one 18-hr. period. Exp. 2: Urine from eight rats collected for three 18-hr. periods.

Tests. Exp. 1: 100 mgm per kgm CaNa$_2$EDTA per day—1st day in 5 per cent, 2nd and 3rd days in 2·5 per cent solution; Exp. 2: 100 mgm. per kgm. CaNa$_2$EDTA per day in 0·83 per cent solution.

Intraperitoneal injection of the calcium disodium salt greatly increased urinary excretion of zinc. Very little zinc is normally excreted in the urine, and the range of values observed in experiment 2 was 1·6–5·9 μgm. zinc per 18 hr. Zinc mobilization occurred immediately after injection of ethylenediamine-tetra-acetic acid, and from the one determination for the final 6-hr. period in experiment 1, it seems that little excess zinc was excreted after the 18 hr. following injection.

After the last collection period, the following tissues from experiment 1 were analysed for zinc: stomach, ileum, pancreas, kidney, testis, epididymis, dorsolateral prostate, bone (tibia) and blood. All tissues except ileum and pancreas gave results within the normal range for rats fed on Purina Fox Chow—the diet of these rats before the experiment began. Ileum zinc approached that found in rats maintained for 5–8 weeks on the zinc-deficient diet (Table 2), while pancreas zinc in three out of four cases was equal to that found in such zinc-deficient rats. The reduced zinc concentration in pancreas and ileum was not unexpected, since zinc excretion normally occurs via the pancreas[6] and alimentary canal. The reduced intake and increased urinary excretion would decrease the need for this excretion route and thus lower the concentration of transient zinc.

Table 2. Effect of Ethylenediamine-tetra-acetic Acid on Zinc Content of Ileum and Pancreas

Treatment and diet since weaning	Ileum No. of rats	Ileum Mean Zn (μgm. per gm.)	Ileum S.E. of mean	Pancreas No. of rats	Pancreas Mean Zn (μgm. per gm.)	Pancreas S.E. of mean
Controls						
Zinc-deficient	10	19 7	±1 8	6	18 5	±1·2
Deficient + 100 μgm. zinc per day	14	37·2	±2 6	12	25·7	±1·4
Fox chow	13	28·7	±1·7	10	23·9	±0·7
EDTA injection						
Fox chow; zinc-deficient for 3 days	4	20 7	±2 9	4	18 1	±3·1

Controls are mean values from unpublished experiments.

Histochemical Adaptation of Aryl Iodosoacetates

It has been possible to obtain cleavage of the 1,2 glycol linkage in tissue sections with a solution of phenyl iodosoacetate in glacial acetic acid[1], thus duplicating histochemically the chemical studies of Criegee and Beucker[2]. However, to establish definitely the reliability of aryl iodosoacetates as histochemical reagents, it was felt that several other compounds of this type should be examined in a similar manner.

Four aryl iodosoacetates were prepared by Willgerodt's general methods[3], namely, *p*-nitrophenyl iodosoacetate, *p*-tolyl iodosoacetate, *m*-tolyl iodosoacetate, 2,4 xylyl iodosoacetate. These compounds were then tested histochemically for 1,2 glycol cleavage using formalin-fixed sections (paraffin technique) of rat and rabbit intestine and kidney. Concentrations of these compounds in glacial acetic acid were used ranging from 0·001 *M* to saturation, with oxidation periods of 15 min.–3 hr. All reactions were performed at room temperature (27° C.), and the aldehyde radicals resulting from the cleavage were stained with leucofuchsin. The 0·02 *M* solutions suggested by Pausacker[4] for chemical cleavage of *iso*hydrobenzoin and used in the phenyl iodosoacetate experiments appeared to be the concentration of choice, while the period of optimal oxidation was between 1 and 2 hr. The histological picture was similar to the one obtained with phenyl iodosoacetate and resembled that of lead tetraacetate[5] although weaker and less precise.

These experiments would appear to indicate that aryl iodosoacetates as a group are adaptable to histochemical procedures, and although their use is still academic, they may be of value to histochemistry in due course.

These experiments were made possible through a research grant by the Biological Stain Commission.

Chromatography of Tissue Histamine

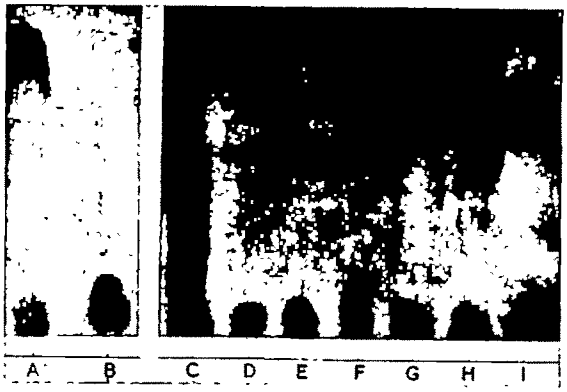

Fig. 1. Chromatograms developed with Pauly diazo-reagent for histamine. (*A*) Extract of dog mastocytoma in 10 per cent trichloracetic acid; (*B*) solution of histamine (100 μgm.) in water; (*C*) solution of histamine (100 μgm.) in 10 per cent trichloracetic acid; (*D*) solution of histamine (100 μgm.) in *N*/3 hydrochloric acid; (*E*) solution *C* after ether extraction; (*F*) solution of histamine (30 μgm.) in 10 per cent trichloracetic acid; (*G*) solution *F* with 300 μgm. arginine added; (*H*) solution *G* after ether extraction; (*I*) solution *F* with 100 μgm. each of arginine, lysine and ornithine added

Extracts of tissues exceptionally rich in histamine, such as ox pleura, ox liver capsule, and mast cell tumours from dogs[1], were prepared for ascending chromatographic estimation of histamine by simple extraction or by grinding the tissues with 10 per cent aqueous trichloracetic acid and centrifuging. Using as solvent mixture *n*-butanol : acetic acid : water (4 : 1 : 5), we observed that after spraying with the Pauly or the paranitraniline diazo-reagent two sharply defined spots appeared on the chromatogram of $R_F = 0 \cdot 11$ and $0 \cdot 65$ (Fig. 1,*A*). Both spots contained material which when eluted with water or 0·01 *N* hydrochloric acid showed histamine activity on the isolated guinea pig ileum and on the blood pressure of the atropinized cat. Prior removal of the excess trichloracetic acid from the solution by ether extraction merely reduced the intensity of the fast-running spot. When an eluate of this fast-running spot ($R_F = 0 \cdot 65$) was re-run in the same solvent as before, the histamine now remained entirely in its lower location ($R_F = 0 \cdot 11$).

At least three factors appear to be involved in the migration of histamine to the fast-running spot, namely: (1) the concentration of trichloracetic acid; (2) the concentration of histamine; (3) the presence of a basic amino-acid. First, pure histamine acid phosphate in water forms a compact spot at $R_F = 0 \cdot 11$ (Fig. 1,*B*), but with increasing concentration of trichloracetic acid a 'trail' of histamine moves up the paper as far as the $R_F = 0 \cdot 65$ area (Fig. 1,*C*). This is not a mere *p*H effect, for histamine in 0·33 *N* hydrochloric acid (Fig. 1,*D*) or in 10 per cent aqueous acetic acid does not migrate in this way. Trifluoracetic acid resembles trichloracetic acid in its mobilizing effect on histamine, recalling the similar effect of these acids on the chromatographic behaviour of adrenaline[2]. Removal of the excess acid from these solutions by ether extraction concentrates the histamine into a single compact spot at $R_F = 0 \cdot 11$ (Fig. 1,*E*). Secondly, when the strength of the trichloracetic acid is kept constant, any increase in concentration of histamine in the mixture is followed by increased upward trailing from the slow-running spot (Fig. 1, cf. *C* and *F*). Thirdly, for complete separation of the two spots, the presence of at least one basic amino-acid is necessary. When an artificial mixture is made up containing pure histamine, trichloracetic acid and arginine, lysine or ornithine, the chromatographic pattern now exactly resembles that seen with tissue extracts, the histamine being divided between the two spots, $R_F = 0 \cdot 11$ and $R_F = 0 \cdot 65$ (Fig. 1,*G*); ether extraction of this mixture simply reduces the intensity of the fast-running spot (Fig. 1,*H*). When all three amino-acids are present in the mixture, the chromatogram shows inversion (Fig. 1,*I*).

It is thus possible that the remarkable ability of trichloracetic acid to extract histamine from tissues is related not only to its coagulative effect on protein but also to its participation in a loose complex containing histamine (probably as the trichloracetate) and basic amino-acids. Detailed analysis of the original tissue chromatogram shows that arginine and lysine are in fact present and trail behind the fast-running spot of histamine.

Fluorescent Substances in Chromatograms of a Mutant Stock of *Drosophila*

In chromatograms prepared from various *Drosophila* organs and from whole flies, seven different ultra-violet fluorescent substances have been described[1,2]. The concentrations of these substances were shown to vary in different mutant stocks of the fly. Flies carrying recessive mutants in the heterozygous state could be distinguished from wild-type homozygotes on the basis of their fluorescence patterns[3,4].

It seemed of interest to determine whether the characteristic features in the chromatogram of a mutant stock depend on the major mutant gene it carries, or whether other genetical factors may be involved in their determination. This investigation was based on an *ey*^{2} stock of *D. melanogaster*.

Chromatograms were prepared on Whatman No. 1 paper, by squashing the severed heads of female flies (age at least four days), which had been briefly immersed in 96 per cent alcohol and afterwards boiled for 2½ min. in distilled water. For preliminary examinations, one-dimensional ascending chromatograms of various lengths were developed in propanol – ammonium hydroxide. For quantitative determinations, two-dimensional ascending chromatograms of 29 cm.^{2} were developed in a dark room in butanol – acetic acid – water in the first dimension and in water-saturated collidine in the second dimension. Twelve heads of the wild-type laboratory stocks or fourteen heads of the *ey*^{2} stock were used for one two-dimensional chromatogram. All *ey*^{2}-flies utilized possessed eyes of reduced size. Animals entirely devoid of eyes frequently appear in the stock, but these were not analysed. The ultra-violet fluorescent spots were identified in the chromatograms by the light of a lamp with maximum radiation at 365 mμ. These spots and blanks of corresponding sizes, having received identical solvent treatment, were eluted in the dark room in 3 c.c. of distilled water each. The fluorescence of the solutions obtained was measured with a Farrand fluorometer using filters of maximum transmittance at 366 mμ and 440 mμ as primary and secondary, respectively.

The *ey*^{2} stock differed from two laboratory strains (Berlin and Canton *S*) in three fluorescent spots, which are here designated by the symbols of Hadorn and Mitchell[1]. *Fl* 4 ('blue') was stronger, *Fl* 5 ('yellow') was weaker and *Fl* 7 ('yellow') appeared much fainter than in the wild-type flies.

Males of *ey*^{2} stock were crossed to virgin females of each wild strain. The *ey*^{2} males obtained in the F_2 generation were again mated to virgins of the appropriate wild stock. This procedure was repeated to the seventh backcross generation. The *ey*^{2} gene, the expression of which remained unimpaired, was thus gradually transferred to a background of genes and cytoplasm from the laboratory stocks. All cultures were kept at 26·5° ± 1° C. After the seventh backcross to the Berlin strain, allelism of the *ey*^{2} gene carried in the original stock with that of the modified line was confirmed by a test cross.

Starting with the F_2 of the fifth backcross generation, *ey*^{2} females with a Berlin background were utilized for chromatograms. Their one-dimensional fluorescent pattern was by then indistinguishable from that of the Berlin strain, whereas the original *ey*^{2} stock, under identical culture conditions, had preserved its distinctive features. Similarly, *ey*^{2} flies tested after the seventh backcross to Canton *S* had assimilated themselves to the Canton *S* pattern.

Fluorometric measurements were confined to *Fl* 4 and *Fl* 5. As in the experiments of Hadorn and Mitchell[1], these substances overlapped strongly in the first dimension. Their separation into distinct spots was achieved in the second dimension. In order to eliminate such differences in absolute quantities as might arise from the reduced size of the *ey*^{2} heads and eyes and from the variability in the eye size of the mutant, the ratio of the fluorometric values of *Fl* 5 to *Fl* 4 was determined for each chromatogram. Table 1 shows that the original *ey*^{2} stock differs significantly from the Berlin strain and from the *ey*^{2} with Berlin background. There is a small residual difference between the latter and the Berlin stock. Two sets of measurements carried out with the Canton *S* backcross series yielded comparable results.

Table 1. Ratios of Fluorometric Values *Fl* 5/*Fl* 4 in Chromatograms of Female Heads

	Berlin	*ey*^{2}	*ey* from sixth and seventh backcross to Berlin	Canton *S*	*ey* from seventh backcross to Canton *S*
Number of chromatograms	16	9	9	2	2
Ratio *Fl* 5/*Fl* 4 means	1·74	0 64	1·38	1·83	1 98
Standard error (σm)	±0 09	±0 03	±0 06	—	—

Significance of differences between:

	Berlin and *ey*^{2}	Berlin and *ey* on Berlin background	*ey*^{2} and *ey* on Berlin background
t	9·57	2 805	8·88
p	< 0·001	0·01	< 0 001

A reciprocal backcross stock is in preparation, utilizing *ey*^{2} females and Berlin males. It is hoped that this stock may furnish information on the importance of cytoplasmic or chromosomal factors in the determination of the fluorescent pattern.

In conclusion, it should be mentioned that the fluorescent characteristics of *ey*^{2} and of Berlin flies were differentiated autonomously in eye disks transplanted reciprocally between the two strains at the third instar, and in host eyes. This autonomy was demonstrated qualitatively in a series of chromatograms prepared from transplants (9–37) and from a corresponding number of excised host eyes (unboiled).

This investigation was started in the laboratory of Prof. Ernst Hadorn (Zurich), to whom I am indebted for advice and instruction. The fluorometric measurements were carried out by Dr. M. Finkelstein (Jerusalem), whose help is also acknowledged.

Instability of Milk due to a High Content of Calcium Ions

IN the nineteen thirties, great difficulty arose in the Netherlands from the frequent occurrence of flocculation of fresh milk on boiling and even during transportation or storing for a short time. This condition was called 'the Utrecht abnormality of milk', for it appeared first in the province of Utrecht. Afterwards this abnormality was found in other parts of the country as well[1]. The abnormality disappeared gradually; at present it is quite rare.

Milk exhibiting the Utrecht abnormality does not show any unusual value for the common numerical data (for example, *p*H, titration acidity, protein content, total calcium content). The bacterial count is normal. There was evidence, however, that the instability is caused by an abnormally high content of calcium ions[2]. But the evidence was only indirect, for at that time it was not possible to determine the calcium ion content. In recent years a reliable method for the determination of calcium ion content in milk ultrafiltrate has been developed[3,4].

In recent months we have had the good luck to obtain a few samples of milk showing the Utrecht abnormality.

The method of determination consists in using murexide (the ammonium salt of purpuric acid) as a calcium indicator and measuring with a Unicam *S.P.*500 spectrophotometer the change of colour due to the amount of calcium ion present. For full details of the method and its theoretical background refs. 3 and 4 should be consulted.

The results for four samples are listed in Table 1.

Table 1. ANALYSIS OF FOUR SAMPLES OF MILK SHOWING THE UTRECHT ABNORMALITY

	1	2	3	4	Normal range
*p*H	6·7	6·6	6·6	6·4	6·4–6·6
Titration acidity*	7·8	14·5	16·0	19	14–20
Heating test	+	++	+++	++	—
Alcohol test	+	++	+++	++	—
Total Ca (mgm. per cent)	176	144	216	184	120–200
Ultrafiltrable Ca (mgm. per cent)	44	34	45	54	20–46
Ca ions (mgm. per cent)†	14·8	15·2	20	27	8·0–14·4
Citric acid (mgm. per cent)†	161	74	122	208	96–288

* ml. of 0·1 *N* sodium hydroxide/100 ml. of milk.
† In the ultrafiltrate.

In complete accordance with Seekles's expectations[1], we have found the content of calcium ions to be significantly higher than normal.

A Toxic Effect of Fluoride

BECAUSE fluoride has been shown to depress bacterial activity, and because the bacteria of the intestinal tract synthesize several vitamins which are utilized by the host, it was considered that the ingestion of large amounts of fluoride might influence the onset of specific vitamin deficiencies in a manner comparable with the effect produced by the insoluble sulpha drugs or the antibiotics.

In one set of experiments large amounts of fluorine ingested orally were found to favour the initiation of a nutritional deficiency (probably a biotin deficiency) in rats under certain conditions. In this experiment 80 parts per million of fluoride, in the form of sodium fluoride, was added to the drinking water of the experimental group. The control group received no fluoride supplements. For three weeks the following semi-synthetic diet was fed: 75 per cent sucrose, 18 per cent vitamin-free casein, 4 per cent lard, 3 per cent salts. To each 100 gm. of ration the following vitamins were added: 1 mgm. thiamine, 1·5 mgm. riboflavin, 0·5 mgm. calcium pantothenate, 0·5 mgm. pyridoxine, 10 mgm. inositol, 10 mgm. *p*-aminobenzoic acid, 10 mgm. niacin, 10 mgm. 2-methyl naphthoquinone, 40 international units vitamin A, 200 mgm. choline chloride. No change in the weights or the appearance of the animals was observed.

The diet was then changed to include 16 per cent raw egg-white, 10 per cent casein, 67 per cent sucrose, 4 per cent lard and 3 per cent salts. The vitamin supplements were the same as listed above. The egg-white was added to aid the onset of a biotin deficiency. At the beginning of the period during which this diet was used, the average weights of the three rats of the control and experimental groups were 204 and 178 gm. respectively. After sixteen days the average weights were 196 and 125 gm. One of the rats of the experimental group died at this stage.

The fur of the experimental animals was bristled and rough, and there was alopecia of the snout, head and legs, mild diffuse dermatitis, and mild 'spectacle eye'. The control animals showed none of these symptoms.

This experiment was repeated and a similar result was obtained.

The diet used had a low vitamin A and pantothenic acid content. Increasing the vitamin A content to 200 international units slightly delayed the onset of the symptoms. Increasing the calcium pantothenate content to 2 mgm. per 100 gm. of ration did not affect the result.

The toxicity of the fluoride alone was not the cause of these symptoms, because other experiments revealed that: (*a*) 120 p.p.m. of fluorine in the drinking water did not affect the growth of rats during a seven-week period, when a natural stock diet was fed; (*b*) if the egg-white was excluded from the diet shortly after the loss of weight began, there was no further loss of weight even though the fluoride supplements were continued.

The deleterious effects described above must have been due to either a nutritional disturbance, possibly a biotin deficiency complicated by other factors, or an unknown form of toxicity resulting from the use of egg-white and fluoride during the same period. Space will not permit a discussion of the evidence for and against each hypothesis. However, in support of the former is the fact that the deleterious effect of the egg-white – fluoride combination did not occur when the egg-white was added to a natural stock diet.

In a second set of experiments large amounts of fluoride ingested orally were found not to affect the severity of riboflavin deficiency. In this work 200 p.p.m. of fluoride as calcium fluoride and 120 p.p.m. as sodium silicofluoride were included in the semi-synthetic diets of two groups of young rats. The diet was deficient in its riboflavin content. After five weeks the average weights of the animals of the control group, which had received no supplementary fluoride, and the experimental groups were approximately the same.

A similar result was obtained when fluoride was added to a diet which was deficient in pantothenic acid.

The results of further experiments which have recently been begun should help clarify the problem presented in the first experiment.

This work will be published in detail at a later date.

Toxicity and Narcotic Activity of Fluorocarbons

Published information on the results of investigation of the toxic and narcotic activity of fluorocarbons is very scanty, and such as is available is probably invalidated because of the lack of purity of the samples used in the tests. Struck and Plattner[1], who examined C_4F_{10}, C_5F_{10} and C_6F_{12}, concluded that the materials were toxic, whereas Spiegl[2] used concentrations of C_7F_{16} and C_8F_{18} which were too low to acquit them of toxic properties. He found C_7F_{14}, of unspecified purity, to be toxic.

We have examined the physiological activity of a sample of C_7F_{14}; this had been subjected to exhaustive washing with methyl alcohol, which is known to be an excellent selective solvent for hydrofluorocarbons[3]. When tested against grain weevils by the method described by Bradbury and Armstrong[4], the compound was non-toxic and virtually devoid of narcotic activity (8 per cent knockdown after 4 hr. exposure to a thermodynamic concentration of 0·8). In a 24-hr. test, there was very slight narcosis (39 per cent at 0·9) and only 10 per cent mortality. Tests with mice at thermodynamic concentrations of 1·0 showed no narcosis and no signs of toxicity in a 1-hr. test. There were no delayed deaths.

Mullins[5] has recently referred to experiments with C_8F_{16} on mice, which failed to show either toxic or narcotic action at a thermodynamic concentration of 1·0 for 1-hr. exposures.

We believe that the results of Mullins and ourselves represent the first unequivocal evidence that fluorocarbon vapours are non-toxic when the impurities have been removed to sufficiently low limits. The unsuitability of fractionation for this purpose when applied to fluorocarbons has been emphasized by Grafstein[6] and is consistent with our experience.

The almost complete absence of narcotic activity is also noteworthy. The results obtained with C_7F_{14} may be compared with those for C_7H_{14}, which gave a 50 per cent knockdown at a thermodynamic concentration of 0·1 in a 2-hr. test with grain weevils. Ferguson[7] has similarly shown that heptane, C_7H_{16}, exhibited threshold narcosis at a concentration of 0·15 and complete narcosis at a concentration of 0·25.

It is hoped to publish a full account of this work elsewhere. We wish to thank Dr. J. Raventos, of I.C.I. (Pharmaceuticals), Ltd., for carrying out the tests on mice.

Differential Thermogravimetry

The methods of differential thermal analysis and thermogravimetry have been used in parallel for thermal investigations of analytical precipitates[1]. This double method possesses obviously the advantage that the same thermal change can be observed and characterized by the loss of weight and the change of temperature simultaneously, the two sets of measurements checking each other, or indicating by differences of results some changes which could not otherwise have been observed. In addition, the differential thermal analysis method completes the thermogravimetry measurements in the case when no loss of weight occurs. On the basis of thermogravimetry results, accurate quantitative conclusions may be drawn, which can scarcely be made with thermograms obtained by differential thermal analysis. During our investigations materials have also been studied which, for some reason (for example, melting), could not be subjected to differential thermal analysis. This gave rise to the idea of a differential thermogravimetric method and we succeeded in developing and applying this procedure.

Our thermobalance has been constructed of an air-damped automatic analytical balance. To the beam of this a permanent magnet has been attached, which moves inside a symmetrically placed coil with a very large number of turns. On decomposition of the specimen the beam of the balance moves and causes the displacement of the permanent magnet. The

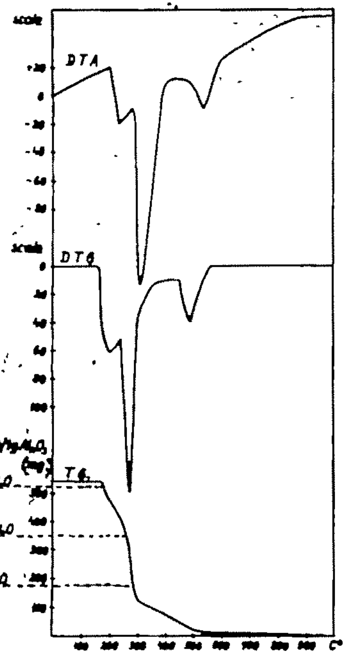

Fig. 1. Gibbsite (hydrargillite)

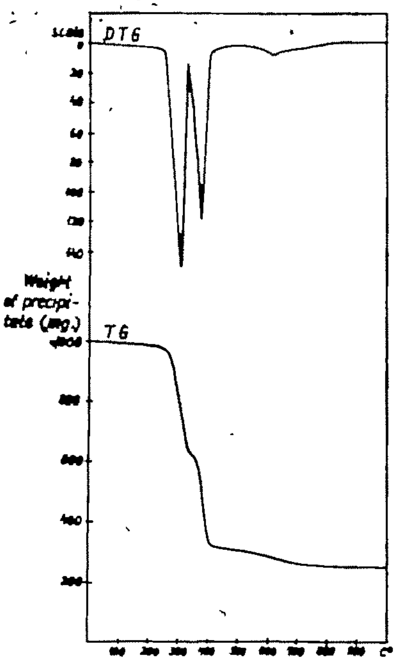

Fig. 2. Zinc anthranilate

rate of motion of the magnet corresponds to that of decomposition, and consequently a current proportional to the change of weight is induced (dm/dt). This latter is measured by means of a sensitive mirror galvanometer. Registering the values of deviations observed on the galvanometer as a function of oven-temperatures, the thermograms shown in Figs. 1 and 2 have been obtained. Fig. 1 shows differential thermal analysis (*D.T.A.*), differential thermogravimetric analysis (*D.T.G.*) and thermogravimetric analysis (*T.G.*) curves for gibbsite (hydrargillite), while Fig. 2 shows differential thermogravimetric analysis (*D.T.G.*) and thermogravimetric analysis (*T.G.*) curves for zinc anthranilate.

The many advantages of the differential thermogravimetric method may be summarized as follows.

(1) It can be carried out together with thermogravimetric measurements.

(2) The curves for differential thermal analysis and differential thermogravimetric analysis are comparable, but the results by the former method indicate even those changes of state which are not accompanied by loss of weight. The curves obtained by the latter method reflect only changes in weight, but are more reproducible.

(3) While the curves for differential thermal analysis extend over a wider temperature interval, due to the subsequent warming of the material after reaction, the differential thermogravimetric measurements indicate exactly the temperatures of starting, the maximum rate and the end of the change, and give a most attractive picture of the whole process.

(4) On the thermogravimetric curves, changes following each other immediately cannot be distinguished, as the corresponding stages coincide (Fig. 2). The differential thermogravimetric curves of the same change indicate by sharp maxima that the thermogravimetric stages can be divided in two parts.

(5) The differential thermogravimetric curves are exactly proportional to the derivatives of thermogravimetric diagrams; therefore the area under the curve gives the change of weight precisely, in contrast to the differential thermal analysis curves, where the corresponding area depends also on other factors (for example, heat conductivity, heat of translation, solidity). Accordingly, differential thermogravimetric curves enable one to make exact quantitative analyses.

(6) The method can be used for the investigation of materials which for some reason or other cannot be analysed by the differential thermal analysis method. For example, some organic compounds melt during heating, but even so, differential thermogravimetric methods yield fairly good results.

Very recently, a similar method was described by W. L. De Keyser[2] for determination of the rate of decomposition of some materials. While his method is interesting, objections can be made to its theoretical basis, for the method gives only the ratio of the finite increments of a thermogravimetric curve, whereas by our method—in the case of uniform heating—the derivative dm/dt can be obtained.

The results of our investigations will be published in detail in the *Acta Chimica* of the Hungarian Academy of Science.

A Mechanism for the Displacement of Ions in an Ionic Lattice

The most direct way by which an ion can be displaced in an ionic lattice when the lattice is subjected to ionizing radiation is through simple collision displacements. Thus high-energy electrons can be expected to produce displacements by simple 'billiard-ball' collision; γ-rays can possibly produce displacements by Compton scattering, either by direct recoil of the ions or by producing high-energy electrons which afterwards collide with and displace ions.

Some displacement experiments I have carried out are difficult to interpret solely on a 'billiard-ball' collision mechanism. In these experiments alkali halide crystals have been bombarded with high-energy electrons giving coloration of the crystal. Some of the colour centres induced are stable against subsequent irradiation with white light, the remainder are unstable. After optical bleaching, it is observed that the crystal is 'permanently' coloured to some depth below the crystal face on which the bombarding electrons were incident. The depth of coloration increases with increasing energy of the incident electrons, but the intensity of the coloured region is very much greater than would be the case if each bombarding electron produced one colour centre.

Moreover, for Rutherford scattering, the collision cross-section for producing displacements (high-angle scattering) approaches zero as electrons lose energy in passing through the crystal, for the smaller the incident electron energy the more nearly must the collision be 'head-on' to produce a displacement. The intensity of the coloured region might thus be expected to fall off steadily to zero with increasing distance from the incident crystal surface. In actual fact, observation shows that the intensity is of the same order throughout the depth of the coloured region and that the colour ceases quite abruptly.

To account for these features the following simple mechanism for producing displacements by any form of ionizing radiation is postulated. The incident radiation, high-energy electrons or high-energy photons (X-ray, γ-ray and possibly even ultra-violet light), ionizes the negative ions in the ionic lattice, stripping these ions of several and at least more than two electrons. The stripped electrons move through the crystal, possibly themselves producing further ionization of negative ions, and eventually become trapped either at negative-ion vacancies in the crystal or by halogen ions which are short of electrons as a result of their ionization. These stripped negative ions, which are now positively charged, are sitting uncomfortably surrounded by positively charged nearest neighbours and will be displaced into interstitial sites by the induced high Coulomb repulsive force. Such displacement may be expected to occur in a time which is of the order of a few atomic vibrations, provided that the recombination time for the recovery of the electrons by the stripped negative ions is sufficiently long ($\sim 10^{-11}$ sec.).

The Coulomb repulsion between these stripped negative ions and their environment will be less unfavourable in these interstitial sites. Here the ions will recover all but one of the electrons which were originally lost, so becoming electrically neutral. Provided that thermal activation does not restore the displaced ions from trapped sites to normal lattice sites, the remaining electron will be trapped in a negative ion vacancy. This gives rise to a colour centre which cannot be optically bleached at low temperatures (room temperature for sodium or potassium chloride, etc.).

It will be observed that such a mechanism is of mportance only if: (1) the lattice bonding is eteropolar; (2) the recombination time for the ipped electrons is long compared with the time of attice vibration; (3) the cross-section for multiple ization is large enough to produce an appreciable ct.

Condition (3) is justified for electron bombardment, smuch as cross-sections for multiple ionization crease approximately by an order of 10 for each unit rease in the degree of ionization. Thus single nization by electrons has a cross-section of the order f 10^{-14} cm.^{2}, double ionization 10^{-17} cm.^{2} and so on[1].

The number, n, of interstitial atoms per c.c. produced as a result of this ionization displacement mechanism is given by:

$$n = N_0 F t \sigma,$$

where σ is the ionization cross-section for multiple ionization, N_0 is the number of ions per c.c., F is the flux number of incident particles per cm.^{2} per sec., and t is the time of exposure in seconds.

Taking $\sigma \sim 10^{-19}$ cm.^{2} (fourfold ionization), it will be seen that the number of displacements per unit volume per unit integrated flux (Ft) is $\sim 1{,}000$. Thus for every incident electron per square centimetre, $\sim 1{,}000$ displacements per c.c. are produced, and this will produce a colour far more intense and uniform throughout the electron range than would be formed by a simple collision process. Any form of ionizing radiation should be capable of producing displacements by this mechanism, the magnitude of the effect depending upon the cross-section for multiple ionization and the intensity of the ionization. For example, this simple mechanism may explain the mechanical hardening of alkali halide crystals by X-rays[2].

Finally, it will be realized that if such a mechanism for producing displacements is accepted, the magnitude of the effects of radiation damage will depend markedly upon the type of radiation used and also upon the characteristics of the atomic binding forces within the crystal. For example, electron bombardment may produce considerably more damage than neutron bombardment per incident particle; again, under electron bombardment, more damage may be expected in the case of an intermediate phase in a metal alloy system in which the bonding is largely ionic and the recombination time long, than in the case of a simple solid solution or a pure metal.

I wish to acknowledge helpful discussions with Dr. W. M. Lomer and Mr. R. A. Dugdale.

Electronegativity and the Stability of Metal Complexes

Various workers[1] have remarked on the order of stability for metals with the same complexing agent. Thus, with salicylaldehyde in 50 per cent dioxan, the order is Pd > Cu > Ni > Pb > Co and Zn > Cd > Mg, and is the same for glycine and 8-hydroxy quinoline. A further list is Cu > Ni > Zn > Pb > Co > Mn > Mg > Ca > Sr > Ba based on considerations of glycine, alanine, glycyl-glycine and several carboxylic acids[2].

However, in a critical review of the available data, Irving and Williams[3] conclude that there is only one order of stabilities, which holds almost without exception for all complexes: Mn < Fe < Co < Ni < Cu > Zn. Earlier[4], they had pointed out that this particular order of stabilities could be intelligibly correlated with the second ionization potential. Ackermann[5] had also suggested correlation with the sum of the first two ionization potentials and that the electron structure of the metal in the chelate somehow resembled that of the metal in the elementary state.

Mellor and Maley[1] briefly considered the significance of ionic radius and electronegativity in discussing the

Table 1

Metal	Electronegativity (Haissinsky)	Metal	Electronegativity (Haissinsky)
Ba	0·85	Co	1·7
Ca	1·0	Ni	1·7
Sr	1·0	Cu	2·0
Mg	1·2	Zn	1·5
Mn	1·4	Cd	1·5
Fe	1·65	Pd	2·0

empirical order of stability which included elements such as cadmium, palladium, lead, magnesium, etc., but did not observe any clear correlation between complex stability and ionic radius or any other parameter which might be related empirically.

An empirical relation has now, however, been found to exist between electronegativity values as calculated by Haissinsky[6] and the stability of metal complexes. These electronegativity values calculated in an analogous manner to that of Pauling[7] from thermochemical data are shown in Table 1.

It will be observed that the order of stability given by Irving and Williams[3], namely, Mn < Fe < Co < Ni < Cu > Zn, is practically identical with the electronegativity order for the same metals, namely, Mn < Fe < Co = Ni < Cu > Zn. The 'significant' rise of ionization potential ($I_1 + I_2$) to a maximum at copper and fall at zinc, observed by Irving and Williams, is also observed with these electronegativity values. Further, a plot of log stability constants of a typical complexing agent, glycine[8], against the appropriate electronegativity values of the metals gives rise to a smooth curve (Fig. 1). Similar curves have been obtained for malonic acid, oxalic acid, ethylene diamine and alanine. This shows that complex stability is a continuous function of the electronegativity difference between metal and ligand. It appears also that metals other than those in the Irving–Williams's invariable-order list, for example, calcium and barium, fit the correlation. The slopes of the curves vary with the ligand, ethylene diamine being greater than glycine which is greater than oxalic acid. This fact is also in agreement with the general correlation of greater stability of complex with decrease in difference of electronegativity of metal and ligand.

That there should be a relationship between complex stability and electronegativity is reasonable, since the strength of any molecular bond is almost certainly a function of the electron-attracting power of the atoms in the bond, and it is probably significant that the values of the Walsh force-constant electronegativities[9] for the transition metals show the same rise in value to a maximum at copper and fall at zinc as do the Haissinsky values. In addition to this, electronegativity difference is related to the amount of covalent character of the metal–ligand bond[10] and thus complex stability is also related to covalent character.

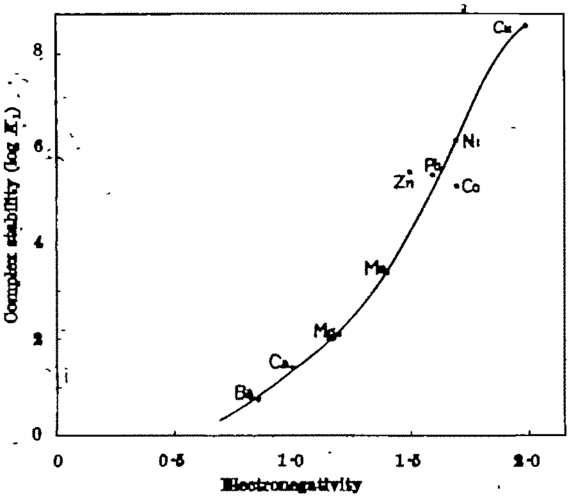

Fig. 1

From this new correlation with stability, it would seem possible to state that the stability of a metal complex in solution, and for a given ligand, is determined by two main influences: (*a*) the tendency towards or ease of formation of the complex, as governed by, for example, the second ionization potential; and (*b*) the strength of the metal–ligand bonds after complex formation, as governed by the electronegativity difference of metal and ligand. Other influences such as steric effects may also play their part, while hybridization, inductive effects, etc., in certain cases will influence the effective electronegativity difference, and hence influence the stability of the complexes.

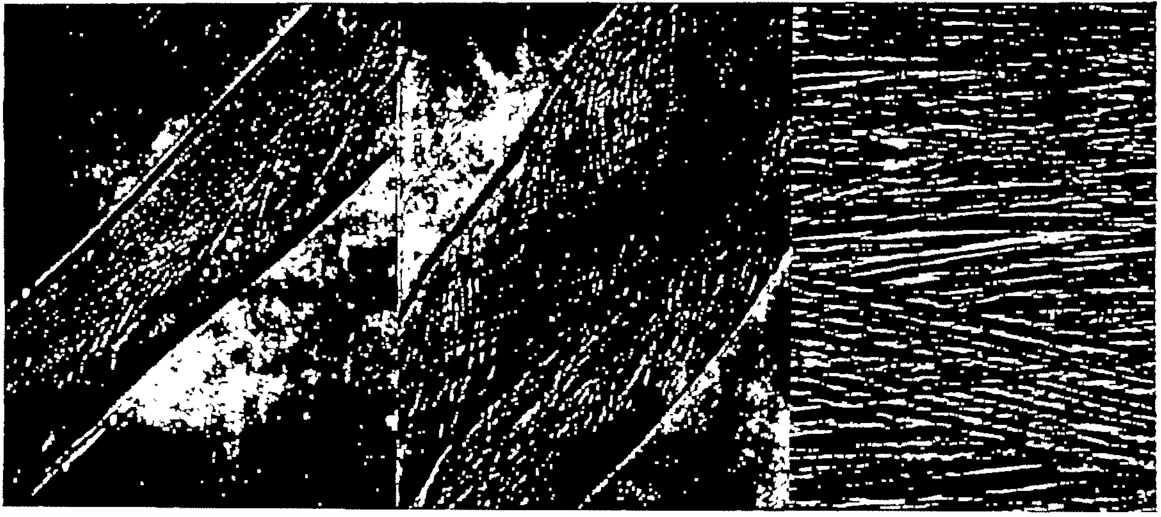
Effects of Pressure upon Collagen

During recent investigations into the microstructure of collagen fibres, we have utilized the 'crushing technique' of Boddy[1], and combined this with the interferometric method due to Merton[2]. By these means, changes in structure due to physical or chemical effects may be readily observed, and we have found that liquid globules are exuded from air-dried collagen fibre bundles under pressures in the region of 2,500 kgm./cm.^{2}. Fig. 1 shows the appearance of a fibre bundle originally 35 μ in diameter after the application of a load of approximatel 2,000 kgm./cm.^{2}. The globules are seen on the surfa and at the edges of the bundle. These appear discrete globules after the release of the pressu if it has been sufficient to force the film of displa liquid to an excessive distance. The effect of increas the pressure to approximately 2,500 kgm./cm.^{2} shown in Fig. 2, where the displaced liquid continu to 'wet' the fibres at the perimeter of the ma pressure area. The portions of fibres from whi liquid has been displaced appear dark as they a virtually dry-mounted. Further work is in progress upon the nature of this liquid.

It is possible that the loss of moisture on drying which contracts the fibres and allows them to coalesce into a more or less homogeneous bundle is never com-



Collagen fibre bundle (1) after pressure has been applied, showing globules of liquid; (2) after great pressure has been applied; (3) dried before applying pressure

plete. Thus, even in the so-called dry state, the fibres possess surface films which prevent structural dissociation of the constituent fibrils and ensure the preservation of fibre identity. Continued increases of pressure expand the bundle by increasing its width and may involve rupture of fibres with splitting of the bundle if dry fibre bundles are used. It has been noted that there is a significant elastic contraction after removing the pressure, and further plastic flow of material on re-applying the loads. A point can be reached at which the elastic contraction ceases.

Fig. 3 illustrates the effects of crushing a fibre bundle containing sufficient moisture to allow the fibrils to separate; a 35-μ diameter bundle can be reduced to a unit layer of constituent fibres about 1·5 μ thick (that is, the diameter of the fibre).

Similar exudation effects have been obtained with other fibres and with tanned collagen from leather. In this case, the exudate contains oils or fats as well as moisture. Full reports on this work will appear elsewhere, but it is thought the release of what may be more or less chemically bound water by mechanical pressure may be of interest in the study of surface films and conditions on fibres.

We shall be interested to know if this has been observed under other conditions.

Radiation Dosimetry of Iodine-132

FISSION product tellurium-132 (half-life 77 hr.) is w obtainable from the Atomic Energy Research tablishment, Harwell. The daughter isotope odine-132 is potentially valuable in a variety of tracer applications, such as double tracer experiments in conjunction with 8·0-day iodine-131 or in short-term physiological studies where minimal radiation dosage is desired[1]. The measurements reported here provide the necessary physical data for the calculation of the radiation dosage resulting from the use of iodine-132 in biological tracer investigations[2].

Tellurium-132 is obtained from the Atomic Energy Research Establishment as a dilute sulphuric acid solution containing potassium permanganate. The iodine-132 is conveniently separated as 'carrier-free' iodine by distillation following the addition of sufficient $N/10$ hydroxylamine hydrochloride to render the solution colourless. 4π β-counter measurements[3,4] indicate that longer-lived radioactivity, assumed to be due to iodine-131, accounts for less than 1 per cent of the initial radioactivity of the separated material.

The γ-ray dose-rate and total β-energy emission from iodine-132 have been measured by the ionization methods described by Gray[5]. The dose-rate at 1 cm. from 1 mc. of iodine-132 (measured by 4π β-Geiger–Muller counter) was found to be 12·1 r./hr. and the mean β-ray energy emitted per disintegration was 0·45 MeV. Collectively, these results imply a difference of approximately 3·3 MeV. between the ground-states of iodine-132 and its daughter nucleus, and this value should be correct within about 10 per cent irrespective of the precise details of the decay scheme.

The results were obtained by comparison with the γ-ray output of a radium needle, which had been carefully compared with a source held at the National Physical Laboratory, and this in turn had been calibrated there against the British Radium Standard. It was assumed that the γ-ray dose-rate from 1 mgm. of radium screened by 0·5 mm. of platinum is 8·3 r./hr. at 1 cm., and in deducing the β-ray energy emission it was further assumed that the mean energy required for the formation of 1 ion pair in air is 32·5 eV.

The β-ray energy measurement depends on the observation of the ionization in a cavity lined by a solution of the radioactive material in agar or gelatin. Corrections are applied for the effects of attenuation of the β-rays by the air in the cavity, for the limited thickness of the active lining, and for the ionization caused by the γ-rays from the lining. The chamber used had a lining 4 mm. thick, and the first two corrections were calculated on the assumption that iodine-132 has two β-rays of maximum energy[6] 2·2 and 0·9 MeV. It then follows from the experimental result that each of these contributes approximately 50 per cent to the total emission of β-ray energy. The combined correction for these effects was 4·3 per cent. The γ-ray correction, based on the measured value of 12·1 r./hr./mc. at 1 cm., amounted to 8·8 per cent.

A measurement of the half-life was made on a β-ray ionization chamber, and a regression line through seven points, spread over 8 hr., gave a half-life of 2·259 ± 0·003 hr. (after correcting for 0·7 per cent iodine-131 initially present as contaminant). This figure is subject to a systematic error not greater than about 0·005 hr. due to possible error in the chamber background.

We are grateful to Dr. G. B. Cook and Mr. J. D. Eakins, of the Isotopes Division, Atomic Energy Research Establishment, Harwell, for their co-operation and their advice on the separation of iodine-132, and to the Medical Research Council for the loan of the equipment used in the ionization measurements.

Successful Inter-breed Transfer of Ova in Sheep

Successful transfer of ova by surgical techniques in sheep has been reported by Warwick and Berry[1] and Lopyrin, Loginova and Karpov[2]. In our experiments, transfers of ova have been carried out between the Border Leicester (mature weight 140–180 lb.) and Welsh Mountain (mature weight 80–100 lb.) breeds in order to evaluate the maternal influence on the size of lambs at birth and at subsequent ages.

Thirty Welsh Mountain and twenty-five Border Leicester ewes were run with a raddled, vasectomized ram. Synchronization of the onset of œstrus in the majority of the ewes was attempted by means of progesterone treatment[3]. Four days before the expected onset of œstrus, the donors were treated with raw pregnant mare serum (stored at – 10° C.) and then run with a fertile ram of the same breed. The recipients remained with the vasectomized ram.

Laparotomy in the donors was performed 68–90 hr. after the onset of œstrus. *In vivo* recovery of the ova from the Fallopian tubes was carried out as described by Chang[4]. Either homologous blood serum or Ringer's solution was used as the flushing medium. The ova were transferred in a glass pipette which was inserted into the lumen of the uterine horn near the utero-tubal junction. Single ova were transferred to seventeen recipients and one ewe received two ova. After recuperation, the recipients were run with a fertile ram of the opposite breed.

One male and two female Border Leicester lambs were born to Welsh ewes, all requiring assistance at parturition, and five Welsh ewe lambs were born to Border Leicester ewes. The mean birth-weight of the Border Leicester lambs from the Welsh ewes was 11·1 ± 0·38 lb. after a mean gestation period of 146·0 ± 0·58 days, and that of the Welsh lambs from Border Leicester ewes was 9·5 ± 0·18 lb. after a mean gestation period of 149·6 ± 0·51 days. Birth-weights and mean gestation periods of Border Leicesters are normally 13·5–14 lb. and 145 days respectively, whereas the corresponding figures for the Welsh breed are 8–8·5 lb. and 147 days respectively.

Transfers were successful when œstrus in the recipients commenced from 16 hr. before to 20 hr. after that in the donors. Thirty-seven ova, representing 58 per cent of the ovulations, were recovered from thirteen ewes; the standard error of the recovery-rate was 20·2 per cent. Of the eight successful transfers, two were 4-cell, five 8-cell and one a 16-cell ovum. Four out of seven and four out of eleven transfers, using blood serum and Ringer's solution respectively, were successful. Prior to transfer to the recipients, seven of the ova which developed to term were exposed for 30–45 min. at room temperature, and one developed after exposure for 70 min.

Our results to date indicate that the influence of the size of the breed of the mother on birth-weight is marked, and that ovum transfer in the sheep can be as successful as in the rabbit[5].

Mechanical Separation of Plant Tissues

An investigation was recently carried out in this Laboratory into the best way of separating the fibre strands of various 'bast' and 'leaf' fibres into their component elementary cells. The fibres were first treated by the chlorite method[1] and then divided into two parts. One part was subjected to shaking with glass beads in a glass bottle, whereas the other part was shaken in a polythene bottle with short (about 2 cm.) lengths of glass rod covered with rubber 'policemen'. Microscopical examination showed that excellent separation was effected by the secon method without damage to the fibres, althoug damage was pronounced with the glass beads. It i possible that this method, which appears to be n generally known, may be capable of wider applicati for separating plant tissues.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 8

Manchester Literary and Philosophical Society (in the Reynolds Hall, College of Technology, Manchester), at 5.45 p.m.—Mr. T. M. Herbert: "The Application of Science in Railways" (Joule Memorial Lecture).

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Methods of Teaching Technical Writing".

Pharmaceutical Society of Great Britain (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Prof. G. Valette (Paris): "The Role of the Pharmacist in Phytopharmacy in the Present and the Future".

Tuesday, November 9

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. G. A. Wells: "The Stand Against Scientific History—Schopenhauer to Collingwood".*

British Ornithologists' Union (joint meeting with the Zoological Society of London, at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Dr. H. L. Løvenskiold (Norway): "The Birds of Spitsbergen".

Society for Cultural Relations with the U.S.S.R., Southampton Group (in the Senior Common Room, The University, Southampton), at 5 p.m.—Academician M. M. Dubinin: "Scientific Research in the U.S.S.R.".

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. J. A. Skinner and Mr. F. B. Martin: "Some Considerations of Airfield Pavement Design".

Royal Institute of Chemistry in collaboration with the Imperial College Chemical Society (in the Large Lecture Theatre, Chemistry Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Dr. Robert Neville Haszeldine: "Fluorocarbon Derivatives" (Meldola Medal Lecture).

Society of Chemical Industry, Chemical Engineering Group (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. H. C. S. de Whalley: "The Decoloration of Sugar Liquor by Solid Absorbents".

Institute of Physics, London and Home Counties Branch (at 47 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. H. M. Finniston: "The Materials of Atomic Energy".

Wednesday, November 10

University of London (at the Postgraduate Medical School, Ducane Road, London, W.12), at 2 p.m.—Dr. Barbara Clayton: "Laboratory Investigation in Endocrinology".*

Institute of Petroleum (at 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. B. W. Bradford, Mr. D. Harvey and Mr. D. E. Chalkley: "The Chromatographic Analysis of Hydrocarbon Mixtures".*

Institution of Electrical Engineers, Radio and Measurements Sections (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. L. Essen: "Standard Frequency Transmissions": Mr. J. McA. Steele: "The Standard Frequency Monitor at the National Physical Laboratory": Mr. H. B. Law: "Standard Frequency Transmission Equipment at Rugby Radio Station".

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. V. A. Ambartsumyan (U.S.S.R.): "Stellar Systems of Positive Total Energy".* (Further Lecture on November 11.)

Institute of Physics, Education Group (at 47 Belgrave Square, London, S.W.1), at 6 p.m.—Dr. F. Sherwood Taylor: "Galileo".*

British Psychological Society, Social Psychology Section (in the Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 8.15 p.m.—Dr. C. M. Fleming: "Education and Psychology".

Thursday, November 11

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. A. Charlesby and Mr. J. J. Polling: "The Optical Properties of Thin Oxide Films on Tantalum"; Mr. M. A. H. Lanyon and Mr. B. M. W. Trapnell: "The Interaction of Oxygen with Clean Metal Surfaces".

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Sir Alfred Egerton, F.R.S.: "Reflections on the Management of Heat". (Eighth Hinchley Memorial Lecture.)

Institution of the Rubber Industry (in the Lecture Theatre, Institution of Civil Engineers, Great George Street, Westminster, London, S.W.1), at 6 p.m.—Dr. E. J. Buckler: "Nitrile Rubbers".

Royal Aeronautical Society (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Dr. G. V. Lachmann: "Boundary Layer Control".

Society of Chemical Industry, Microbiology Group (joint meeting with the Agriculture Group, at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 6.15 p.m.—"The Present State of our Knowledge of Ruminant Digestion". Dr. A. E. Oxford: "Its Bacteriology and Protozoology"; Dr. A. T. Phillipson: "Its Physiology".

Friday, November 12

Biochemical Society (in the Department of Biochemistry, St. Bartholomew's Medical College, Charterhouse Square, London, E.C.1), at 2 p.m.—Scientific Papers.

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

North East Coast Institution of Engineers and Shipbuilders (in the Lecture Theatre of the Mining Institute, Neville Hall, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. B. J. Terrell: "Instrumentation in Engineering Research with Particular Reference to Marine Turbine Machinery".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Kenneth M. Smith, F.R.S.: "What is a Virus?"

Saturday, November 13

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Prof. F. E. Zeuner: "The Camel and the Elephant".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with the National Diploma in Agricultural Engineering or equivalent qualifications, and with a special knowledge of agricultural engineering together with sound practical experience) in Farm Mechanization—The Clerk to the Governors, Essex Institute of Agriculture, Writtle, Chelmsford, Essex (November 10).

Assistant Lecturer or Lecturer in the Department of Inorganic and Physical Chemistry—The Registrar, The University, Liverpool (November 13).

Assistant Lecturers (with special qualifications in physical chemistry) in Chemistry—The Registrar, The University, Manchester 13 (November 13).

Assistant (with a recognized qualification in mathematics or statistics) in the Statistics Section—The Secretary, Long Ashton Research Station, Long Ashton, Bristol (November 13).

Lecturer (with a first- or second-class honours degree in metallurgy or equivalent qualifications, and preferably with practical experience) in the Department of Chemistry and Metallurgy—The Director of Studies, Royal Naval College, Greenwich, London, S.E.10 (November 13).

Lecturer (Grade II) in Agricultural Botany, and an Assistant Lecturer in Animal Husbandry, at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (November 15).

Senior Lecturer in Civil Engineering, Senior Lecturer in Electrical Engineering, and a Lecturer (Grade A) in Electrical Engineering (Radio and Telecommunications), at Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (November 15)

Lecturer (with an honours degree in zoology or agricultural zoology, and with postgraduate experience in one of the following fields: (*a*) mammalian physiology, (*b*) entomology or (*c*) parasites of plants and animals) in Agricultural Zoology; and a Lecturer (with an honours degree in chemistry, agricultural chemistry or zoology, and with postgraduate experience in some aspect of soil research, preferably in soil classification or soil physics) in Pedology—The Registrar, King's College (University of Durham), Newcastle-upon-Tyne (November 20).

Scientific Officers (with a first- or second-class honours degree in engineering, physics or mathematics or equivalent qualification) in the Mechanical Engineering Research Laboratory, Department of Scientific and Industrial Research, East Kilbride, near Glasgow, for research into the following branches of mechanical engineering: properties of materials in the elastic and plastic ranges; fluid mechanics; heat transfer; lubrication; improvement of mechanisms—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.551/54A (November 20).

Lecturer in the Fluid Motion Laboratory, to work on problems of electronics and instrumentation for the measurement and observation of fluid flow, including turbulence, the propagation of shock waves and aerodynamic noise—The Registrar, The University, Manchester 13 (November 27).

Assistant Lecturer or Lecturer in Clinical Psychology—The Registrar, The University, Leeds 2 (November 29).

Professor of Physics at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 1).

Soils Chemist (with a first- or second-class honours degree and at least three years postgraduate experience, and preferably with some experience of tropical soils), at the Rubber Research Institute of Malaya, Kuala Lumpur, to undertake work on soil fertility problems with particular reference to rubber cultivation—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, London, S.W.7 (December 1)

Chief of the Division of Fisheries, Commonwealth Scientific and Industrial Research Organization, to be responsible for the research activities of the C.S.I.R.O. in the fields of oceanography and marine biology, and on scientific problems relating directly to various branches of the fishing industry in Australia—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 320/81 (December 15).

Lecturer (preferably with an interest and experience in vacuum techniques) in the Department of Electronics—The Secretary and Registrar, The University, Southampton (January 1).

Bacteriologist, for sterility testing and supervision of sterile work—The Secretary, Blood Products Laboratory, Lister Institute of Preventive Medicine, Elstree, Herts.

BRITISH RAYON RESEARCH ASSOCIATION RESEARCH SCHOLAR (with a first- or top second-class honours degree in physics or physical chemistry), to work in the Department of Textile Chemistry on rheological problems connected with the interaction of water with assemblages of hygroscopic fibres—The Registrar, College of Technology, Manchester 1.

GRADUATE (preferably with some knowledge of electrical engineering) for work concerned with experimentation and re-design of control points in steelworks to fit the human operator—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "Control".

LIBRARIAN (with a science degree and a working knowledge of French and German)—The Director, Research Association of British Flour Millers, Cereals Research Station, Old London Road, St. Albans.

MASTER to teach physics to scholarship level—The Headmaster, Malvern College, Malvern, Worcs.

ORGANIC CHEMISTS (Ph.D. or equivalent experience) to continue research on the degradation of carbohydrates—The Secretary, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester.

PHYSICIST OF ELECTRICAL ENGINEER (with a first- or second-class honours degree or equivalent in physics or electrical engineering and with research experience in physical optics, photoelectricity, photographic processes or electronics) at the Ministry of Supply, London Headquarters, for duties which include the preparation of contract proposals for research and development projects, scrutiny of specifications, supervision of the work and assessment of results—The Ministry of Labour and National Service, Scientific and Technical Register (K), 26 King Street, London, S.W.1, quoting A.291/54A.

PHYSICISTS (with a first- or second-class honours degree) for fundamental research on (*a*) friction, adhesion and abrasion, and (*b*) ionic diffusion in proteins using radar tracer methods—The Wool Industries Research Association, Torridon, Headingley, Leeds 6.

RESEARCH ASSISTANT (preferably with previous experience of either X-ray crystallography or large-scale computing) IN THE DEPARTMENT OF ORGANIC AND STRUCTURAL CHEMISTRY, to be a member of a small group engaged in preparing programmes for, and carrying out, extensive crystallographic calculations on the Manchester University electronic digital computer—Prof. E. G. Cox, Department of Inorganic and Structural Chemistry, The University, Leeds 2.

SENIOR SCIENTIFIC OFFICER or SCIENTIFIC OFFICER (with a first- or second-class honours degree in chemical engineering or in chemistry with a diploma in chemical engineering, or A.M.I.Chem.E. and preferably with two to four years experience in plant development work), for work covering a wide range of chemical plant development and design problems in the radioactive and inorganic fields—The Senior Recruitment Officer, United Kingdom Atomic Energy Authority, Aldermaston, Berkshire, quoting 248/WGB/2.

TECHNICIAN IN THE DEPARTMENT OF PHYSICS—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1.

TECHNICIAN (with previous experience in a biological or chemical laboratory) IN THE DEPARTMENT OF ZOOLOGY—The Registrar, The University, Nottingham.

SCIENTIFIC MANAGEMENT AND SOCIAL FACTORS

IN October 1952, the Anglo-American Council on Productivity appointed a specialist team to investigate the American approach to the improvement of methods of manufacture and the continuous reduction of operating costs. The team, which visited the United States early in 1953, was concerned with the effect of planning, control, budgeting and costing on the improvement of manufacturing methods; with the relation between design and methods of manufacture; with the means used on the factory floor to improve methods; with the effect of administrative arrangements on methods; and with the educational arrangements for training industrial engineers and for giving tuition in industrial engineering to managements and young workers. The report, entitled "Industrial Engineering", which the team has now produced* sets forth a number of recommendations intended to indicate the steps which British industry should take in the interest of productivity, and it also includes a supplementary report on 'industrial engineering' education in the United States.

Although some of the recommendations involve action by government as well as by industry, both the reports are of general interest to the scientist and to the technologist, as will appear from the definition of industrial engineering adopted by the team for the purposes of these reports. Industrial engineering is regarded as the application of basic scientific and engineering knowledge and certain analytical techniques to the methods of operating an organization in industry and other appropriate fields. It requires investigation into the economic advantages of one policy as against another and implementation of the most suitable procedure for raising productive efficiency. To this end performance and costs need to be checked constantly. Industrial engineering, the report continues, is a staff activity of management, and is concerned with decisions on what to produce, the design of the product, standardization, the influence of cost analysis on methods of production, the investigation of these methods, planning and control of production, calculation of what is the most efficient machinery for the job, layout of plant and handling of materials, design of tools, maintenance of plant, time study, motion study, incentives, method of calculation of wages, suggestion schemes and industrial relations. It requires consideration to be given to the communication of new ideas among senior and junior managers, among supervisors, and to and from workers on the shop floor. It also requires careful regard to the well-being, attitudes and opinions of workers.

The definition is given at length, not so much because the team seriously recommends that the British Standards Institution should set up a committee to deal with the terminology of the whole field of industrial engineering, as because it illustrates the way in which the team has adopted the term to cover activities which are inherent in industrial administration or scientific management, as conceived by such writers as Taylor, Fayol, Urwick, Mayo and Whitehead. It is at least arguable whether it is wise on the grounds of its mechanical connotations alone to use such a term as 'engineering' to cover activities which depend particularly on human co-operation. That alone could be a hindrance to much that is already being done in the field of human relations in industry by the Science and Industry Committee reconstituted early this year. Samuel Butler's "Erewhon" could still be a salutary warning to those who use the words 'machine' or 'machinery' for organization without due forethought.

---

* British Productivity Council. Industrial Engineering—Report of a visit to the U.S.A. in 1953 of a British Specialist Team on Industrial Engineering. Pp. xii+116. (London: British Productivity Council, 1954.) 5s.

At the outset, the report emphasizes the bearing of the social and industrial background on the approach to problems of productivity, and its opening chapter sketches with considerable skill the features of the American background which are significant in this connexion, and more especially those which are also to be found in Britain. Nevertheless, this recognition of the importance of the climate of opinion does not lead the team to examine the means by which that climate of opinion may be made more favourable to the improvement of productivity. Accordingly, recommendations which may be unexceptionable in themselves are made with little appreciation of the magnitude of the repercussions involved. The correct objective may indeed be indicated, but the means recommended sometimes suggest a degree of naïvety or even arrogance that, to say the least, is disturbing.

For example, in stressing the importance of shift work in order that expensive machinery may be used economically, the team rightly recognizes that it is desirable that retail shops and restaurants should be open for the workers coming off duty. When it goes on to suggest legal sanction for such arrangements, it shows little conception of what is thereby involved. Alternative means depending on individual enterprise and initiative are more likely to provide what is required. For the rest, patient but determined education of public opinion and, at the most, no more legal action than is required to prevent restraints contrary to the public interest are the more hopeful lines of advance. It may be surmized that the presence of any investigator from the National Institute of Industrial Psychology among the members of the team would have prevented any such mistake.

So, too, the team's study of industrial engineering education in the United States does not prevent it from making a similarly naïve recommendation that "industrial engineering studies in universities and technical colleges, whether as single subjects or as courses, should be expanded". It is assumed without question that industrial engineering studies are appropriate, both for universities and for technical colleges, and although the report notes that more than half those who enter the courses in American universities fail to complete them, the wastage is accepted without criticism. Whether these four-year courses of industrial engineering with their high concentration on subjects concerned with the application of knowledge rather than basic science are appropriate in a university is not discussed, nor is there any comment on the proposals to replace such four-year courses by less crowded five-year courses.

The team recognizes indeed, so far as Great Britain is concerned, the danger of over-hasty development of 'industrial engineering' studies in the universities, and it makes clear that it is not asking for any change of standards. In fact, although in the United States, out of 127,550 engineering students in 1951–52 there were estimated to be 5,067 industrial engineering students attending sixty schools, while there were thirty-one accredited courses as well as thirteen in mechanical engineering carrying accredited industrial engineering options, the team seems to look to development in the technical colleges rather than in the universities in Britain. It recommends that technical colleges should offer more single specialist courses in such subjects where industry is willing to support them, and that technical colleges should develop further short courses to serve the needs of small businesses. It also looks to the development of the sandwich diploma courses which are being tried in some technical colleges, and to the co-operation of industry in such courses and in the release of employees for part-time day attendance.

The team recognizes the value of participation by the technical colleges in research in the fields covered by its definition of industrial engineering, but the suggestion for courses in industrial engineering is of dubious value. The promotion of contacts between teachers and industry, the encouragement of research and interchange of staff both between Britain and the United States and between Britain and the Continent of Europe are much more likely to be fruitful and assist the expansion which the team recommends.

As has been indicated, a main weakness of the discussion of the educational aspect of the subject in this report is the absence of any clear conception of the functions of a university and of the relative position of university and technical college in regard to technical and vocational training. With that goes a complete indifference to the importance of educating public opinion on the need for new attitudes to shift-work, to motion study and time study, incentives, redundancy and the like. Even in regard to safety, there is nothing more specific than the recommendation that much more education is required on this subject in factories.

By and large, the recommendations of this report endorse many of the projects which have already been taken up by the Science and Industry Committee, and the findings of a number of investigations already completed, such as those of J. F. Scott and B. P. Lynton for the British Institute of Management and of Dr. W. H. Scott of the Department of Social Science in the University of Liverpool. As regards fiscal matters, however, on which the Advisory Council for Scientific Policy hesitated in its report last year, the team is entirely uninhibited. It recommends that the annual depreciation allowance should be revised to facilitate the more rapid writing-down of machinery and equipment. It condemns the effects of present taxation on business and suggests that a more liberal import licensing policy should be adopted to encourage firms to obtain new equipment essential for increasing productivity but not available in Great Britain. It also recommends that the facilities available to small firms for obtaining finance for capital investment should be more widely publicized and used, and that trade and trade associations, including the trade unions, should be legally required, where they do not already do so, to publish any rules or agreements which bind their members.

Such recommendations obviously bear on the utilization of the results of research and the encouragement of research itself, and though one would not have expected to find reference to that aspect of increased productivity in a report under this title, there are in fact references to the need for further effort to encourage the rapid application of the results of research and to the assistance which more efficient services for the dissemination of technical information could give. An appendix on research in the United States quotes an estimate of 2,000 million dollars expended on research by Federal government agencies in 1952–53, of which 94 per cent was spent on applied research. Two-thirds of the United States expenditure on research and development was for work undertaken by private industry, and such industrial research is dominated by not more than twenty firms, each with research staffs of a thousand or more. Some 3,391 engineers and scientists are employed on research by professional industrial consultants, and more than sixty-five per cent of the 44 million dollars expended on such research comes from the Federal government.

The team noted that the American manufacturer employs consultants more freely than the British manufacturer to advise on the development of new products, changes in range of manufacture and the substitution of new raw materials for old. Specifically it recommends that British firms should make greater use of such consultants and also of the practice termed management audit, entailing a check on the effectiveness of senior management by means of an investigation into the operational efficiency of an organization. Such practices, however, presuppose that the main difficulty in the utilization of existing scientific and technical knowledge, emphasized both in the survey "Industry and Research" made by the Manchester Joint Research Council and by Vera Connell more recently in "The Application of the Results of Research", is the lack of at least one person in the confidence of the management who is competent to appreciate the significance for the firm of new knowledge. If in fact there were the receptivity to new ideas and the readiness to exchange ideas which the team notes as characteristic of American business, that part of the problem of increasing productivity would largely be solved.

We thus come back to the fundamental question of the climate of opinion and of how best we are to promote at all levels—not merely at the top—the outlook and readiness of mind favourable to increased productivity and the modification of processes, practices, ideas and attitudes involved thereby. The team obviously appreciates that close contact between industry and the technical Press is important, but in commending the activities and influence of such journals in the United States in this connexion, it seems scarcely aware of the possibilities in Britain. In this respect the report shows the same lack of imagination as characterizes its treatment of education for management, at the university or at the technical college.

It is refreshing to contrast with this report Prof. A. N. Whitehead's characterization many years ago of the needs of a business organization in discussing technical education in his lectures on "The Aims of Education". Prof. Whitehead pointed out even then that those directing a business organization require an imaginative grasp of the psychologies of populations living under a wide range of conditions, of the complexities of interlocking interests involved in its activities, an imaginative understanding of the social effects of conditions in factories, of the laws of political economy and habits of government, some vision of the binding forces of human organization and some knowledge of the laws of health and fatigue; and, above all, the discipline of character which enables management to take and stand by decisions. Prof. Whitehead rejected then, as forthrightly as Dr. R. M. Hutchins and Sir Hector Hetherington have done in our day, the idea that the university is primarily concerned with the technical or professional knowledge which its students may require for an industrial or other career. A university, he insisted, is an institution uniting young and old in the imaginative consideration of learning: it functions in the preparation for an intellectual career by promoting the imaginative consideration of the general principles underlying that career.

In its report for the quinquennium 1929–34, the University Grants Committee unequivocably affirmed that conception of the functions of the university. Had it been remembered by the productivity team on industrial engineering, some of the recommendations of its report might never have been formulated. We might not indeed have received an adequate discussion of the respective functions of the university and of the technical colleges in training for management and specific recommendations; but the human issues involved would at least have been treated more imaginatively and with less risk of the psychological difficulties into which any discussion of human beings and organization in mechanical terms is liable to run. The over-riding emphasis would have been put in the right place. It is not a new name for management and its myriad activities that is required. The first need is to secure by all possible means the change in opinion in industry at all levels, in parliament, and in the country generally which is necessary for management to get on, without obstruction, with its task of raising the general level of productivity in small firms, as in large. This requires the more rapid and continuous utilization of existing technical knowledge and of new knowledge as it comes along, with all that is implied thereby, and the discarding of obsolete and restrictive practices and their imaginative replacement by methods which increase output, lower costs and diminish the hazards, monotony and physical strain which the older methods involved. Along with the task of improving the training for management goes the greater task, in which every bit of assistance that the Press, broadcasting, television, adult education and other means can give will be needed, of securing the climate of opinion in industry and in society which will give wise and progressive management a chance to function.

MEN OF CAMBRIDGE

Alumni Cantabrigienses

A Biographical List of all known Students, Graduates and Holders of Office at the University of Cambridge from the Earliest Times to 1900. Compiled by Dr. J. A. Venn. Part 2: From 1752 to 1900. Volume 6: Square–Zupitza. Pp. iv+627. (Cambridge: At the University Press, 1954.) £10 10s. net. Complete set of 10 volumes, 85 guineas net.

THE president of Queens' College, Cambridge, Dr. J. A. Venn, is to be congratulated most heartily on the completion of his stupendous task in preparing for publication and seeing through the press the biographies of some 140,000 members of the University of Cambridge. It has occupied a great part of his time during the past forty-six years, during which he has served in a world war, carried out the duties of a university lecturer, president of a college and vice-chancellor of the University. He has been helped, naturally, by a small staff (for many years one assistant only), by volunteers from individual colleges and last but not least by the financial support and careful, accurate and pleasing workmanship of the University Press. More than six million words were typed and printed in the course of the work—and read over at least twice by the compiler.

It was to Dr. Venn that the idea of this publication was due in the first place. The sources that were used, the names of those who helped and the history of the whole work are given in the prefaces to volumes 1 of the two parts (to 1751 and 1752–1900) of the whole work. We should have liked to see an epilogue at the end of the last volume, in which Dr. Venn could have given an account of his work, looking back over the whole period from 1908 to the present. He gave a taste of the story that he had to tell in his reply to the congratulations of the University conveyed by the Vice-Chancellor at a reception to Dr. and Mrs. Venn organized by the Syndics of the Cambridge University Press on the day of publication of the tenth and last volume.

An analysis of the Fellows of the Royal Society noted in the present volume, more than a hundred in number, shows six presidents (Wollaston, the Duke of Sussex, Stokes, Kelvin, Rayleigh and J. J. Thomson), a predominance of mathematicians, followed by physicists, clerics, public servants, physicians and geologists in that order; among others, a dilettante, a poet (Tennyson) and a banker. Dr. Venn's father, Dr. John Venn, F.R.S., who kept the work going while Dr. Venn was absent on service during the First World War, and who is associated with Dr. Venn in some of the earlier volumes, is one of six generations of the Venn family to graduate in Cambridge. Thomas Young added to his work as a physicist and physician philological skill which enabled him to find the key to the hieroglyphics on the Rosetta Stone. Two hardened Tories were C. P. Yorke, First Lord of the Admiralty, who strongly opposed the abolition of mutilation after execution for treason, and George Whitmore, tutor of St. John's, who addressed his pupils on "a laudable exhibition of justifiable zeal" in breaking the windows of many Dissenters. T. P. Thompson, who at the same time was a midshipman on H.M.S. *Isis* and a Fellow of Queens', had an unusual career: he described his fellowship as "a sort of promotion, which has not often gone along with the rank and dignity of a midshipman". In view of his start, it is not surprising to learn that he was later governor of Sierra Leone, a general in the Army and a Fellow of the Royal Society. Another Fellow, Richard Watson, was simultaneously professor of chemistry and regius professor of divinity, and later held his professorship of divinity along with the bishopric of Llandaff. He was elected to the chair of chemistry, "having never read a syllable on the subject nor seen a single experiment". That may explain why his workshop was afterwards shattered by an explosion; all the same, he is said to have saved the Government £100,000 by advice on the manufacture of gunpowder.

Such notes as the above in the biographies of eminent men may account for Miss Rose Macaulay's description of the "Alumni Cantabrigienses" as a bedside book. The size, weight and small print of the volumes are against such a description, but the biographies do yield many fascinating notes on men in all classes of society. Thus, Thomas Turner, a distinguished physician, was garrotted by ruffians at the age of ninety and was thereby cured of his goitre. John Steggall, who had run away from school and lived with gypsies, came up to Corpus Christi after having been to sea on a whaler and serving in the army in India. He later took Holy Orders and also practised as a surgeon. Edward Tatham preached a famous sermon, 2½ hours long, and left the subject of his discourse to be settled by the learned bench of bishops "who have little to do and do not always do that little"; H. H. Vivian, while an undergraduate, brought to England the first camera to pass the London custom house, and afterwards took a daguerreotype, still extant, of a "Breakfast Party" of undergraduates. William Henry Waddington was later naturalized as a French citizen and became in due course Prime Minister of France. William Yardley made the first century in the University match. Edward Wilson of the Antarctic, who reached the South Pole with Captain Scott in 1912, and A. F. R. Wollaston, surgeon and naturalist to the first Mount Everest expedition in 1921, deserve mention among many distinguished Cambridge explorers.

But these volumes can serve many purposes more valuable than that of interesting the casual reader. Sir A. F. Rook has used them to disprove the common view that early subjection to severe athletic strain shortens men's lives, and Mr. Caradog Jones to pursue various sociological studies. The list of biographies provides a mine of information into which inquirers will delve for generations. It is good to know that the University has set up an organization to preserve its archives and to facilitate the work of Dr. Venn's successor, when the burden which he has now set down is taken up again some fifty years hence.

F. J. M. STRATTON

LIFE AND SENSES OF THE HONEY BEE

The Dancing Bees

An Account of the Life and Senses of the Honey Bee. By Karl von Frisch. (Translated by Dora Ilse.) Pp. xiv+184+30 plates. (London: Methuen and Co., Ltd., 1954.) 16s. net.

KARL VON FRISCH is one of the most distinguished of living experimental zoologists, and it is to him that we are indebted for the greater part of recent advance in knowledge of the behaviour and sense organs of the honey bee. It follows that the publication of a good English translation of the fifth revised edition of "Aus dem Leben der Bienen", a popular and completely up-to-date book by him, is something of an event.

The translation is strictly faithful to the original and has on the whole been admirably done by Dr. Dora Ilse; there are very few places where a slight awkwardness of phrase betrays that it has in fact been put into English by one who is not herself English.

The knowledge of German possessed by most biologists in Great Britain is not by any means so extensive and precise as it should be, and many of us who have perhaps battered an exhausting and uncertain course through the verbose entanglements within which the gems of discovery of the average German biologist are hidden will have come with relief and delight to the scientific papers of von Frisch. Here at last are experiments and results of an unrivalled perfection described with such simple lucidity and logic as to flatter us that our knowledge of the language is, after all, better than we thought. Quite apart from the language itself, what a delight it is to be able to see from the simple narrative style of von Frisch exactly how the investigation developed: to see the extraordinary flashes of insight, the weary plodding after statistical 'certainty'—and no less to be able to appreciate the long treks after false scents and up blind alleys. Nevertheless, if only because several of von Frisch's original papers are by no means easy of access, a great many biologists will welcome the concise simplified account of the beautiful investigations by himself and others, many of them his pupils, which Chapters 7–12 of this book provide. Even the most expert student of bees is likely to profit by reading it, for again and again a descriptive aside or apparently casual observation suggests some new approach to the problems of the evolution of bee organization, or reveals some hitherto unsuspected nicety of adjustment of behaviour to the needs of the colony.

About the rest of the book it is not easy to be quite so enthusiastic. The six introductory chapters are apparently written for readers who are presumed to know nothing at all about either biology in general or bees in particular. There are many gems of precise and vivid description here: thus the honey-stomach is aptly likened to a shopping bag, and a laden pollen collector is described as looking as if she were wearing 'plus fours'. But in spite of such happy phrases the general effect of the extreme simplicity of diction is to give a 'told to the children' air which is somewhat wearisome, and the question is whether a reader who needs this kind of thing will really be able to appreciate the more advanced sections. Although the book has had a great success in Austria and Germany, one wonders if it will meet quite the same need in English-speaking countries, where there are already so many good popular accounts of the natural history of bees and other social insects; and it is against this competition that the book must be judged.

In writing such a popular book it is scarcely possible for an author to avoid all the pitfalls of over-simplification, and the very brilliance of von Frisch's powers of exposition has perhaps led him astray at times. Thus not many zoologists will agree to the description of *Amoeba* as "a little lump of mucus come alive". Again, in describing the star-shaped 'Polaroid' filter as a demonstration of one of the possible ways in which the compound eye could mediate appreciation of the polarization characteristics of light reflected from the blue sky, the author seems in several places to imply that the individual ommatidia must actually be functioning in this way, and he nowhere alludes to the neurological problems which such a theory raises. For if each of the eight sensory cells which go to make up an ommatidium is in fact registering and passing separately to the brain the information it receives, a radical revision of some present concepts as to the mode of action of the sensory fibres will probably be necessary, and many of our present ideas about the compound eye may have to be revised. There are other similar points in the work which might be questioned. But in spite of such, the book is undoubtedly a masterpiece of condensation and simplification by a very great zoologist summarizing a life-time of research—research which has been largely instrumental in initiating a re-appraisal of some of the basic ideas about invertebrate sense organs and behaviour.

Von Frisch is very reticent about theory, and generally prefers that the facts should speak for themselves and that others should do the theorizing. Perhaps it is for this reason that the brief chapter on "Mental Capacity" is somewhat misleading. Here he states that no example of 'really intelligent action' by honey bees has ever been recorded; whereas what he means is that the ability to cope with new problems is strictly limited to certain situations only. Their ability to remember colour, odour and relative position of landmarks is extraordinary, and their powers of combining these memories and associating them with a given passage of time is even more remarkable. Every such combination learnt involves some perception of relations, and when a bee makes a detour around an obstacle and afterwards straightens its path as a result of experience it is showing, within strict limits, an insightful action. Moreover, the author supports his conclusions by citing lack of 'intelligence' in other insects; but to do this he merely quotes a story about a 'mason bee' and fails to cite much striking evidence to the contrary—not only with the mason bees *Eumenes* and *Rhynchium*, but also the far more conclusive and precise experimental studies of adaptive behaviour in the hunting wasps *Philanthus* and *Ammophila*. Indeed, his treatment of social and semi-social insects other than *Aphis mellifica* is too brief to be of much value, and is perhaps the least satisfactory chapter of the book.

But in spite of such shortcomings, it must be said that there are not many scientists of like eminence who could produce such a good popular book. Quite apart from its general educative and instructional value, it will, if it leads biologists as a whole to give more attention to simplicity and clarity in exposition, have a most valuable effect. W. H. THORPE

BLOOD GROUPS

Les groupes sanguins chez les animaux

Individualités sanguine et tissulaire. Par R. Dujarric de la Rivière et A. Eyquem. (Collection de l'Institut Pasteur.) Pp. 407 + 2 plates. (Paris: Éditions Médicales Flammarion, 1953.) 3,275 francs.

BLOOD-GROUP differences between individual goats were described by Ehrlich and Morgenroth in 1900 only a few months after Landsteiner's announcement of his discovery of the human blood groups. Ever since then, research on animal blood groups has continued and an enormous literature has been built up, scattered through very many journals and very varied in its methods and its aims, in contrast to the fairly well-integrated study of the human blood groups. Hitherto, almost the only comprehensive account of the subject has been a single excellent chapter in Wiener's "Blood Groups and Transfusion", so that a book bringing together the scattered threads has long been needed by workers in the field itself and in many related branches of science, especially, for purposes of comparison, by investigators of the human blood groups. That Dr. R. Dujarric de la Rivière and Dr. A. Eyquem have undertaken the task of reading and summarizing this vast literature entitles them to the gratitude of all such workers.

The title, "Les Groupes Sanguins chez les Animaux", as it appears on the outer cover, is supplemented on the title page by the words, "(Individualités sanguine et tissulaire)", and this extension of the subject to cover the whole of tissue immunity has involved the reading of another vast body of literature and has made the area covered so wide that no one or even two authors could possibly treat the whole of it critically.

Blood-group investigations require a knowledge both of serology and of genetics. The authors are primarily serologists, and the book is much sounder in its treatment of serology than of genetics. It is quite impossible for anyone to compress the whole of genetical theory, as the authors have attempted, into eighteen pages in a way that will be useful as an introduction to the genetics of the blood groups. To those without a knowledge of genetics such an account is inadequate; to those with the knowledge it is unnecessary.

Because the human blood groups have been more thoroughly investigated than those of any of the lower animals, an account of them is a necessary part of a book such as this; but it is the weakest part of the present book, containing numerous errors and statements of doubtful validity, especially on the genetical side. There is, for example, no evidence that (p. 64) the red cells of $Lu^a\ Lu^a$ individuals are more strongly agglutinated than those of heterozygotes; and the tabulation of the Lewis genotype $Le^b\ Le^b$ as corresponding to the phenotype $Le\ (a-b-)$ (p. 65) is contrary to the facts.

Most readers will, however, turn at once to chapter 5 on the blood groups of various animal species. It is disappointing to find that this central subject of the book is dealt with in only 90 out of a total of more than 400 pages. Nevertheless, nearly every investigation of any importance is adequately, if not critically, described. Of particular interest are the accounts of antigenic differences between different breeds of certain animals, especially sheep. On the other hand, the more difficult genetical topics are not so well treated, and the profoundly interesting subject of the linkage groups in cattle and some other animals, their similarities to and differences from the human *Rh* system, deserves more space than it is given. There is a very good and comprehensive chapter on hæmolytic disease of the newborn among animals which will greatly interest comparative pathologists.

More than a hundred pages are devoted to the subject of tissue antigens, cytotoxic antibodies, and tissue grafting. The treatment appears on the whole to be adequate, but the reviewer is only familiar with a small part of this extensive field. It is surprising that only about four pages are devoted to a subject of such great practical importance as skin grafting.

A very valuable feature of the book is an alphabetical bibliography of some eight hundred entries. A number of these have been checked—some minor spelling mistakes were found but no errors in dates, volume numbers or pages. The bibliography includes most of the papers of first importance, but a very considerable number of the works cited in the text are not included in the bibliography. Names, other than French, are very frequently misspelt in the text, but are mostly correct in the bibliography. There is a short but adequate general index.

Despite its faults, this book is an indispensable work of reference. It is most unlikely that in the near future anyone else will undertake the task of re-reading this immense literature. It is almost inevitable that in a few years a new edition will be needed. It is suggested that the authors should then omit the section (pp. 35–52) on general genetics, should call into collaboration a geneticist to ensure a more adequate treatment of the genetical and statistical aspects of the blood groups, should include in the bibliography references to all papers mentioned in the text, and should deal more fully with experimental skin grafting.

A. E. MOURANT

ELECTRON MICROSCOPY AS A TEXT-BOOK SUBJECT

Introduction to Electron Microscopy

By Prof. Cecil E. Hall. (International Series in Pure and Applied Physics.) Pp. ix + 451. (London: McGraw-Hill Publishing Company, 1953.) 64s. 6d.

THE final stage in the maturity of a branch of science or technology is the establishment of university lecture courses about it and the reduction of the sprawling, groping literature of its infancy to text-book form. By these standards electron microscopy has now come of age, as indeed the lapse of time since the invention of the first electron microscope would indicate. To gain entry to the McGraw-Hill International Series in Pure and Applied Physics adds the hallmark of respectability to a young and still somewhat revolutionary discipline.

The text now offered by Prof. C. E. Hall is based on his lectures to postgraduate students in biophysics at the Massachusetts Institute of Technology. It may be felt that it is much more detailed in its treatment of physical fundamentals than such a class would either understand readily or be likely to need in practising the subject. But the author has deliberately chosen such an approach, with an eye to probable future developments in the design of the instrument and in its operation. This is undoubtedly the wisest course to follow, although it will make the text long and in parts heavy going for "science and engineering students with a background in physics and engineering at about the sophomore level".

That said, nothing but praise is due to this volume, both for its choice of material and for its presentation. The first two chapters form a résumé of fundamental physical theory, including an outline of wave mechanics, and the motion of electrons in electrostatic fields. The next three chapters discuss the ideal lens and then the practical electrostatic and magnetic lenses, the aberrations of which are dealt with in Chapter 6. The essential features of the electron microscope and its commercial realization are the subjects of Chapters 7 and 8. Chapter 9, one of the most valuable in the book, treats scattering phenomena as a prelude to the discussion of image formation in Chapter 10. The remaining two chapters deal thoroughly with the most important methods of specimen preparation and with typical examples of the applications of the electron microscope.

The text is marked by that clarity which follows from complete familiarity with a subject, and it is illustrated by plenty of excellent diagrams and photographs, remarkable even for this series; at a quick estimate there are some 350 figures, or nearly one per page. Most chapters are followed by problems to test the understanding of the student, and at the end it is a pleasure to find such full author and subject indexes. Although there is room, as in any new subject, for differences of opinion on the presentation of some points, such as the alignment of lenses, the book can be unreservedly recommended to all workers in the field, whether they be students or older practitioners; in fact, it is much more of a handbook than an introduction.

V. E. Cosslett

MAMMALIAN GERM CELLS

Mammalian Germ Cells

Edited by G. E. W. Wolstenholme, assisted by Margaret P. Cameron and Jessie S. Freeman. (A Ciba Foundation Symposium.) Pp. xvi+302+15 plates. (London: J. and A. Churchill, Ltd., 1953.) 30s. net.

This symposium conducted at the Ciba Foundation "for the promotion of international co-operation in medical and chemical research" has assembled thirteen papers concerned with the physiology of spermatozoa and eleven papers concerned with ova. It represents an attempt to bring together in a series of relatively brief presentations recent progress in these rapidly advancing fields. In addition to the formal papers, there is included the discussion of each by the various members of the symposium.

There can be no doubt that the general objective is attained. The various discussions of spermatozoa include analyses of the biochemistry of semen. In a number of instances attempts are made to correlate certain biochemical properties with practical problems in reproduction. For example, there is a critical review of aerobic metabolism in semen and its relationship to fertility in a paper by Dr. C. Terner. Again, Mr. J. C. N. Kok discusses the factors influencing the longevity of bull semen as used for artificial insemination. Of more interest to the physiologist and biochemist are the papers on the biochemical aspects of semen (by Dr. T. Mann), on factors controlling metabolic rates of mammalian spermatozoa (by Dr. H. A. Lardy) and on proteolytic enzymes in human semen (by Dr. F. Lundquist). A fascinating discussion on the movements of spermatozoa by Lord Rothschild reveals hitherto unsuspected hydromechanical relationships. The recent work on the preservation of spermatozoa at extremely low temperatures is informatively presented by Mr. C. Polge. The implications of this low-temperature work for the general problems of mammalian fertility and the preservation of desirable genetic characteristics are most fascinating. The practical implications of spermatozoology in human health and disease are ably presented by Dr. J. MacLeod.

Investigations of mammalian ova described in this volume are concerned with: (*a*) ovulation, (*b*) ovum maturation, (*c*) ovum transplantation, (*d*) *in vitro* studies with mammalian eggs, (*e*) early developmental physiology, and (*f*) medical problems relating chiefly to the ovum and pregnancy. As in the case of the spermatozoa, the problem of the longevity of the mammalian egg is touched upon in practically every phase of these investigations. This is especially apparent in the paper by Dr. S. A. Asdell on the effect of controlled ovulation upon the fertility of the mammalian egg, the paper by Dr. M. C. Chang on the fertilizability of rabbit germ cells and a paper by Dr. L. E. Casida on factors affecting fertilization and embryonic death. One of the chief mysteries relating to the development of the mammalian ovum is the problem of fertilization *in vitro*. This is discussed particularly in the paper by Mr. O. Venge, but forms part of the discussion of a number of the papers. The great difficulty experienced by a number of investigators in consistently effecting fertilization *in vitro* is emphasized. The experiments of Audrey U. Smith on the effects of low temperature on rabbit eggs signalize another field of experimentation which parallels similar work with spermatozoa. The transplantation of ova subjected to various experimental conditions is ably reviewed by Mr. C. E. Adams as well as by Dr. Chang. The clinical aspects are presented in papers by Dr. P. N. F. Bishop and Dr. Ian Donald.

It is, of course, not possible to present criticism of the numerous experimental details contained in this assemblage of papers. I find the presentation of sperm biochemistry comprehensive and adequate. The biochemistry of the egg is much less well established. For example, the knowledge of enzymatic transformations and the carbohydrate metabolism of sperm has no counterpart in ovum investigations. This may be due in part to the need for the development of adequate micro methods for use with the limited number of ova available for study. There is only tangential discussion of the role of hormones as regulators of sperm and ovum physiology. Although it is clear that some of the effects of the gonadal hormones may be indirect, nevertheless it would have been useful to have set forth their function in creating specific environments for spermatogenesis, ovulation, fertilization and early development.

There can be no question of the great usefulness of this volume to active investigators in the field of mammalian germ cells. It should be of fundamental interest also to persons interested in the problems basic to modern animal husbandry. Although in no sense a book for the medical practitioner, the thoughtful physician interested in problems of fertility and sterility should find this symposium informative and stimulating.

Gregory Pincus

Geometrical Mechanics and de Broglie Waves

By Prof. J. L. Synge. (Cambridge Monographs on Mechanics and Applied Mathematics.) Pp. vii+167. (Cambridge: At the University Press, 1954.) 25*s*. net.

GEOMETRICAL optics as well as Newtonian mechanics are based on the same variational principle $\delta \int v ds = 0$. In one case, v is the medium function; in the other, it is the velocity. Geometrical optics deals with rays and associated wave-surfaces. The same ray–wave relationship must, therefore, also be available for Newtonian mechanics. Starting with this important observation, Prof. J. L. Synge builds up the theory of "relativistic geometrical mechanics", in analogy with Hamilton's geometrical optics. Sources of light are replaced by space–time events, radiating world lines into the future; the wave-surfaces are three-dimensional surfaces in space–time—in fact, de Broglie waves, moving with a velocity which can be calculated from that of the associated ray.

If the concepts of wave-length, secondary waves, etc., are added semi-intuitively to the structure of geometrical optics, the resulting scheme (physical optics) suffices to give an adequate description of most optical phenomena. It provides easy solutions of problems where Maxwell's theory of electromagnetic waves would be difficult to apply. By analogy, Prof. Synge argues that a "primitive quantisation" of the scheme of relativistic geometrical mechanics (introduced by postulating that adjacent three-waves of equal phase are separated by a quantum of action h) would stand in the same relation to Schrödinger's wave mechanics as physical optics does to Maxwell's theory. A number of special cases are then discussed, among them the case of a particle in an electromagnetic field, and the case of the hydrogen atom.

Although one may wonder if Prof. Synge has not exhausted the possibilities of obtaining exact solutions, the novelty of his point of view is attractive and refreshing. The difficulty of the monograph comes from the relative unfamiliarity of the optical method of Hamilton, which had to be used, and the rather unfamiliar terminology. However, the effort of learning the new point of view is indeed very rewarding.

ABDUS SALAM

Three Abietaceous Cones from the Wealden of Belgium

(Mémoire No. 125 de l'Institut Royal des Sciences Naturelles de Belgique.) Par K. L. Alvin. Pp. 42+5 plates. (Bruxelles: Institut Royal des Sciences Naturelles de Belgique, 1953.)

IN this sumptuous monograph, a beginning is made to the detailed description and classification of some of the remarkably well-preserved fossil plants in the collections of the late Prof. C. Bommer, from Wealden clays in the Hainaut district of Belgium. The plants are preserved as a kind of lignite, in clay, and they have yielded to examination by microtome sections prepared by softening the material and then embedding in celloidin. In the cones here described, it has thus been possible to make a critical study of anatomical features, including the vascularization of the seed scales.

The three species of cones identified illustrate the importance and diversification attained by the family of the Abietaceae at this critical horizon in early Cretaceous times. The author reserves judgment on generic affinity and uses the form genus *Pityostrobus* Nathorst for all of them, having regard to the absence of information on associated vegetative characters. It has been possible, however, to define the species on a range of characters which is unusually wide for fossilized conifers. *P. andraei* (Coemans), a widely-spread species, and *P. bommeri* Alvin probably both represent extinct species of the genus *Pinus*; while *P. corneti* (Coemans), which is taxonomically perhaps the most interesting of the three, shares some characters with *Cedrus* and some with *Keteleeria*, and no doubt represents an extinct genus.

The continuation of such detailed studies of Cretaceous and of younger members of the Abietaceae should do much to elucidate the later evolution of this highly successful family, and thus add to the remarkable history of the Coniferales which has been placed on so well documented a basis by the work of Florin on the earlier members.

Organic Syntheses

An Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. Edited by Charles C. Price. Vol. 33, 1953. Pp. vi+115. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 28*s*. net.

THIS issue maintains the reputation of the series by recording reliable practical details for a further selection of forty compounds, of varied nature and interest. Among them, creosol (2-methoxy-*p*-cresol) is obtained by treating an ethanolic solution of vanillin with amalgamated zinc and concentrated hydrochloric acid, the aldehyde group being reduced to methyl; dimethylketene distils over in 50 per cent yield as a solution in ethyl acetate when α-bromo*iso*butyryl bromide is added dropwise to boiling ethyl acetate and zinc turnings in an atmosphere of pure dry nitrogen under a pressure of 300 mm. mercury; and 9-fluorenecarboxylic acid results almost quantitatively when benzilic acid is stirred with pure benzene and anhydrous aluminium chloride. Other preparations include nicotinonitrile from nicotinamide; α-phenylcinnamic acid, and pure *cis*-stilbene therefrom; pyridine-N-oxide from pyridine and 40 per cent peracetic acid; and stearone from stearic acid. The cumulative index covers Vols. 30–33 of the series. An inserted leaflet directs attention to the explosive nature of the sodium salt of nitromalonaldehyde, mentioned in Vol. 32.

JOHN READ

The Year's Work in Librarianship

Volume 17, 1950. Edited for the Library Association by W. A. Munford. Pp. x+270. (London: Library Association, 1954.) 40*s*.

THIS is the last of a series of seventeen volumes, for it is considered that *Library Science Abstracts*, together with the projected "Five Years' Work in Librarianship", the first volume of which will cover the period 1951–55, will better meet the needs of librarians. Besides the usual book list, this final volume includes chapters on national and university libraries by A. C. Townsend, special libraries (B. C. Vickery), library co-operation (C. C. Adams), library buildings (E. F. Patterson), library practice (G. R. Davies, M. Piggott and W. C. Berwick Sayers), and subject bibliography (P. D. Record). As usual, the volume is well produced, and though the claim is justified that present needs will be better met in other ways, some will nevertheless regret the displacement of a convenient reference work which has proved its value.

THE PROBLEM OF THE TWO TYPES OF DIAMOND

By PROF. G. B. B. M. SUTHERLAND, F.R.S., D. E. BLACKWELL* and W. G. SIMERAL†

Randall Physics Laboratory, University of Michigan, Ann Arbor

Introduction

EXACTLY twenty years ago, Robertson, Fox and Martin[1] reported the existence of two types of diamond having marked differences in infra-red and ultra-violet absorption, in photoconductivity and in birefringence. Somewhat later, Raman and Nikalantan[2] reported that many diamonds had extra spots or streaks in their X-ray diffraction patterns. This observation was confirmed by Lonsdale and Smith[3], who reported that extra streaks were characteristic of type I diamonds and also that in general type II diamonds appear to be much more mosaic in structure than type I diamonds. The principal characteristics of the two types of diamond as determined from these early investigations are summarized in Table 1.

Table 1. CHARACTERISTIC FEATURES OF THE TWO TYPES OF DIAMOND

Physical property	Type I	Type II
Infra-red absorption	Bands at 4–5 μ Absorption 8–10 μ	Bands at 4–5 μ None between 8 and 10 μ
Ultra-violet absorption	Complete beyond 3000 A.	Transparent to 2250 A.
X-ray diffraction	Shows extra spots and streaks	Normal
Photo-conductivity	Poor	Good
Birefringence	Present	Absent

Afterwards, Sutherland and Willis[4] and also Ramanathan[5] showed that type I diamonds are not uniform in their infra-red absorption, since the extinction coefficient of the 8–10 μ band varies very widely from diamond to diamond. Thus the type II diamond may be regarded as a limiting case in which the value of the extinction coefficient of the 8–10 μ band has become vanishingly small. A similar gradation has been found in the position of the ultra-violet cut-off and in the intensity of the extra spots in the X-ray diffraction patterns. Thus, diamonds may be more satisfactorily classed as extreme type I, medium type I, weak type I and type II. It should be added that Blackwell and Sutherland[6] have reported two types of type II diamond neither of which exhibited any absorption in the 8–10 μ region but which showed differences in the 3–5 μ region.

No explanation for these anomalies in the physical properties of diamonds has yet been put forward which has received general acceptance. In an attempt to seek a satisfactory solution of this puzzling phenomenon, we have made an extensive investigation of the infra-red and ultra-violet spectra of a selection of diamonds. In a short paper giving an account of some of the early results[6], we suggested that the type II diamond was a normal pure diamond, whereas all type I diamonds had some impurity or imperfection in their structure which would account for the anomalies. The purpose of the present article is to present briefly the main results of our investigations with particular reference to the imperfection theory.

Type I and Type II Diamonds

First, however, it is necessary to consider a little more carefully the distinguishing features of type I and type II diamonds. Although any one of the properties listed in Table 1 has been generally accepted as a reliable guide in distinguishing type II from type I diamonds, the parallelism of all the physical properties is not at all satisfactory in classifying type I as 'extreme', 'medium', or 'weak', and occasionally a diamond classed as type II on the basis of one physical property would be classified as type I if one of the other properties were used. In a paper primarily concerned with possible correlations between the counting properties of diamonds and their crystal texture (as shown by divergent beam X-ray photographs) Grenville-Wells[7] has listed various physical properties of thirty-eight diamonds. Four of these diamonds had a cut-off in the ultra-violet below 2400 A., yet exhibited anomalous extra-strong X-ray streaks; thus by ultra-violet examination these four diamonds would have been classed as weak type I, but by X-ray streaks as medium or strong type I. Similarly, three diamonds which showed no extra streaks (and would therefore have been classified as type II) had their ultra-violet cut-off at wave-lengths longer than 2830 A. (indicating that they were medium or strong type I). Through the courtesy of Dr. Grenville-Wells, we have been able to examine the infra-red spectra of thirteen of these thirty-eight diamonds. We have found that in every case there is excellent correlation between the infra-red and ultra-violet method of classifying diamonds, but very poor correlation between the infra-red and X-ray method. In this connexion it should also be added that the observations of Grenville-Wells have shown that mosaic character cannot be reliably correlated with type II diamonds as originally suggested by Lonsdale[3].

There is therefore strong evidence that the same cause operates in producing the extra absorption found in the infra-red and ultra-violet spectra of all type I diamonds, but that additional factors may be the cause of the extra streaks and of the mosaic character found in the X-ray photographs of certain diamonds. In view of this, we propose to use a modified nomenclature in the future for the description of type I and type II diamonds. A diamond which is found to be type I (or type II) by spectroscopic means will be denoted by I*S* (or II*S*), whereas a diamond classified by X-ray methods will be denoted by I*X* (or II*X*). The spectroscopic symbol can be elaborated to read *Sir* or *Suv*, depending on whether infra-red or ultra-violet radiation was used in making the classification; similarly, the X-ray symbol should be modified to read *Xl* or *Xd* to indicate whether the diamond was classified by extra streaks on a Laue photograph or mosaic character as shown by a divergent-beam technique. Possible extensions of this notation by using combinations of the *S* and *X* symbols together with *s*, *m* and *w* to denote extreme, medium and weak are sufficiently obvious and need not be discussed here.

---

* Now at the Solar Physics Observatory, University of Cambridge.

† Now with E. I. duPont de Nemours Co., Wilmington, Delaware.

The distinctions just drawn between the various type I and type II diamonds are important in what follows, because in this communication we shall restrict our discussion to *IS* and *IIS* diamonds. It appears to us that at least some of the confusion in the diamond problem can be eliminated in this way. In other words, there are several type I and type II diamond problems and we propose to start with the *IS* and *IIS* types, since the classification by infra-red and ultra-violet absorption has been found (by the examination of several hundred stones) to give very consistent results.

We may begin by considering what would be predicted for the ultra-violet and infra-red spectra of diamond, assuming the Bragg structure and the current theories of molecular spectra.

Ultra-violet Absorption of an Ideal Diamond

From the examination of the ultra-violet spectra of large numbers of hydrocarbons, it has been found that only those hydrocarbons which contain a double or triple carbon–carbon bond exhibit absorption at wave-lengths longer than 2000 A. Since diamond presumably contains only single bonds, its ultra-violet cut-off might be expected to be below 2000 A. Since no *IIS* diamonds have been found with a cut-off below 2200 A., it appears at first sight as if all diamonds are anomalous in their ultra-violet absorption, with *IIS* less anomalous than *IS*. However, Klevens and Platt[8] in an investigation of the ultra-violet spectra of branched saturated hydrocarbons have shown that, as the degree of branching increases, the edge of the ultra-violet cut-off moves to longer wave-lengths; for example, from 1715 A. in *n*-pentane, to 1795 A. in 2,2,3,3-tetramethylpentane. One might, therefore, anticipate that diamond (which from this point of view resembles an extremely highly branched large hydrocarbon molecule) would have its ultra-violet cut-off in the neighbourhood of 2000 A. In order to test this hypothesis, we have examined the ultra-violet spectrum of adamantane ($C_{10}H_{16}$), which consists of four 'fused' *cyclo*hexane rings and which would yield diamond if it ever could be 'polymerized'. The ultra-violet cut-off of adamantane, while not as sharp as that of a *IIS* diamond, is indeed very close to 2200 A. We should add that Herman[9] has recently made a theoretical calculation of the separation between the filled and unfilled electronic energy-levels of diamond and obtained a value of approximately 6 eV. This corresponds to an absorption edge of about 2050 A. We therefore conclude that the *IIS* diamonds have perfectly normal ultra-violet absorption and that only the *IS* diamonds are anomalous.

Infra-red Absorption of an Ideal Diamond

From investigations on the infra-red absorption spectra of hydrocarbons, the force constants involving carbon–carbon bonds are sufficiently accurately known to make it certain that the fundamental frequency spectrum of the diamond lattice must extend from about 1,400 cm.$^{-1}$ (7·1 μ) to about 300 cm.$^{-1}$ (33 μ). The exact distribution of the normal modes over this range is a much more difficult problem, but calculations have been made by Smith[10] which give reasonable agreement with the observed second-order Raman spectrum, and her results can be regarded as a very good first approximation to the true distribution. It is necessary to consider next to what extent these frequencies may be expected to be active in absorption. Using the results of Teller[11] and Lifshitz[12], it can be shown that none of the fundamental frequencies should be active in absorption, but that combinations of fundamentals may give rise to absorption.

Now *IIS* diamonds exhibit no absorption between 1,800 cm.$^{-1}$ and 100 cm.$^{-1}$ (that is, the fundamental region), but do have bands between 3,500 cm.$^{-1}$ and 1,800 cm.$^{-1}$ (that is, the region of combination frequencies). Thus *IIS* diamonds are completely normal in their infra-red as well as their ultra-violet absorption.

Problem of the IS Diamonds

The conclusion that *IIS* diamonds are perfectly normal in their optical absorption properties is an important one. The problem of the *IS* and *IIS* types of diamond is now reduced to the problem of why *IS* diamonds show anomalous absorption. A few years ago, two of us suggested[6] that the extra absorption found in *IS* diamonds might be due to impurity centres in diamond. The exact nature of these was not specified. Impurity centres may consist of (1) foreign atoms, (2) missing carbon atoms, or (3) carbon atoms which are not in the same electronic state as the majority of carbon atoms in the diamond lattice. We may now consider what the effects of such impurity centres would be on the absorption spectrum of diamond.

(*a*) *Ultra-violet spectrum*. It is now well established that chemical impurities in silicon and germanium cause the edge of the main absorption band in these elements to move to longer wave-lengths[13]. Thus the shift of the absorption edge from 2250 A. in *IIS* diamonds to 3000 A. (or even farther) in *IS* diamonds could be due to chemical impurities. The effect of missing carbon atoms on the ultra-violet spectrum is not so easy to predict; but, in general, lattice defects of this type may be expected to decrease the gap between the ground state and the lower edge of the first band of energy-levels. Thus the observations are probably also consistent with this second type of impurity centre. The third type of impurity centre might also be expected to cause a shift of the absorption edge to longer wave-lengths, but in addition might be expected to give rise to discrete lines superimposed on the continuous absorption. Such discrete lines are observed, and we have been able to prove that certain of these lines are closely correlated with certain infra-red absorption bands in the range below 1,800 cm.$^{-1}$ (cf. (2) below).

We may conclude that the extra absorption shown by *IS* diamonds in the ultra-violet can be readily accounted for in a qualitative manner by an impurity theory and that, of the three types of impurity centre considered, that arising from carbon atoms in an abnormal state seems the most probable.

(*b*) *Infra-red spectrum*. Anything which destroys the centre of symmetry midway between each neighbouring pair of carbon atoms in the ideal diamond lattice can cause absorption to occur in the region of fundamental frequencies. Thus any of the three varieties of impurity centre considered could conceivably account for absorption by *IS* diamonds in the region below 1,800 cm.$^{-1}$. Before discussing which seems most probable, we shall summarize the most important results of our investigations on the infra-red spectra of *LS* diamonds.

(1) Absorption maxima of variable intensity have been found in *LS* diamonds at the following frequencies below 1,800 cm.$^{-1}$: 1,540, 1,520, 1,426, 1,372, 1,332, 1,282, 1,203, 1,171, 1,093, 1,003, 780, 480 and 328 cm.$^{-1}$. No absorption was found between 300 cm.$^{-1}$ and 100 cm.$^{-1}$. All but two of these bands appear to fall into two groups (as shown in Table 2) in the sense that the bands in each group always occur together and have the same relative intensity, but there is no correlation between the bands in the separate groups. The two maxima near 1,530 cm.$^{-1}$ have not so far been correlated with either group; but this may be due to the difficulty of making accurate intensity measurements on these weak bands. Many of the group *B* bands (for example, at 1,426, 1,372, 1,332 and 328 cm.$^{-1}$) are very sharp. All the group *A* bands are broad.

Table 2. DISTRIBUTION OF THE ABSORPTION BANDS OF *LS* DIAMONDS

Group *A* (cm $^{-1}$)	Group *B* (cm.$^{-1}$)
1,282	1,426
1,203	1,372
1,093	1,332
480	1,171
	1,003
	780
	328

(2) It has been found that as the intensity of the group *A* bands increases, the cut-off wave-length in the ultra-violet moves to longer wave-lengths and the intensity of an ultra-violet line at 3157 A. increases. However, in *LS* diamonds containing group *B* bands, the intensity of this group of bands is independent of the position of the ultra-violet cut-off, but is correlated with the intensity of an ultra-violet absorption line at 4155 A.

(3) Following the methods of Smith[13], we have calculated the branches of the vibration spectrum of the diamond lattice and have been able to explain the high frequency ($>$ 1,800 cm.$^{-1}$) bands of *LS* and *IIS* diamonds in terms of allowed combinations. The group *A* bands in the low-frequency ($<$ 1,800 cm.$^{-1}$) spectrum of *LS* diamonds can also be accounted for in this way; but most of the group *B* bands cannot be associated with calculated maxima for the ideal diamond lattice.

(4) When *LS* diamonds are heated to 400° C., the only detectable change in the infra-red spectrum (between 4,000 and 700 cm.$^{-1}$) is a decrease of about 30 per cent in the intensity of the 1,372 cm.$^{-1}$ band. This band also moves to lower frequencies as the temperature increases, the temperature coefficient being 1 cm.$^{-1}$/50° C. Diamonds (*LS* and *IIS*), which had been heated to 1,700° C. and were re-examined at room temperature, showed no change in infra-red spectrum.

(5) The infra-red absorption bands of *LS* diamonds show no dichroic effects in regions where optical birefringence is observed.

(6) Irradiation of *IIS* diamonds by neutrons, deuterons and γ-rays has so far failed entirely to produce any of the absorption bands characteristic of *LS* diamonds. Neutron irradiation appears to give rise to the formation of graphite. Deuteron irradiation caused colour changes in the surface layers (green for a *IIS* and brown for a *LS* diamond).

(7) There is no correlation between variations in the ratio of carbon-13 to carbon-12 in diamonds and the intensity of the characteristic *LS* bands.

It is clear from the foregoing results that there is probably more than one cause for the appearance of anomalous absorption in *LS* diamonds, since the absorption bands fall into at least two classes which exhibit different properties. Moreover, part of the absorption can be confidently assigned to the activation of normally forbidden frequencies of the ideal diamond lattice; but some of the bands appear to be due either to chemical impurities or to carbon atoms in an abnormal state. Isotopic effects cannot account for the anomalous absorption. Since deuteron irradiation fails to convert a *IIS* into a *LS* diamond, it seems unlikely that vacant sites are the cause of the *LS* anomalies.

Conclusions

Our present conclusion is that carbon atoms in an abnormal state and chemical impurities probably both contribute in varying degrees to produce *LS* diamonds. If some carbon atoms exist in a state which enables them to form double bonds in *LS* diamonds, then the bands near 1,530 cm.$^{-1}$ could be due to the vibration of carbon–carbon double bonds in an unsymmetrical environment, and the movement of the ultra-violet absorption edge towards 3000 A. is consistent with the introduction of a few conjugated double bonds into the structure. Since graphite is a more stable form of carbon than diamond, it is tempting to consider that in *LS* diamonds some parts of the structure have gone part of the way towards graphite. However, the neutron irradiation experiments seem to produce graphite without giving the typical *LS* features as an intermediate stage. With regard to chemical impurities, it should be realized that there is very good spectroscopic evidence[14] for the presence of many impurities in the average diamond, and some evidence[14] (although much weaker) that *IIS* diamonds are less impure than *LS* diamonds. This is a point on which we hope to conduct further investigations. The appearance of some very narrow absorption bands in group *B* (which do not seem to belong to the diamond lattice) is most easily explained by attributing them to the presence of chemical impurities.

What does seem certain from these investigations is that type I diamonds (specifically *LS* diamonds) are imperfect. This is an unexpected result, since in our experience all large diamonds of gem-stone quality are always type I diamonds. While some very small type II diamonds are perfect octahedra, all the large type II diamonds which we have examined are very far from any of the ideal crystalline forms of diamond (octahedron, cube, etc.) and, in fact, usually exhibit a layered structure with highly irregular faces and fractured edges. It would almost appear as though a large single crystal having the ideal Bragg structure is unstable and requires certain impurity centres to be incorporated to give stability. The beneficial effect of impurities in the growing of large single crystals is well known to workers in that field[15].

A full account of this work is now being prepared for publication in a more appropriate journal.

We are grateful for the loan of diamonds from Industrial Distributors, Ltd., Messrs. Triefus and Co., Lazare Kaplan and Sons, Inc., the late Prof. W. T. Gordon, Dr. K. Lonsdale, Prof. C. B. Slawson, Dr. W. C. Parkinson and Dr. H. J. Grenville-Wells.

We are very much indebted to Dr. Harmon Craig for making the carbon-13 – carbon-12 analysis for us. Some of the later phases of this work received financial aid from the U.S. Army Signal Corps under Contract *DA* 36-039 *sc*-5581.

WORLD POPULATION CONFERENCE IN ROME

THE World Population Conference which met in Rome during August 31–September 10 of this year was financed jointly by the United Nations and some of its Specialized Agencies, by certain governments, and by private institutions and individuals through the International Union for the Scientific Study of Population. It was the first international conference on this subject to be attended by participants from all over the world since the Paris Conference of 1937. Some four hundred persons participated, each of whom had been invited by the Secretary-General of the United Nations in his private capacity. Even though many held official positions in their own countries, they did not in any way represent their governments, and the Conference confined itself to discussion, and adopted no resolutions. A number of participants attended from the Communist countries, but there was none from the Chinese mainland although invitations had been issued to a number of Chinese known to be interested in the study of population. Prof. Liebman Hersch, professor of demography in the University of Geneva and president of the International Union for the Scientific Study of Population, was elected chairman of the Conference.

Many papers were submitted to the Conference and discussed in thirty-one different meetings. They dealt with a wide variety of topics, ranging from narrowly demographic problems, such as the nature and quality of vital statistics or techniques of projecting population figures, to wide issues such as the probable future development of population in a number of areas and the relation of such population to the available resources. Some meetings were devoted to fields in which a number of disciplines overlapped: thus anthropologists and demographers discussed methods of measuring population-growth in pre-literate societies; a session was devoted to the discussion of population genetics, and in another the relations between intelligence and fertility were studied. One meeting under the chairmanship of Mrs. Alva Myrdal, of the Division of Social Sciences of the U.N. Educational, Scientific and Cultural Organization, concerned itself with the social aspects of population changes, with special reference to inter-disciplinary studies.

From the wealth of documentary material presented it is difficult to pick out individual contributions, and in the rest of this article I can only comment on a few of the topics that were discussed. It is hoped that the papers submitted to the Conference will be published in the not too distant future.

Population trends and the probable future course of population naturally formed one of the main interests of the Conference, and a number of meetings were devoted to the discussion of these subjects. Mortality and fertility were discussed separately, and different meetings were devoted to the areas of the West in which mortality and fertility are low, and to Africa and Asia where both are high. Finally, in a meeting presided over by Mr. Harold F. Dorn, of the United States, the general prospects for future population changes were discussed.

A good deal of statistical and other information is, of course, available about Western countries. In those areas changes in mortality are unlikely to exert a major influence on total numbers in the near future; the main difficulty here lies in the assessment of the probable future course of fertility. It was pointed out that, in the past, predictions of future population growth have by no means been conspicuously successful, and there was marked predisposition to abstain from detailed forecasts for the future. But there seemed to be some consensus of opinion that although the small-family system has come to stay, the very low fertility-rates experienced by Western countries in the immediate pre-war period were exceptional. It was believed that in the majority of Western countries future growth will be very slow and that the rate of natural increase will not be far from replacement. In spite of the relatively advanced level of statistical development in those areas, the need for further data and continued research into the social factors influencing fertility was stressed. In particular, the lack of comparability between studies in different countries was adversely commented upon.

The position is completely different in Asia and Africa, where in general both fertility and mortality continue to be high and where data are scarce. In those areas the development of mortality is more important in determining likely future growth than are developments in fertility. It was pointed out that, in many of these areas, public health and other ameliorative measures have been successful in greatly lowering mortality and that this process may be expected to continue in the near future. In some areas these reductions in mortality have been achieved without any marked improvements in the nutrition of the people and without any major changes in the economic or social structure. Such reductions will naturally raise the rate of population-growth, and the rise in turn may react back on fertility-rates. It was pointed out that there are large regions of the world—Latin America was mentioned as an example—where an increased rate of population-growth caused by lower mortality might actually increase national welfare; but it was recognized that in some countries which are already densely populated—India and Japan were cited as cases in point—unchecked population-growth would in all probability react adversely on the standard of living.

It became clear in the discussion that many of the governments of the Asian countries are fully alive to the dangers of population-growth and are encouraging research on these topics. Such research has the aim of providing better data to help in the understanding of these problems and also in devising measures which would help to slow down the rate of increase. A number of important and interesting communications described field-studies in population in progress in India, Indonesia, Burma and Japan and in some parts of Africa. The application of sampling techniques to demographic research in particular has proved very fruitful. In India, the government is encouraging research on methods of birth control, and also conducting a field-survey, with the technical assistance of the United Nations, on the efficacy of the 'rhythm' or 'safe-period' method of birth control as a check on population in some Indian villages. It was clear that in societies in which there is a high degree of illiteracy, the introduction of even the simplest methods of birth control would be fraught with difficulty, although there was considerable evidence of a latent demand for it on the part of parents who have already had three or more children.

In contrast there were Prof. Y. Koya's findings in Japan. There, the dissemination of contraceptive information in a number of fishing villages has had the effect of reducing the general fertility-rate in those areas by about one-third within a fairly short space of time. The population of Japan is, of course, more literate than that of India; but the success of the experiment astonished the Japanese themselves, who were surprised by the absence of a demand for large families which they thought implicit in the Japanese system of values. Interesting facts were also presented regarding the response to the recent Japanese law which has legalized abortion on socio-medical grounds. Recent Japanese experience was cited in support of the views of those participants who believe that increasing industrialization would *ipso facto* bring with it lowered fertility. It was made clear, however, that even if fertility in the Eastern countries were to decrease as a consequence of industrialization and economic progress, the present age-structures of those populations are such that in any event considerable increases may be expected in the near future.

A forecast of the U.N. Population Division for the population of the world as a whole estimated that by 1980 the figure would lie between 3,300 and 4,000 million people, against an estimate of 2,500 million in 1950. This estimate was put forward with all due caution. There are many areas of the world for which the data are still rudimentary, and if recent reports putting the population of China at 630 million prove correct, even the basic estimate for 1950 may be in error by as much as 7½ per cent. In spite of this, it was considered valuable to have an extrapolation of present trends in different areas prepared by an impartial and expert body like the United Nations.

A word or two may be said about the attitude of participants from Communist countries. The absence of Chinese demographers has already been commented upon and was keenly felt in view of recent reports in the Press on the results of the latest Chinese enumeration. It was clear that there are considerable differences between the points of view of the Communist demographers and their Western and Asiatic colleagues. The Communists regard continued population-growth as a sign of a healthy society and refuse to be perturbed by the prospect of continued pressure of population upon resources. In a communication to the Conference, Mr. Ryabushkin, of the U.S.S.R., wrote: "The Neo-Malthusians proposed to bring the number of population into conformity with the level of production. But an elementary logic suggests that on the contrary levels of production should be brought into conformity with the number of population, because it is production that exists for population, but not population for production. And that production can be repeatedly increased in a relatively short period of time is evident from the historical experience of the Soviet Union."

This point of view, which implicitly assumes that natural resources are unlimited, has in practice aligned the Communists with the Roman Catholic Church in their attitude towards birth control. Neo-Malthusianism is a term of abuse, contraception is discouraged and it is not clear to what extent contraceptives are made available to those who desire them on other than medical grounds. Maternity and child-welfare services are available to mothers and high fertility is encouraged. But it is by no means clear from the addresses delivered at the Conference to what extent the right of individuals to decide on the size of family that they would like to have is recognized in Communist countries.

In concluding, tribute should be paid to the success of the administrative arrangements for the Conference, which was held in the building of the Food and Agriculture Organization, and to the skill of the interpreters, who were successful in providing simultaneous translation of addresses which were frequently highly technical into English, French, Russian and Spanish. E. Grebenik

POST OFFICE ENGINEERING RESEARCH STATION, DOLLIS HILL

OPEN DAY

The Post Office Engineering Research Station, Dollis Hill, was open to visitors from the universities, industry and government departments on September 24, the Press having been invited the previous day. The functions of the Station, its staffing and its relationships with the telecommunications industry remain much the same as on the last open day (see *Nature*, 168, 1022; 1951), though the buildings have since been increased, notably by one which provides a ground floor of nearly twenty thousand square feet devoted mainly to machine shops, an upper floor for drawing offices and part of another floor to a suite of laboratories devoted to thermionics. The individual problems being undertaken, whether basic studies or the development of new techniques or equipments to meet specific requirements, have, however, changed considerably, as the following descriptions of a few of the eighty exhibits presented will show.

The application of electronic techniques to telephone switching was shown in a private automatic branch exchange, devoid of electromechanical parts; it has an ultimate capacity of ninety-nine lines, exchange and extension, of which forty are now being connected. The switches use time-division-multiplex transmission, each line being allocated a fixed position, of duration 1 μsec., in a continuously repeated cycle of 100 μsec., for the transmission and reception of speech currents. Registers and markers control the switches. The former receives the numerical information from the calling subscriber and stores it on gas discharge tubes before passing it to the marker which causes the called line to be tested and, if free, to be connected to the electronic equivalent of a cord circuit to which the calling line was joined when the call originated. A register is in service for as long as it takes a subscriber to dial, the marker for about 20 m.sec.

The Station has designed an electronic digital computer called MOSAIC and installed it at an establishment of the Ministry of Supply. The computer could be shown, therefore, only by way of photographs of key parts. It uses a pulse repetition frequency of about 600 kc./s.; storage is in ultrasonic delay lines with a full capacity of 1,030 words (instructions) and numbers, each of 40 bits, that is, each number corresponds to twelve digits in the scale of ten. A four-address system is used: each instruction to the machine defines the location of the two numbers to take part in the next arithmetical step, the destination of the answer and the location of the next instruction. The instructions and the numbers to be operated on are fed in, and the answers fed out, on punched cards.

Recently new attempts have been made to extract the essential information in speech in such a way as to enable it to be conveyed over a channel of bandwidth much less than that conventionally used in telephony ($\sim$ 3,000 c./s.). It is well known that speech can be synthesized sufficiently well by using only six slowly varying parameters—the level and pitch of the larynx tone, the level of hiss excitation and the frequencies of the three major resonances (formants) in the vocal tract—but until now it had not been possible to extract the last three instantaneously from speech. Progress was demonstrated, however, with equipment which sets up a spectral display differentiated with respect to frequency to find the resonances. The display is followed by circuits which generate the control signals of a synthesizer. The six signals may require a total bandwidth of only 180 c./s., to which must be added, however, that required by the filter designer to ensure satisfactory assembly and separation.

Transistors have yet to make any impact on the telegraph and telephone systems in Great Britain, but some simple line amplifiers and a quartz-controlled oscillator using germanium junction transistors showed some of the advantages of small size and power consumption which may later be obtainable. The great and almost immediate susceptibility of fully exposed germanium junction diodes and triodes to water vapour at room temperature and at a pressure of about 1 cm. of mercury was demonstrated; the maximum voltage which the diode or the collector-base junction could sustain fell drastically—recovering equally rapidly on sudden lowering of the vapour pressure to below 1 mm. For reliability, therefore, water vapour must not be allowed access to the active element.

Two new pieces of spectrographic equipment were on show. A compact source unit can produce a d.c. arc, a high-voltage spark and some triggered arcs, and a projector-comparator enables spectra on one or two plates to be seen and compared at a magnification of twenty times for the purposes of identification and semi-quantitative analysis.

Magnetic materials, so widely used in telecommunications, have been the subject of several developments. Nickel–iron strip as thin as 0·00015 in. has been rolled by a novel technique; its low-field permeability can be as high as 20,000 and its coercive force as low as 0·025 oersted after suitable treatment; thicker material (for example, 0·002 in.), similarly treated, can have values of 75,000 and 0·0075 oersted.

Repeaters (amplifiers) for inclusion in submarine cables have engaged more and more attention since 1945 (the first one was laid by the British Post Office in the Irish Sea in 1943) and have continually thrown up new problems as submarine schemes became more ambitious. The practical solutions to some, such as that of making the gland between cable and repeater capable of preventing the entry of water at the pressures encountered at depths of a mile or two and that of making reliable all the components (the failure of any one of which could, without other safeguards, involve a cable ship in many days of work) often entail meticulous attention to detail with no spectacular results; they are, however, being obtained. Ingenuity in the electrical design of the amplifier has eased some of the problems. Much improved accuracy in the measurement of the electrical properties of submarine cables has been necessary to engineer some of the longer systems; when obtained, it has brought to light new effects affecting the properties. Progress towards an oxide-cathode valve of high performance and long life (perhaps twenty years) has been made using a passive platinum core, the fundamental behaviour of which is becoming understood, rather than the active nickel core so widely used in commercial valves. Careful attention must be continuously given to pre-processing, assembly and vacuum techniques.

British deep-sea repeaters, though still housed in rigid cases, are streamlined and more easily handled during laying than the earlier shallow-water types. Telemetering devices fitted within a dummy repeater, for measuring shocks, spin, inclination and pressure, have been developed in order to investigate the conditions encountered between the time a repeater enters the water and when it finally settles on the sea bed.

The Post Office continues to give much attention to the methods of producing quartz resonators; the Essen rings which the Post Office has recently supplied as standards to the Greenwich, Ottawa and Naval (Washington, D.C.) Observatories and to the National Physical Laboratory (Teddington), the National Research Council of Canada (Ottawa) and the National Bureau of Standards (Washington, D.C.) illustrate some of the newer techniques. The quartz is now cut by an annular saw which reduces waste and surface damage and permits thinner wafers to be specified.

Quartz continues to play a part in narrow-band filters. At the same time, coil-condenser filters, so widespread in multi-channel telephony, still find new uses in radio engineering. The output stages of a radio transmitter generate harmonics which, if the fundamental frequency is up to, say, 20 Mc./s., may interfere with the local reception of television, particularly in fringe areas; a low-pass coil-condenser filter capable of dissipating that fraction of the transmitter power at the fundamental frequency which it absorbs (perhaps 0·3 per cent or up to 50 W.), inserted between the output stage and the aerial, can sufficiently attenuate the harmonics. Filters play an increasing part in multi-channel microwave systems; Darlington's and Cocci's methods of network synthesis are being successfully applied to designs involving irises and posts in rectangular wave-guides.

The transmission of telephony and television at microwave frequencies could not be successfully undertaken without precision measuring equipment. Group-delay distortion of a frequency-modulated multi-channel telephony system results in intermodulation products of which little can be tolerated. The distortion introduced by filters, travelling-wave tube amplifiers and other components, over a bandwidth of 50 Mc./s. centred at about 4,000 Mc./s., can now be displayed on a cathode-ray tube with a sensitivity of 1 cm./mμsec.

Equipment for long-distance radio communication in the 4–30 Mc./s. band is judged in part by its ability to combat the fading and multipath effects characteristic of ionospheric propagation. Because testing in service is slow and inconvenient, a fading machine simulating the natural effects is a great asset. An early machine, producing frequency-selective fading by combining two or three differently delayed signals of constant amplitude, but varying relative phase, has recently been modified so that the differently delayed signals individually fade in a near-random way, more closely simulating field conditions.

NEWS and VIEWS

Nobel Prize in Physics:

Prof. Max Born, F.R.S.

PROF. MAX BORN, who has been awarded a share of the Nobel Prize in Physics for 1954, is known for many contributions to modern theoretical physics, particularly to the development of quantum mechanics and to the theory of crystals. The work mentioned specifically in the announcement of the Nobel award is the interpretation of the wave functions as probabilities for the positions of particles, a vital step in the development of the modern view of the relations between particle and wave aspects of atomic theory. This dates from a period when, in collaboration with Heisenberg and others, Born took an important part in the development of quantum mechanics, which form one of the two independent approaches to modern quantum theory. Other important work of that period, which has become classical, includes his use of perturbation theory for scattering problems and the Born–Oppenheimer theory of molecules. The theory of crystal lattices has formed another continuing interest, from the earliest papers which showed the basic ideas of lattice vibrations and their relation to the inter-atomic forces, to several treatises covering all aspects of the theory. Born has also taken an active interest in many other aspects of quantum theory. His effect on theoretical physics should, however, be measured not only by his own papers, numerous as they are, but also by the work of his pupils. His school at Gottingen was for a long time one of the most important centres to which young theoreticians went to find guidance and inspiration and to be infected with that enthusiasm and optimism which characterize Born's own work. The men who worked with him later at Cambridge and Edinburgh also include many who have made their mark on modern physics.

Prof. W. Bothe

PROF. W. BOTHE, of the University of Heidelberg, who shares the 1954 Nobel Prize in Physics with Prof. Born, is known for many important contributions to modern physics. The best known of these include his introduction of coincidence methods into counting techniques and the work in which, together with Geiger, he applied the coincidence method to the Compton effect and showed that the conservation laws are satisfied in each individual event and not merely on the average. This was fundamental for the interpretation of atomic processes. With Kohlhorster he applied coincidence methods to the study of cosmic rays and thus helped to establish the presence of penetrating charged particles. Later, in the course of systematic work on nuclear reactions, he discovered the unusual radiation, emitted by beryllium under α-particle bombardment, which was later identified as neutrons. Other fields in which he did pioneer work include the study of hard γ-rays and the nuclear photo-effect produced by such rays and the problems of multiple scattering of electrons and of neutrons. On problems of scattering he has not only done experimental work of great importance but has also made valuable contributions to the theory.

Nobel Prize for Chemistry:

Prof. Linus Pauling, For.Mem.R.S.

THE Nobel Prize for Chemistry for 1954 has been awarded to Prof. Linus Pauling, of the California Institute of Technology. This award will be acclaimed by chemists of all kinds, for Prof. Pauling's contributions have brought about a revolution in the entire field of chemistry. His early work was concerned with the determination of crystal structures by X-ray crystallography, an interest which he has retained; his recent views on the constitution of proteins are based largely on detailed crystallographic analyses of amino-acids and peptides. The study of crystal structure led him to consider the nature of chemical bonds, and already in 1926 he published a remarkable paper on the structures of benzene and its analogues in terms of the Bohr atom. This, however, was soon followed by an impressive series of papers in which the new methods of wave mechanics were applied to chemical problems of all kinds, and in which the resonance theory was developed as a general qualitative approach to such problems. This work led to the recognition of additivity of bond energies and covalent radii in unconjugated molecules (that is, those with a unique classical structure), to the concept of resonance energy and intermediate bond character in conjugated molecules, and to the concept of electronegativity as a factor in determining covalent bond energies. Prof. Pauling's original tables of bond energies, covalent radii and electronegativities are still widely used, and later work has altered them only in detail. Many of these covalent radii were deduced from bond-lengths measured in his laboratory by the newly developed and difficult technique of electron diffraction. In recent years Prof. Pauling has made further notable contributions in fresh fields: a new theory of the metallic state, a theory of immunochemical reactions, and new structures for polypeptides and proteins. Last but not least, he combines with all his other talents a remarkable gift of exposition; the impact of his work on the chemical world has been due largely to the brilliant lucidity of such treatises as "The Nature of the Chemical Bond".

Memorial Tablet to Sir William Herschel

ON November 8 a memorial tablet was dedicated to Sir William Herschel in Westminster Abbey, not far from the graves of Newton and of Sir John Herschel, the son of Sir William. Newton had been buried in the Abbey in 1727, but it appears that at the time of Herschel's death in 1822 it had not been recognized that outstanding men of science should be buried there. From the epitaph on Herschel's grave at Slough, it is clear that his contemporaries realized that he had been one of the greatest astronomers of all time. He was known as the discoverer of the planet Uranus and of great numbers of double stars, star clusters and nebulæ. Some of these discoveries had been made when he was attempting to determine the distances of stars by their parallactic displacement; and although he had failed to determine the distance of any stars, he formed estimates which were not much in error. He had himself constructed telescopes of far greater power than any made by the instrument makers of that time for use in the national observatories, and the observations he made with these instruments made him the founder of sidereal astronomy on an observational basis. He was a pioneer in collecting and discussing astronomical statistics. He conceived our galaxy as the great flattened system it is. He determined the motion of the sun and planets through that system. He believed that some, at least, of the nebulæ might be island universes, that is, systems comparable with our own Milky Way but lying far beyond it. As there was no one with instruments comparable in light grasp with his, and no one with his great experience in observing, some of his ideas remained dormant until in the present century they could be taken up with the great Californian reflectors in combination with fast photographic plates.

The cost of the tablet in Westminster Abbey has been borne by Mr. J. E. Bullard, who had pointed out the absence of any memorial and the desirability of having one to the greatest of British observational astronomers. The service was conducted by the Dean of Westminster, Dr. A. C. Don, and an address on Herschel was given by Dr. J. Jackson, president of the Royal Astronomical Society.

Royal Society Medal Awards for 1954

THE following awards of medals have been made by the President and the Council of the Royal Society:

Copley Medal to Sir Edmund Whittaker, emeritus professor of mathematics in the University of Edinburgh, for his distinguished contributions to both pure and applied mathematics and to theoretical physics.

Rumford Medal to Dr. C. R. Burch, of the H. H. Wills Physics Laboratory, University of Bristol, for his distinguished contributions to the technique for the production of high vacua and to the development of the reflecting microscope.

Davy Medal to Dr. J. W. Cook, principal of University College, Exeter, recently regius professor of chemistry in the University of Glasgow, for his distinguished fundamental investigations in organic chemistry.

Darwin Medal to Dr. E. B. Ford, reader in genetics, University of Oxford, for his distinguished contributions to the genetical theory of evolution by natural selection, particularly in natural populations.

Hughes Medal to Mr. Martin Ryle, lecturer in physics, University of Cambridge, for his distinguished and original experimental researches in radio astronomy.

Nature Conservancy: Scientific Research

IN an adjournment debate in the House of Commons on October 22, Mr. Geoffrey de Freitas, one of the two members of Parliament who are themselves members of the Nature Conservancy, directed attention to the work of the Conservancy, particularly to research work being carried out and the importance of both adequate finance and public understanding if the work of the Conservancy is to be effective. With regard to research, Mr. de Freitas said that, in accordance with a suggestion of the Waverley Committee in its report on coastal flooding, the Nature Conservancy has again investigated the possibility of using vegetation to stabilize the shifting coast-line and, in co-operation with the Somerset River Board, is experimenting in this way in Bridgwater Bay. In co-operation with the Agricultural Research Council and other bodies, it is also examining the effect of spraying roadsides to kill weeds. So far as the Conservancy can judge, spraying has not proved effective in killing the most troublesome weeds, and it appears that indiscriminate spraying is doing real damage to insect life and small fauna. Before the outbreak of myxomatosis in Britain a year ago, the Conservancy asked Mr. R. M. Lockley to investigate the matter, and his survey of the problem, its repercussions and the progress of the disease has proved a valuable guide. Mr. Lockley has concluded that the rabbit flea is the most important transmitter, and work is still being done in studying the consequence of the drastic reduction in the rabbit population on vegetation and animal life.

Finance and Land Transference

APART from finance and the bearing of public relations on the prosecution of fundamental research, Mr. de Freitas raised the question of the policy of land transference in connexion with the Conservancy. Replying on the debate, Mr. J. R. Bevins, parliamentary secretary to the Ministry of Works, promised to bring before the Chancellor of the Exchequer the question of land transference and the use of the National Land Fund for the Nature Conservancy. He pointed out, however, that the Conservancy already possesses powers of compulsory purchase under the National Parks and Access to the Countryside Act, 1949, but these powers have not been invoked and they are not to be used without the sanction of the Lord President of the Council. With regard to finance, the present annual expenditure of the Conservancy is about £200,000, and in this context Mr. Bevins stated that government expenditure on civil research is at the present of the order of £20,000,000 a year. Referring also to the ploughing up of sites of scientific interest, Mr. Bevins stated that the problems involved here are being discussed between the Nature Conservancy and the Ministry of Agriculture, and also with the National Farmers Union and the Council for the Preservation of Rural England.

Nuffield Foundation Support for Research in Rheumatism

During the past five years the Nuffield Foundation has been supporting much chemical and other work on adrenal hormones, but, with the gradual fading of the original hopes of cortisone and adrenocorticotrophic hormone as panaceas for the chronic rheumatic diseases, the Foundation is now reverting to its original policy of supporting fundamental and clinical research into the nature of the rheumatic diseases. As in the past, this programme will be supported both from the resources of the Oliver Bird Fund, which was created in 1948 by the gift of £450,000 from Captain Oliver Bird, and from the Foundation's original Nuffield endowment. Two large grants and two smaller ones are being made. The Foundation has made a grant of £70,000 to the University of Manchester, payable over the next eight years, to extend the work of the rheumatism centre under the director, Prof. J. H. Kellgren, professor of rheumatology in the University. This will be an addition to the original grant of £100,000, spread over ten years, which was made in 1946 to establish a pioneer centre in Manchester of the kind advocated by an expert medical advisory committee of the Ministry of Health at the end of the Second World War. For the past five years the Foundation has been supporting, with general grants for research staff, the clinical and fundamental work of the rheumatic unit directed by Dr. J. J. R. Duthie, senior lecturer in the Department of Medicine, University of Edinburgh. This unit, sponsored by the University to promote teaching and research in chronic rheumatism and to improve standards of treatment, was opened in the Northern General Hospital in October 1947. Limited accommodation has always been a handicap, and a new building is being erected on a site adjoining the unit's ward at the Northern General Hospital. This building, which will be associated with the name of Captain Oliver Bird, will have consulting and research rooms, clinics and laboratories. £27,000 has been given to meet the cost of the building and its furnishing, and in addition, the Foundation will continue its annual grant to assist the unit's work, £38,000 over the five years 1954–58 being provided for this purpose. The two smaller grants are as follows: £8,000 to the University of Sheffield to finance a research fellowship in the Sheffield Centre for the Investigation and Treatment of Rheumatic Diseases, directed by Dr. H. F. West; and £6,000 to the Oxford Regional Hospital Board for an experimental pathologist to work under Dr. A. G. S. Hill on the pathogenesis of rheumatic diseases at the Rheumatic Diseases Research Centre at Stoke Mandeville Hospital.

Hungarian Scientific Exchanges

In September 1953, when the Hungarian Federation of Scientific and Technical Societies acted as host in Budapest at the Third Assembly of the World Federation of Scientific Workers, it was announced that it was intended that scientists from Western countries should be invited to Hungary in future years. This proposal was, in fact, carried out this year. Ten British and French scientists were invited to spend three weeks in Hungary, partly at the holiday resort on Lake Balaton and the rest of the time in visiting scientific institutes. Altogether, some one hundred and thirty individual visits were made, and every facility was given for the visitors to meet those working in their own fields of research. The visitors gave seventeen lectures to various sections of the Hungarian Federation. It is intended that invitations shall be extended to Hungarian scientists to visit Great Britain and France during the summer of 1955, so that the initiative of the Hungarian Federation in attempting to improve communication between scientists in the West and the East shall be followed up and, if possible, improved upon. Members of learned societies who might be interested in such exchanges should write to the Secretary-General of the World Federation of Scientific Workers, 15 Half Moon Street, London, W.1.

Rust Infection Studies

An important study of the infectivity of single-spore strains, that is, physiological races, of the brown rust fungus (belonging to the group species *Puccinia dispersa*) to brome grasses, undertaken during a period of fourteen years, has now been reported on by J. Bean, P. W. Brian and F. T. Brooks (*Ann. Bot.*, N.S., 18, 129; 1954). Each rust strain was maintained as a stock culture on a suitable host, kept permanently under 'Cellophane' covers to prevent contamination. The method of inoculation and techniques used to prevent cross-infection are described. By their infection reactions on a representative selection of *Bromus* spp. at least five physiological races have been characterized. Two of these have host-ranges confined to a single section of the genus, but others have a much wider host-range within the genus. The uredospore stage of all was identical. Studies of the teleutospores have been limited and knowledge of the species of rust involved is incomplete. All belong to the group-species *Puccinia dispersa* Erikss. and Henn.; the species *P. bromina* Erikss. and *P. symphyti-bromorum* Müller were included among the cultures studied, possibly also *P. bromi-maximi* Guyot. In a large series of inoculations, over a period of in all fourteen years, all physiological races have been remarkably stable in their infection types and host-range, and no confirmation of Marshall Ward's 'bridging-host' theory has been obtained. Cultivation of two physiological races for 164 generations on *Bromus arduennensis*, a species considered by Ward to have special significance as a bridging-host, induced no changes in their host-range.

Engineering Study of the Southern Californian Earthquakes

A detailed study of damage to buildings and other structures caused by the earthquake of July 21, 1952, has been published by the Seismological Society of America under the title of "An Engineering Study of the Southern Californian Earthquake of July 21, 1952, and its Aftershocks", by Karl V. Steinbrugge and Donald F. Moran (*Bull. Seis. Soc. Amer.*, **44**, No. 2*B*, 199 (April 1954). 2 dollars). The earthquakes, with the number of shocks shown in brackets, occurred on the following days: July 21 (7), 22 (2), 23 (3), 25 (3), 29 (2), 31 (1), and August 1 (1) and 22 (1), 1952. A further shock occurred on January 12, 1954. The epicentre of the first shock was at Wheeler Ridge, lat. 35° 00′ N., long. 119° 02′ W., and its magnitude was 7·6. The aftershocks, of lesser magnitude, were a little to the north and east of the first shock, in Kern County. The study includes sections on damage to structures, schools, dams, roads and bridges, and the earthquake effects on oil production and agriculture. Appendixes detail effects on particular buildings, such as Brock's

Department Store and Kern General Hospital. It is concluded that one- and two-story buildings, designed to resist earthquake forces, generally suffered no damage. No internal failures were found in wood diaphragms (straight or diagonally sheathed) or in steel diaphragms, although fastening details were deficient. Excessive deflexions of these diaphragms may have contributed to wall cracking, and contributed to failures along the diaphragm boundaries. The hazard to life of parapets on street fronts has been recognized. The use of competent technical help is necessary where earthquake resistance is desired; and if earthquake insurance is a factor, structures (in California) should be designed to meet the Pacific Fire Rating Bureau recommendations.

Scholarships for Personnel Management

An allocation to the Institute of Personnel Management from Counterpart Conditional Aid Funds has made it possible for the Institute to award a small number of scholarships designed to assist men and women, not less than twenty-four years of age, who are already in industry or commerce, to attend full-time courses of training in personnel management at one of the following: London School of Economics; College of Technology, Manchester; Glasgow and West of Scotland Commercial College and Royal Technical College (jointly); University College, Cardiff; and the University of Liverpool (post-graduate course in industrial sociology). The scholarships, which are tenable for one year, will amount to £300, with a dependants' allowance of £100 for a married candidate with one or more children and, in special circumstances, an additional grant not exceeding £50. Application forms, to be returned by January 31, can be obtained from the Secretary, Institute of Personnel Management, Management House, 8 Hill Street, London, W.1.

Geneva Laboratory of the Battelle Memorial Institute

On the occasion of the official opening on November 20 of a research laboratory in Geneva of the Battelle Memorial Institute, a symposium will be held on "The Influence of Scientific Research in the Modern World". The speakers at the symposium will be Prof. G. Colonnetti, president of the National Research Council of Italy; Prof. L. Jacqué, of the École Polytechnique, Paris; and M. Denis de Rougemont, director of the European Centre for Culture. A number of representatives of industry and finance in Belgium, France, Italy and Switzerland have been invited to participate at the symposium. On the same day the laboratory will be open for inspection. Further information can be obtained from the director of the laboratory at 7 Route de Drize, Genève-Carouge.

Precision Electrical Measurements: Symposium at Teddington

A symposium on precision electrical measurements will be held in the National Physical Laboratory, Teddington, during November 17–20, the last day being reserved for a visit to the Electricity Division of the Laboratory. The other days will be devoted to five sessions on the following topics (with the chairman shown in brackets): capacitance and dielectrics (Dr. L. Hartshorn); inductance and magnetics (Mr. B. G. Churcher); electrotechnics (Mr. R. S. J. Spilsbury); high-voltage measurements (Dr. L. G. Brazier); and high-voltage impulse-testing techniques (Mr. R. Davis). Further information can be obtained from the Director, National Physical Laboratory, Teddington, Middlesex.

Mineralogical Society: Officers and Council for 1954–55

The following have been elected officers and members of council for 1954–55 of the Mineralogical Society: *President*, Prof. L. Hawkes; *Vice-Presidents*, Dr. F. A. Bannister and Dr. F. Dixey; *Treasurer*, Prof. J. H. Taylor; *General Secretary*, Dr. G. F. Claringbull; *Foreign Secretary*, Dr. L. J. Spencer; *Editor of the Journal*, Dr. L. J. Spencer; *Ordinary Members of Council*, Mr. B. W. Anderson, Mr. S. H. U. Bowie, Mr. T. Deans, Prof. W. A. Deer, Prof. K. C. Dunham, Mr. P. M. Game, Dr. A. G. MacGregor, Dr. S. R. Nockolds, Dr. F. C. Phillips, Mr. L. A. A. Thomas, Dr. E. A. Vincent and Dr. M. K. Wells.

Italian Genetics Society

An Italian Genetics Society (Associazione Genetica Italiana) has been formed with the aim of uniting all Italian workers in genetics to further knowledge in this field. Officers for the current year are as follows: *President*, G. Montalenti; *Councillors*, C. Barigozzi, A. Buzzati-Traverso and A. Chiarugi; *Secretary-Treasurer*, G. Magni (Istituto di Genetica, Università di Pavia).

Announcements

The Duke of Edinburgh is to open officially the new laboratories of the Research Association of British Rubber Manufacturers at Shawbury, near Shrewsbury, on November 23.

The Franklin Medal of the Franklin Institute, Philadelphia, has been awarded to Dr. C. E. Kenneth Mees for his "contributions to knowledge of the photographic process and for his development of the first organized scientific laboratory in the United States which resulted in new products advancing the photographic process". The Medal is awarded annually "to those workers in physical science or technology, without regard to country, whose efforts . . . have done most to advance a knowledge of physical science or its applications".

The Royal Agricultural Society of England has decided to offer annually a medal together with an award of a hundred guineas for research work of outstanding merit carried out in the United Kingdom which has proved, or is likely to prove, of benefit to agriculture. The award will be known as the R.A.S.E. Research Medal. Heads of university departments, research stations and institutes, and other research establishments should submit to the secretary, Royal Agricultural Society of England, 16 Bedford Square, London, W.C.1, in January of each year, the name of any member of their staff they may wish to recommend for the award. No direct applications by candidates will be considered.

Reference was made in *Nature* of September 25 to the position in the United States of Dr. J. R. Oppenheimer. We are informed that copies of the relevant documents are available from H.M. Stationery Office (York House, Kingsway, London, W.C.2, and provincial depots); they are the "Transcript" of the evidence (price 23*s*. 6*d*.; by post, 24*s*. 9*d*.) and "Documents and Letters" (price 2*s*. 3*d*.; by post, 2*s*. 6*d*.).

LIBRARY ASSOCIATION

ANNUAL MEETING

IN his presidential address to the Library Association on September 28, Mr. C. B. Oldman, principal keeper in the Department of Printed Books, British Museum, considered three or four general questions relating to the keeping of books. Are libraries, as at present organized, doing all that they should to ensure the preservation of recorded knowledge, as well as facilitating its dissemination? Is the emphasis to-day too much on the supply of day-to-day requirements, including specialized information for the research worker? Is the general, comprehensive library already outmoded, or should there continue to be at least one library aiming, as (in theory, at any rate) the British Museum Library at present does, at acquiring everything and keeping everything that it acquires?

These are obviously questions bearing closely on the proposals for library reorganization that are implicit in the project for a Science Centre, and, although not limiting them specifically to science and technology, Mr. Oldman's remarks in the final section of his survey were concerned especially with the general research library, of which the British Museum is the acknowledged chief. Referring briefly to the functions of the specialist libraries, in stressing the importance of such libraries being able always to supply their users with the latest information, he perhaps overstressed the extent to which this permits such libraries to discard freely what was once important. Nevertheless, he correctly indicated the inadequacy of most such libraries for historical purposes, even in the field in which they specialize, and in pointing out that the term 'research' is often misapplied, for example, to hunting for information, he reminded his audience that science has no monopoly of research, if one defines research as original investigation involving the search for untapped or hitherto imperfectly appreciated sources and the drawing of new conclusions from what is found.

The discussion of the function of research libraries has so far not been very conclusive, and Mr. Oldman, in pointing out that what distinguishes the great research libraries is the large proportion of research material they contain, remarked that their strength derives from the extent as much as from the character or quality of their accumulations, and this is the root of the problem confronting them. If the great research libraries of the world continue to grow as they have in the past half-century, and if, while retaining all that has been already acquired, they are to endeavour to meet the new demands that are constantly being made upon them, with the multiplication of faculties and the springing up of new fields of study, they must face a prospect of infinite expansion, with all the problems of accommodation, staffing and finance involved. In the United States, in particular, they are beginning to wonder whether they will not be forced to call a halt. Mr. Fremont Ryder in 1944 estimated that, on an average, the American university library is doubling its stock every sixteen years, and in different degrees the same problem faces the whole group of general research libraries. So far as the British Museum is concerned, within a few years the present policy will lead to saturation point, and a new library on a new site will be required. Nevertheless, Mr. Oldman thought that completeness should remain the target and, when it is no longer possible to pursue the present policy, he suggested that it would be better to create separate subject libraries which will remain constituent parts of the one national library rather than to reduce current holdings or future intake. Such problems clearly demand close consideration in formulating plans for a national reference library for science and technology.

Several other papers presented at the conference were also of general interest to the scientific worker. Two papers read on September 30, for example, dealt with standards of service and the individual library and its place in the national system. In the first of these, Mr. J. H. Haiste, of Rugby, dealt with the question of standards and co-operation generally from the point of view of the library of the smallish authority, representing about a quarter of all library authorities in Great Britain. Mr. Haiste insisted that the service provided by such a library must be in harmony with the community it serves, but on the highest possible level for that community, and he thought that failure to adjust service to the conditions and needs of the community is mainly responsible for the failure of the library service in Britain to achieve its proper status. While fully recognizing the difficulties and disadvantages of the smaller library, Mr. Haiste thought that it should be less docile about its limitations: a cleaner, clearer scheme of co-operation would make for better standards of service, but the energy is derived from the individual libraries in each region able to do their own communal jobs first, and willing also to accept responsibility for providing on their own shelves a strong subject representation for the general benefit. He agreed with the Vollans's report that the most effective contribution the individual library can make to the success of library co-operation is to improve its own bookstock and its services to its own readers.

The second paper, by Mr. A. H. Chaplin, deputy keeper in the Department of Printed Books, British Museum, was concerned with the place and function of the British Museum. Describing the position of fundamental importance which the Museum occupies in building up a comprehensive national stock of books and the way in which the policy already indicated by Mr. Oldman is implemented, Mr. Chaplin, before he went on to consider the important contribution made by the Museum to the complete national bibliography, noted some classes of printed matter of potential historical interest which, although technically 'published', often failed to reach the Museum. There is, however, also need for a centre for co-operative work in supplementing the information contained in the original "Short Title Catalogue" of English books printed down to 1640, in Wing's list of English books published between 1640 and 1700 and in such lists as the "English Catalogue", relating to the nineteenth and twentieth centuries. Mr. Chaplin believes that the resources of the Museum and of a number of other important libraries could be both more economically and more effectively used if there were close co-ordination between them in their purchases of foreign books. The British Museum does not to-day attempt to cover systematically certain kinds of foreign publications, particularly scientific and technical literature, but there is no certainty that the publications not taken by the British Museum will be found in some other British library, still less that, if acquired, they will be preserved. He suggested that the consultation and co-operation in this field already begun between the British Museum and other government libraries should be extended to the various national and university libraries and put on a systematic basis. Each library, while continuing to acquire the publications likely to be called for by its own readers, would undertake responsibility for acquiring, in particular fields to be allotted to it, the publications which, because of their obscurity or very restricted interest, are at present neglected. The British Museum, apart from developing more thoroughly its collections in the fields where it is already particularly strong, would acquire the books to which no one else is prepared to give house-room and would store those which every other library would prefer to discard. A natural corollary of such a system of co-ordination would be the making of a union catalogue of all the books to which it applies, giving at least one location for each book. In conclusion, Mr. Chaplin indicated the willingness of the Museum authorities, as part of any such projects, to make, after wide consultation, such changes in Museum practices as would bring them into harmony with the majority of co-operating libraries and remove present obstructions. Any such scheme, however, would require greatly increased resources in staff, in money and in buildings, and they will only be forthcoming if these demands are presented to Parliament backed effectively by influential opinion.

The place of the non-public library in the library system was considered by Mr. E. A. Baker, librarian in the Ministry of Food, in a paper also read on September 30. Stressing the need for greater co-operation between all types of libraries, Mr. Baker suggested that each public library participating in one of the subject specialization schemes recently set up in some of the regional bureaux should be able to look to a specialist library in its particular field for assistance in book selection and bibliographical information. He also suggested that the time has come for a thorough investigation into the constitution and organization of the Library Association with special reference to the representation of the non-public libraries.

Mr. W. B. Paton's paper on "Standards of Library Staff: Recruitment and Training", read on September 29, stressed the dependence for success of a library service on the quality of its staff. The general education of librarians should, he maintained, reach the standard at present demanded by the Library Association from examination candidates, and for preference should surpass it. This could be possible if the same rigid standards were not applied to the non-professional categories whose service is likely to be temporary. He also thought the division of staffs into professional and non-professional categories should become the declared policy of the Library Association as soon as possible, that university graduates should be welcomed as recruits to the library service and that in time this would be a normal standard of entrance. He urged that the time has come for the Library Association to reconsider its examination syllabus to relate it more closely to the needs of special libraries. He also suggested that the conduct of the examinations should be integrated with the activities of the schools of librarianship. The number of these schools should be reduced, but the qualifications of their teaching staffs should be raised and opportunity sought to link the schools with universities. A personal interpretation of the office of librarian, given by Mr. F. Raymond Smith, librarian of the Guildhall, on September 28, also stressed the importance of the professional ideal and discussed the closer adjustment of professional training to the needs of special libraries, and the related issues of the common structure and functions of both special and municipal libraries and librarians. On October 1, Mr. Bengt Hjelmqvist, head of the Library Board in Sweden, described the operation of public libraries in Sweden under fifty years of State aid.

FIFTH INTERNATIONAL SPECTROSCOPY COLLOQUIUM

THE fifth International Spectroscopy Colloquium, organized by Prof. F. X. Mayer, chairman of the Spectrochemistry and Colorimetry Group of the Austrian Society of Chemists, was held at Gmunden, Salzkammergut, Upper Austria, during August 30–September 3. More than five hundred members attended, representing twenty-three countries, and the importance to practical spectroscopy of these international gatherings is shown by the significant increase in the number of participants on each successive occasion. Two days were allotted to each of the principal sections—emission spectroscopy and molecular spectroscopy—with a mid-week excursion to the Nitrogen Works and Steel Works at Linz. The meetings were held at the Town Theatre, while a one-day symposium on direct-reading spectroscopy was held concurrently at the Kurhotel.

Emission spectroscopy. Three papers dealt with the analysis of silicates and silicate rocks and similar materials, for which various types of arc excitation are used. Progress in the detection of sulphur and halogens by high-current, low-voltage, short-duration spark discharges was reported, followed by studies of arcs and sparks in different atmospheres, highly reproducible 'sparking-off' phenomena and the stroboscopic examination of controlled sparks. A new atomizer using electrostatic spraying for flame analysis was described, and the use of amyl alcohol has been found to give a three-fold increase in accuracy and sensitivity in detecting calcium and magnesium.

Further studies of the Standard Paper Density Scale were discussed; improved results have been obtained with scale lines having a profile similar to that of spectrum lines. In determining the absolute error of photometric measurements, the use of polarization prisms is least open to objection, provided that the prisms are in perfect condition. Other subjects included errors in the 'method of additions', calibration with the rotating step-sector and devices for producing linear calibration graphs. Advances in equipment concerned microphotometers (one incorporating a recording electro-dynamic oscillograph, and the other an electric comptometer with a printing device), stigmatic grating spectrographs, and a plane grating in convergent light for the study of hyperfine structure and isotope shifts.

Direct-reading spectroscopy. A new universal quantometer and two British designs of the polychromator type (a grating instrument and an attachment to a quartz instrument) were described. Other papers dealt with the analysis of aluminium alloys and steels, the use of the reflected image as an internal standard and a systematic study of iron + nickel + 1 per cent chromium and iron + cobalt + 1 per cent chromium alloys.

Molecular spectroscopy. Analytical applications of emission and absorption spectra in the vacuum ultra-violet were reviewed; photo-ionization of oxygen and other gases was reported in this region of the spectrum, and cross-sections have been calculated from intensity measurements. Other contributions dealt with the structure and composition of siliceous materials, the estimation of the insecticide parathion and the identification of components of fats and metal soaps.

A method of correcting ultra-violet spectra of macromolecules (proteins) for Tyndall or Rayleigh scattering was described. Changes of spectra with *p*H have been assigned to ionization of phenolic groups of tyrosin in albuminoids. The results given on double bonds in relation to the dependence of Raman line intensities on excitation frequency are not in accord with Placzek's theory. Vibration-rotation bands of O_2, CN, CH and CO in infra-red flame spectra and determinations of flame temperatures were discussed. Microwave data on deuterated derivatives indicate the exact structure of the pyridine molecule, and the effect of solvent and hydrogen bonding on the dipole moment of pyrrole is related to shifts in the NH frequency. Work on hydrogen bonding, particularly water in silica gels, was reviewed. It is concluded from infra-red studies of structure and intermolecular interactions of the amide group that dipole–dipole interaction rather than hydrogen bonding is the controlling factor in polyamide and polypeptide structures. Many overtone and combination bands have been identified in near infra-red spectra of polypeptides and proteins, using polarized radiation. Studies of the spectra of amorphous and crystalline celluloses, using the hydrogen–deuterium exchange, were reported, and the ultra-violet absorption of cellulose xanthogenate has been analysed by analogy with simpler organo-xanthates.

New designs of spectrophotometers and a partly mechanical, partly electronic, 'memory system' for converting a single-beam spectrometer to give percentage absorption traces were described. A punched-card system of documentation was demonstrated, and the 1954 Ohio State meeting was reviewed. In addition, three papers were presented on X-ray fluorescence spectroscopy.

The innovation of holding pre-arranged evening discussions proved successful, and it is hoped to extend this feature on future occasions. The four topics selected were: experiences with methods not requiring standards for comparison, using different techniques; the evaluation of spectrograms (in this discussion the desirability of international standardization of symbols, definitions and analytical methods was stressed and referred for action at the next Colloquium); a comparison of relative sensitivities of the eye, the photographic emulsion and electrical radiation receivers, in spectrophotometric work; and the equipment and technique of Raman spectroscopy—its analytical possibilities and scope in comparison with infra-red methods.

A somewhat fuller summary of the proceedings of the Colloquium, giving the authors and brief notes on the papers presented, is being published in a "Spectroscopic Conferences Supplement" to the forthcoming December issue (No. 14) of the *British Bulletin of Spectroscopy*. A complete record of the papers and discussions will be published in a special volume of *Microchimica Acta* (Springer-Verlag, Vienna) in 1955. Proposals for the Sixth Colloquium were discussed at a committee meeting attended by delegates from fourteen countries. Possible broadening of the scope to include the physics of spectra, with joint or consecutive meetings with other bodies, was considered. However, it was decided to continue the organization on lines similar to those of previous occasions, but with more emphasis on prearranged discussions on selected topics. It was finally agreed that the next Colloquium should be held in Holland in the autumn of 1956.

D. M. SMITH

APPLIED RESEARCH IN TECHNICAL COLLEGES

A SPECIAL committee of the London and Home Counties Regional Advisory Council for Higher Technological Education has issued a report on applied research in technical colleges*, based on information supplied by seventeen out of the twenty-five colleges in the region approached by the committee. The Council is satisfied that the report covers substantially all the published research undertaken in technical colleges in the region during 1947–52, and some 330 original contributions to scientific or technological knowledge are listed in an appendix, the great majority being in physical, inorganic and, especially, organic chemistry. There is also some bias towards biology; but the Council comments that relatively few of the published researches in organic chemistry appear to have been undertaken in direct co-operation with industry.

An appended list of research projects undertaken at the direct request of industry indicates that technical colleges have helped and are helping in the investigation of engineering problems in circumstances in which no question of publication arises, and a further appendix gives examples of co-operation between technical colleges, research organizations and government departments, including the Department of Scientific and Industrial Research. The Council considers, however, that there is room for a considerable increase in the amount of work done in consultation with industry or for industry's direct benefit, and supports the view that one important function of technical colleges is to train research technologists for industry (especially, perhaps, for the engineering industry) and that fundamental research provides an admirable training in research methods. It suggests that here the technical colleges could be of particular assistance to the small firm, and that the investigations now in progress by part-time students, possibly working for a master's or a doctor's degree, represent a fruitful line of co-operation by which the resources of the colleges may, by agreement, be used by an individual nominated by a firm to conduct a relatively long-term investigation in which the firm is interested. An appendix to the report shows that during the period four doctorates in science, 105 Ph.D.s and 104 M.Sc. degrees of the University of London were awarded for research carried out in the technical colleges of the region.

* Applied Research in Technical Colleges. Pp. 44. (Publication No. 18.) (London: London and Home Counties Regional Advisory Council for Higher Technological Education, 1954.) 2s. 6d.

Since January 1950, about two dozen posts of research assistant or demonstrator have been approved in London and the home counties. Most of these have now been filled, and at about a dozen colleges research by staff and advanced students is accepted as a normal part of the curriculum. At other colleges, research by members of the staff is recorded and the report emphasizes that staff of the calibre required will never be attracted unless some opportunity for original research is provided. The close contact of the staff with neighbouring firms should avoid any difficulty in suggesting lines of investigation likely to be of service to local firms, nor should members of the staff necessarily be required to carry out such research on the college premises.

The evidence shows that departments of chemistry have usually found it easier to provide facilities for research than have departments of engineering, and that the principal obstacle to the further development of industrial research in many technical colleges, even the largest, is lack of laboratory space. This position is attributed partly to the simpler apparatus and less space required in chemical research than in engineering research, and partly also to the absence of sufficient workshop staff; and the Council recommends that the needs of the engineering industry should be kept in mind in allocating research demonstratorships. It also urges authorities to press forward especially with extension plans for those departments in which the standard of work shows that more research could be undertaken successfully in co-operation with industry. Commenting on the circumstances in which staff should be given relief from teaching duties, the Council sees no objection to lecturers undertaking consulting work, and would support *ad hoc* investigations in colleges by members of the staff which are not of the kind that normally lead to publication; it also stresses the importance of personal relations between the colleges and industry.

THE AMERICAN PHYSICAL SOCIETY

REPORT FOR 1953

THE 1954 annual meeting of the American Physical Society was held at Columbia University, New York City, during January 28–30, and the twenty-third annual meeting of the American Association of Physics Teachers was held simultaneously at Columbia University, Barnard College, and the City College of New York. At the joint ceremonial session of the two bodies on January 29, the retiring presidential address of the American Physical Society was delivered by Prof. E. Fermi, of the University of Chicago, who spoke on "What can we Learn with High-energy Accelerators?" The 1953 Oersted Medal of the American Association of Physics Teachers was presented to Prof. C. N. Wall, of the University of Minnesota (*Amer. J. Phys.*, **22**, 363; 1954). The twelfth Richtmyer Memorial Lecture was delivered by Prof. J. A. Wheeler, of Princeton University, who took as his subject "Fields and Particles". At the joint banquet which followed, the after-dinner speakers were Prof. Grayson Kirk, president of Columbia University, who discussed the position of physics in the social structure, Prof. Leon Brillouin, of International Business Machines Corporation, who spoke of Prof. H. A. Lorentz, and Prof. S. A. Korff, of New York University, who referred to the International Geophysical Year and recounted some of his experiences in a high-altitude laboratory in northern Alaska. The second O. E. Buckley Solid-State Physics Prize was presented to Dr. J. Bardeen, of the University of Illinois, for his outstanding contributions to semiconductor research.

At the business meeting of the Society it was reported that the total membership had reached 11,200, the financial position was satisfactory and that the *Physical Review* continued to expand. The following were elected to hold office for 1954: *President*, H. A. Bethe; *Vice-President*, R. T. Birge; *Secretary*, K. K. Darrow; and *Treasurer*, G. B. Pegram. The annual meeting was again a very large one, with a registration of 2,100 and with more than three hundred contributed papers. Columbia University, which has been host to the Society on many occasions during the past fifty years and in particular for eleven of the past twelve annual meetings, has now reluctantly admitted that such a large convention involves too great a burden, and accordingly it has been agreed to hold the 1955 annual meeting in hotels in the vicinity of Pennsylvania Station, New York City. As a valedictory to Columbia University and as a tribute, which was made doubly fitting by the fact that 1954 is the bicentennial year of the University, a special session of the annual meeting was devoted to a survey of the University's association with physics and with the American Physical Society. This consisted of four addresses and the presentation of a plaque, to be affixed to a wall in the Pupin Physics Laboratories, commemorating the Society's inaugural meeting on May 20, 1899, at Columbia University. Prof. G. B. Pegram reviewed the early years in the history of physics at the University, Prof. E. Fermi the genesis of the nuclear-energy project, Prof. I. I. Rabi the more recent years, and Dr. K. K. Darrow, the Society's secretary, discussed the link between the Society and the University.

The scientific programme of the Physical Society meeting, details of which together with abstracts of the contributed papers are given in the minutes of the meeting (*Phys. Rev.*, **94**, 742; 1954), included a joint session of the Division of Fluid Dynamics and the Institute of the Aeronautical Sciences, at which four papers dealing with high-speed flow phenomena were read; four symposia; a group of four papers in which plans for accelerators of the future, including the designs of the 25-BeV. proton synchrotron for CERN and a 15-BeV. accelerator, were discussed by E. D. Courant, J. P. Blewett, M. S. Livingston and H. G. White; and nineteen invited papers. At the Brookhaven–Nevis symposium the subjects of discussion were the use of the cosmotron as a research tool and the interpretation of high-energy experiments; at the symposium of the Division of Fluid Dynamics there were four papers dealing with aspects of shock waves in liquids and solids; at the symposium of the Division of Electron Physics the conduction mechanism, interface compound formation and noise mechanisms in oxide-coated cathodes together with a review of electronic processes in barium oxide crystals were considered; and at the separate symposium devoted to the subject of nuclear size and density of distribution four different methods of determination were described. Of the invited papers, two, by members of the Bell Telephone Laboratories, dealt with the theory of secondary electrons; two, including a discussion by J. R. Zacharias of precision measurements, with molecular beams; two with the neutrino; three, "Microwave Resonance in Colour Centres", by E. E. Schneider, of the University of Durham, "Polarization of Nuclei in Metals by Magnetic Resonance", by A. W. Overhauser, and "The Solid-State Cyclotron", by C. Kittel, with magnetic resonance; and two with cryogenics. In addition, P. W. Bridgman spoke of the effects of pressure on twelve rare-earth metals, W. A. Pomerantz on cosmic radiation at very high altitudes near the geomagnetic equator, and E. W. Corson on the properties of new V-particles.

The programme of the meeting of the American Association of Physics Teachers (*Amer. J. Phys.*, **22**, 426; 1954) consisted of two panel and one round-table discussions, three invited papers, twenty-seven contributed papers, a film session and a business meeting in addition to the joint sessions with the Physical Society. C. N. Hoyler, of the Radio Corporation of America, gave a demonstration of colour television in which recent developments of the R.C.A. were described and illustrated. In the panel discussion on "Research Subsidies and College Teaching", various problems involved in combining teaching and research were considered; and in the session devoted to a discussion of the functions and mission of the Association, H. K. Schilling reviewed the history of the Association and T. H. Osgood, editor of the *American Journal of Physics*, spoke on "What goes into the Journal". At the business meeting of the Association on January 30, it was agreed to confer honorary membership on D. Bronk, former president of Johns Hopkins University, president of the National Research Council and head of the Rockefeller Institute for Medical Research; and for noteworthy service to the Association T. D. Cope, P. Kirkpatrick, C. J. Overbeck and M. H. Trytten were voted special citations. The need for increased income to cover current expenses was emphasized and a change in the by-laws was approved to permit the increase of subscriptions to a maximum of eight dollars per annum. The following were elected to hold office for 1954: *President*, P. M. Marsh; *President-elect*, R. R. Palmer; *Treasurer*, F. W. Sears; and *Secretary*, R. F. Paton.

BREEDING FOR BEEF IN TROPICAL AND SUB-TROPICAL CLIMATES

CLIMATE, and temperature in particular, is directly concerned with the success or failure of animal production in tropical and sub-tropical territories. It has been established in various parts of the world that wide variations exist between different breeds and types of farm animals in their ability to adapt themselves to the climatic conditions peculiar to a particular environment. Because of their low powers of adaptability, the introduction of European breeds has failed in most tropical territories, and this has focused the attention of research workers on the wide range of ecological problems confronting the livestock industry in those parts of the world (D. M. Joubert, *Colonial Plant and Animal Products*, **4**, No. 1; 1954).

In the breeding of livestock for tropical and sub-tropical environments, it is important to pay attention to the conformational features and breed characteristics which promote adaptability. First, for maximum radiation to be possible, the animal must possess a large skin area. It is a noticeable feature of cattle native to tropical regions that they have a well-developed dewlap which extends down to the navel, together with easily extensible skin folds which are especially numerous in the neck and thoracic regions. These characters are illustrated in the Afrikaner bull and cow, a tropical breed indigenous to South Africa and belonging to the lateral-horned zebu group. In the zebu cattle of India the ears, too, are considerably larger than those of *Bos taurus* (European) cattle.

Hair covering, which includes the thickness of the coat and structure of the hair fibre, is of equal importance in heat regulation. The critical temperature of smooth-coated cattle lies several degrees below that of woolly-coated individuals. In recent investigations, Bonsma and his associates have showed that, with the progeny of a mutant woolly-coated Afrikaner bull, tropical degeneration is possible also in the native stock should they lack any of the essential attributes which promote adaptability.

Earlier studies showed that a light-coloured coat is superior to black in the dry tropics. White or cream-coloured individuals do even better than reds provided that the hide is protected by pigmentation. Colour is regarded as playing a part in heat regulation by influencing the amount of sunlight that is reflected from the skin. Dark colours presumably tend to increase the heat load of the animal. Measurements of the reflexion of light from various coat colours indicate that the coat of white Afrikaners absorbs about 45 per cent of the solar radiation impinging upon it, as against 89 per cent in the case of the black hairy coat of Aberdeen-Angus cattle, 78 per cent of red Afrikaners, 93 per cent of red Sussex cattle and 50 per cent of cream-coloured Simmenthalers.

The effect of a tropical environment on the conformation of an unadapted beast is shown by comparing an unadapted woolly-coated Shorthorn cow with a normal individual of similar breeding and age. Whereas the beef Shorthorn is normally a digestive type—that is, relatively round in cross-section and equally deep through both chest and belly—the exotic animal in tropical environments tends to develop into a respiratory type. This may be explained by the fact that the Shorthorn has a limited skin area and also a woolly coat, both lowering its capacity of heat loss. The burden of thermolysis thus falls almost entirely on the water-evaporating capacity of the lungs, and the obvious conformational change to take place is an increased lateral depth of chest, flattening of ribs and a contracted belly.

Joubert has also considered the effects of the nutritional environment on cattle in tropical countries. In regions with fluctuations in the nutritive value of the natural pastures, as well as with high summer temperatures, the problem of adapting the exotic beast is complicated. As the body temperature increases during the hot months, metabolism is stepped up, the time spent in grazing is reduced and that of lying in the shade increased. In short, the animal suffers from a constant fever or hyperthermia. If the grazing is exceptionally poor, it is quite impossible for the leeway to be made up during the period of the year when temperate cattle are not affected by the climatic conditions. In the case of the animal surviving, it virtually exists in a state of chronic undernourishment.

Although animal breeding still presents many problems, both genetical and physiological, the knowledge gained from scientific approaches to the subject during the past three decades has made it considerably more exact and practicable. Scientific investigations provide the evidence to prove that the high-grade European breeds of cattle, which are the result of selection for maximum performance under temperate climatic conditions, do not maintain the same qualities when transferred beyond the borders of their natural habitat or of regions with approximately similar conditions. Hence, improvement of animal production by merely replacing the cattle native to tropical and sub-tropical regions with highly improved breeds of temperate origin is out of the question.

The genetical variation occurring within the exotic breeds makes possible the selection of individuals possessing those attributes required for increased adaptability to tropical conditions. By basing their selection on such characters as coat covering and colour, Bonsma and his associates have achieved considerable success in increasing the heat tolerance of British beef breeds, especially Herefords, at the Mara Research Station, which is situated in the dry-tropical zone of South Africa. The limit of such a policy is indicated, however, by the fact that when these investigations were repeated at the Messina Experimental Farm, situated in a lower-lying tropical belt, they met with complete failure. The high mortality-rate of the British beef breeds in the tropics, compared with the indigenous stock, also seriously limits the value of breeding adapted strains of European cattle.

Cross-breeding between the indigenous stock and exotic types presents a second possibility. During the early stages of livestock improvement in tropical regions, a policy of grading up with European breed bulls was advocated. The first generation cross-breds excelled because of hybrid vigour and the genetical dominance of heat-tolerant characters; as the percentage of indigenous blood diminished in subsequent generations, the cross-breds also deteriorated.

The most constructive and successful of all long-term policies for livestock breeding in tropical and sub-tropical regions seems to lie in improvement of the indigenous stock by means of judicious selection. The high standard of animal production of temperate countries can never be attained in tropical regions, while the indigenous stock of the tropics are inherently of lower productivity than their cousins of the temperate zone. Nevertheless, in the Afrikaner, it has been demonstrated that improvement of beef qualities is possible without any loss of those characters which give the breed superiority over exotic types in the tropics and sub-tropics. As for its slower growth and maturing characters, these actually are inherent qualities of practical significance and value in the production of beef under varying conditions of climate, and especially nutrition. As a result of a slower growth-rate, the influence of periodic nutritional depressions is not so acute as is the case with the rapidly growing, early-maturing breeds of beef cattle.

LIBRARY CO-OPERATION IN BRITAIN

THE final recommendations on Library Co-operation of the Joint Working Party set up by the National Central Library and the National Committee on Regional Library Co-operation have now been issued in the name of the Library and the National Committee*. The working party was satisfied that the general structure of library co-operation and inter-lending is sound, and recommended that university and special libraries outside the area covered by the London Union Catalogue and the South Eastern Region should become participant members of their appropriate regional system on the basis on which many of them at present co-operate, and that they should also retain the existing right to send applications direct to the National Central Library. Within this area, however, it recommends that, as at present, university libraries should apply direct to the National Central Library for inter-library loans, but special libraries should have direct relations with the Central Library; and that membership of the London and South Eastern Regional Library systems should remain restricted to the public library authorities within the area.

The working party is also satisfied that the Union Catalogue is necessary for effective inter-lending, and recommends that the existing Union Catalogue should be brought up to date. The Yorkshire, North Western and West Midland Regions should consider how best they may provide Union Catalogues of stock prior to a specified date, which would be adequate for regional and national purposes, and from that date all regional union catalogues should contain entries for British books, and for all other books published outside Great Britain, and those published in Great Britain prior to the specified date. The working party also recommends that each region should consider what co-operative arrangements could be made to ensure that all applications to the bureaux for current British material are supplied from resources within the region, and to ensure that at least one copy of every non-fiction book in the region is retained permanently in that region. Each region should also investigate the methods by which the range of periodicals can be improved and their permanent preservation ensured.

The working party recommends the exclusion from the scope of all inter-lending agencies of: (*a*) those works of English and American fiction outside the scope of the joint fiction reserves to be set up in the various regions; (*b*) sets of copies of plays for acting and reading outside the scope of any joint play collections to be set up in the regions; (*c*) children's books; (*d*) 'quick reference' books (that is, dictionaries, atlases, encyclopædias, etc., likely to be regularly consulted in a library); (*e*) current year-books, annuals and directories; (*f*) current numbers of periodicals.

It also suggests that all books in print costing 25*s*. or less should be outside the scope of the National Central Library.

The working party considers that any long-term plans for bringing these regional bureaux to a state of greater efficiency and maintaining them adequately should attract a grant from H.M. Treasury. It is indicated that the National Central Library proposes to institute, in consultation with the National Institute of Adult Education and the other bodies concerned, an inquiry into the present provision of books for adult education classes, with the view of considering how far the type and the extent of the services require modification.

THE FILM AND THE SOCIAL SCIENCES

ALTHOUGH film processes are being increasingly used for research in the physical and biological sciences, little attention is paid to the cinema as a medium for investigating, teaching and propagating new knowledge in the social sciences (*Science and Film*, 3, No. 2; June 1954). This may perhaps arise from an old-fashioned but not entirely played-out attitude of disdain for the place to be given, within the hierarchy of knowledge, to the study of human relations and human behaviour. An over-narrow view of the film-medium itself may also at times colour our outlook on its applications to science. The camera has, of course, special qualities for the observation of time and of mechanical movement, and the roles it can fulfil in the 'exact' sciences are obvious. But its usefulness does not end there.

The camera as an instrument of research in the social sciences has so far been little developed. Even for investigating manipulative processes, of such demonstrable value to the study of workshop skills and of industrial conditions generally, its use still remains the exception rather than the rule. For more subtle and less tractable problems of human behaviour, its use has been even less explored. Two recent examples of the use of the camera in psychological inquiry—of maternal separation and of the reactions of children to the cinema—illustrate well some of the possibilities. A rather similar, though brief, use of the motion-picture camera occurred in "Children Learning by Experience", itself a remarkable 'anthology' of children's behaviour as an aid in the training of teachers. Less normal phenomena form the subject of a pioneer Canadian series of filmed case-histories for the use of psychopathologists. Here the camera records permanently, unobtrusively and 'objectively'. To take another branch of the social sciences, no subject offers perhaps so wide a scope for the film record as does anthropology. Among many instances, Dr. Mountford's "Tjurunga" and his other films of the Australian stone-age men reflect the interest, not only scientific but also sometimes æsthetic, of such visual reports. Indeed, the trained cinematographer might well be considered an indispensable member of all field-teams engaged in anthropological or ethnological studies.

The dramatic qualities of the film medium are also available to the social scientist for explaining his purposes and methods to the general public. The cinema can illumine, too, the social relations of science; and this is perhaps one of the most important of its functions. There is need for films which will explain to the man in the street what science is, how scientists think and work, and the limits and freedoms affecting their activities. To this task the cinema as an art can bring special qualities of imagination and human warmth.

RESEARCH COUNCIL OF ALBERTA

REPORT FOR 1953

THE thirty-fourth annual report of the Research Council of Alberta, to which are appended lists of committees, staff and publications, covers the calendar year 1953* and emphasizes a shift in emphasis in coal research towards the exploration of the chemical potentialities of coal. Besides this a palæobotanical study was made of the flora and biological origin of Alberta coal measures, as well as investigations into the chemical and colloidal structure of coals. The vertical electric tube furnace for the determination of volatile matter in coal, built in 1929, was redesigned and a 14-in. rotating, self-clearing grate and ancillary control and recording equipment, installed in 1952, was used to complete an evaluation of the combustion characteristics of typical Alberta coals; a study of water retention by coal was also completed. Investigation of the trace metals in oil-sands oil and other Alberta oils suggests that occurrence of vanadium and nickel may serve as a precise correlative for crude oils and that cretaceous oils in general have a common origin. Attention is being directed to the origin of the trace-metal carriers, the porphyrins, and studies are proceeding on the properties of the heavy oils of Alberta and the viscosity of dispersions of wet oil containing mineral matter. The survey of the quality of Alberta gasoline continued, further tests were made on the storage of aviation gasoline, and work also continued on the partial oxidation of butane, in which a new reaction system was designed and built, and on the production of carbon black in a tubular furnace.

Field work by the Geological Section included detailed studies of selected areas for uranium in north-eastern Alberta, along the north shore of Lake Athabasca, and in the north-central portion of the Pre-Cambrian outcrop area in Alberta and especially north of Fidler Point and Leggo Lake, as well as a Pleistocene study in east-central Alberta. A fundamental mineralogical investigation of montmorillonite, the chief constituent of bentonite, in which forty samples of montmorillonite were subjected to X-ray and differential thermal analysis, indicates that every montmorillonite is a complex and intimate mixture. Further work under the Highway Research Project indicates that the dispersing and other properties of lignosol are important factors, as well as the viscosity effects, in preventing the migration of soil moisture to the frost line, and that sodium hexametaphosphate is equally effective in preventing frost action. Soil surveys were concentrated largely in the Peace River area, and a reconnaissance survey of the Grande Prairie sheet completed the field work on some 750,000 acres. Irrigation research was commenced on the solonetzic soils of the projected Red Deer irrigation area to determine the response to irrigation of various methods of treatment.

In the Industrial Projects Section research and testing for industry are of increasing importance. The ten-year biological cycle now appears to have reached the collapse predicted, and various publications on these extensive investigations are now being prepared. Two other investigations in animal science related to the effect of 'management factors' on the percentage hatch of turkey eggs and to the nutritive value of varying types of grass silage. A committee was appointed to study the fluoridization of municipal water-supplies. Routine measurements of solar ultra-violet radiation continued.

FREE NERVE ENDINGS AS TRANSDUCERS OF THERMAL STIMULI

By H. J. V. TYRRELL
Department of Chemistry, University of Sheffield
and D. A. TAYLOR and C. M. WILLIAMS
Department of Anatomy, University of Oxford

RECENT evidence suggests that the encapsulated nerve endings postulated by von Frey to subserve specifically the sensations of warmth and cold (Ruffini corpuscles and Krause end bulbs, respectively) are not related to thermal sensibility, for, among other things, thermal sensations are as easily evoked from regions devoid of them as from regions where such encapsulated endings occur[1-3]. Moreover, it has now been shown[4] that thermal sensations can be aroused from the cornea, a tissue devoid of blood vessels and innervated solely by nerves the terminals of which are unencapsulated (free). In normal hairy skin, which is not being subjected to deformation, there is evidence which suggests that free nerve endings do not give rise to propagated action potentials under isothermal conditions; they only discharge when thermal gradients occur in the skin in which they lie[5]. In support of this, Hodgkin and Katz[6] have shown that under isothermal conditions the resting potential of the giant squid axon is practically constant (the mean value being 47 mV.) between −1° C. and 20° C. It is also known[7,8] that a burst of propagated action potentials is evoked when a nerve trunk is heated or cooled relative to an adjacent region.

The mechanism by which a free nerve ending gives rise to a propagated disturbance when conditions are not isothermal has been compared[9] to the principle upon which a thermopile type of bolometer gives rise to an electromotive force. This analogy, though useful, must eventually be capable of expression in terms of the ionic hypothesis if the mechanism postulated is to be validated. What follows is an attempt to explain the discharge of propagated disturbances by free nerve endings under non-isothermal conditions.

A difference in temperature between the two junctions in a metallic thermocouple gives rise to a thermo-electric potential. This has two components: (1) due to the difference in potentials at the two metal–metal interfaces (Peltier e.m.f.), and (2) due to the difference in potentials in the two homogeneous metal conductors due to the temperature gradient (Thomson e.m.f.). Depending upon the metals used, the Peltier e.m.f. is ten to a hundred times greater in magnitude than the Thomson e.m.f. The free nerve terminals are less than 1 micron in diameter. Since the light microscope cannot resolve boundaries in objects so small, it is not known whether an axoplasmic filament is in fact a homogeneous medium in equilibrium with the extracellular fluid or whether it is a miniature of the axon with two interfaces, for example, extracellular fluid/membrane/axoplasm[9]. It is likely that the effects which are postulated below will occur in either case, but for the sake of brevity it is assumed that the nerve terminal can be regarded as a medium in which ions are adsorbed in equilibrium with extracellular fluid containing free ions. A phase boundary potential will exist at the interface, and if a portion of the interface is heated or cooled with reference to another portion, a potential difference consisting of the following components will be set up in the system:

(1) The difference in the interface potentials at the two temperatures. This is analogous to the Peltier e.m.f.

(2) The thermal diffusion potentials in the extracellular fluid and in the nerve terminal due to the temperature gradient. This is analogous to the Thomson e.m.f.

The effect of the thermal diffusion potential in the extracellular fluid can be estimated approximately, since the initial thermal diffusion potential in solution before the Soret equilibrium is established is given by:

$$-\sum_{i} \frac{t_i Q^*_i}{z_i F T},$$

where t_i, z_i and Q^*_i are the transference number, valency and heat of transfer respectively of the ith ion and the summation is taken over all ions in the solution[10]. For extracellular fluid in the giant squid axon this potential may be calculated (on the assumption that all ionic heats of transfer are equal to 1 kilocal./mol.) to be about 40 microvolts per degree. This e.m.f. would not be enough to cause the discharge of a giant squid axon. It is known that the capacity of a nerve membrane[11] is of the order of 1 microfarad. cm.$^{-2}$. A change of potential of 1 mV. across such a capacity requires a charge transfer of 10^{-9} coulomb cm.$^{-2}$, or approximately 10^{-14} gm. equivalents cm.$^{-2}$ of a univalent ion. This is a small fraction of the amount of any diffusible ion transferred per second across the membrane (10^{-10} to 10^{-12} gm. equivalents cm.$^{-2}$, ref. 12). Clearly a local potential change of a magnitude greater than a thermal diffusion potential in a homogeneous phase would be produced across the membrane if the diffusion-rate of any one ion was affected, even to a relatively small degree, by a change in temperature. In this connexion, it is of great interest to note that Hodgkin and Keynes have recently observed that the activity of the 'sodium pump' in extruding sodium ions from the surface of the membrane of the giant squid axon has a high temperature coefficient[13]. It is therefore not unreasonable to assume that for a free nerve terminal in contact with extracellular fluid, the major contribution to the thermal e.m.f. would also arise at the interface between the phases. In this case there would be an exact analogy with a metallic thermocouple, the electrons of the latter being replaced by ions common to both phases. The existence of such a thermopotential would provide a stimulus to nerve terminals identical with that provided by the passage of a d.c. current across the nerve[14]. The sign of the potential will depend upon whether the tip of the fibre is heated or cooled with respect to the parent axon. The local ionic currents will change in direction accordingly; however, in either event, the nerve may discharge, being 'triggered' either at the tip of the fibre or near the stem axon. There is no need, therefore, to postulate different mechanisms to account for the response of free nerve endings to 'warm' and 'cold' stimuli. The spontaneous activity of end-organs in the ampullæ of Lorenzini[15] and the spontaneous activity of thermal receptors in the tongue of the cat[16] are explicable on the basis of non-isothermal conditions across the nerve terminals involved.

An attempt to measure this effect was made by Bernhard and Granit[7]. They neglected, however, to ensure that both their test electrodes were at the same temperature. Hence, the measured potentials included the variation in potential of the electrode system with temperature. This phenomenon is well known[17-19]. Experiments have shown that the temperature coefficient of the e.m.f. of the cell,

$$\underset{T}{\text{Ag—AgCl}} \mid 0{\cdot}9\%\ \text{NaCl} \mid \underset{T + \Delta T}{\text{Ag—AgCl}},$$

is 400 microvolts per degree (heated electrode positive), which is comparable with the value obtained by Bernhard and Granit in their system, which included a nerve fibre.

Any experiment to detect thermo-electric potentials in nerve must be so arranged as to exclude this electrode effect by keeping the electrodes at the same temperature. In any such experiment it is impossible to avoid thermal diffusion potentials in the salt bridges or other devices used, but these effects are certainly much smaller than potential changes at the electrodes if they are not kept at the same temperature. BIOLOGICAL ROLE OF DEOXYRIBONUCLEIC ACID

By DR. ALFRED MARSHAK and CELIA MARSHAK

Marine Biological Laboratory, Woods Hole, Mass., and Lerner Marine Laboratory, Bimini, Bahamas

ACCORDING to the most widely accepted theory, deoxyribonucleic acid or deoxyribonucleic acid-protein is the primary genetic material and functions by acting as a template. Another theory has been proposed which postulates that ribonucleic acid-protein is the primary genetic material, specificity at each genetic locus being determined by different types or proportions of ribonucleotides and polyribonucleotides released by the ribonucleic acid-protein at that locus, alleles representing conditions at a locus that result in different rates of release of nucleotides[1]. The former hypothesis requires among other things that deoxyribonucleic acid be continually present in the nucleus and chromosomes. Some previous observations[2,3], together with results that will be briefly presented here, indicate that it is absent from the pronuclei of some echinoderm eggs. If these observations are correct, they would invalidate the deoxyribonucleic acid – template theory, but would offer no cause for embarrassment of the hypothesis that ribonucleoproteins are primary genetic materials.

The pronuclei of the eggs of *Asterias forbesii* and *Arbacia punctulata* have been shown to give a Feulgen-negative reaction which could not be attributed to dispersion of the deoxyribonucleic acid in an unusually large nuclear volume[2,3]. In a suspension of mature *Arbacia* eggs it was possible to account for the deoxyribonucleic acid found by isotope dilution analysis with ^{14}C-thymine as being contained in contaminating somatic cells[3], the polar bodies, and the egg cytoplasm. A similar but more precise analysis has been carried out on a preparation of mature eggs of the sea urchin *Tripneustes ventricosus*.

The specific activity of the thymine added was 4,020 counts per minute per microgram and of that recovered 1,389, with maximum deviations of 1·16 per cent and 1·57 per cent respectively for triplicate aliquots assayed. Agreement of the absorption spectrum of the recovered thymine with that of pure thymine was better than 1 per cent. The amount of thymine found in the preparation, which contained $1{\cdot}435 \pm 0{\cdot}50 \times 10^{6}$ eggs, was 68·18 μgm. The proportion of contaminating somatic nuclei to eggs in the preparation was $0{\cdot}512 \pm 0{\cdot}016$. Analyses on sperm of the same species gave the amount of thymine per sperm as $12{\cdot}14 \pm 0{\cdot}15 \times 10^{-6}$ μgm. Making the assumption, which appears to be justified by various reports in the literature, that each somatic nucleus contained twice the amount of deoxyribonucleic acid found in the sperm, the amount of thymine which could be assigned to the contaminating somatic nuclei was 17·85 μgm. The remainder was equivalent to $35{\cdot}07 \times 10^{-6}$ μgm. of thymine attributable to each egg and its polar bodies. This quantity was 2·89 times the amount of thymine per sperm, or almost exactly the amount expected in the polar bodies alone if each contained the haploid quantity of deoxyribonucleic acid. Alternative assignment of the thymine equally to all members of the meiotic tetrad resulted in each having only 70 per cent of the amount found in sperm. The 30 per cent deficiency is 32 times the standard error of the determinations and therefore quite unlikely to occur by chance. Such equal distribution was not justified by the cytological observations, which showed that the polar body nuclei were Feulgen-positive, whereas the egg pronucleus was Feulgen-negative. Thus within the limits of error of the determinations, there appeared to be no deoxyribonucleic acid-thymine and hence no deoxyribonucleic acid in the eggs themselves. The possibility that the deoxyribonucleic acid of sperm and of immature oocytes would contain thymine, while that of a hypothetical deoxyribonucleic acid in the mature egg would not, was rejected as highly improbable.

Mature eggs of *Arbacia* were centrifuged at 78,000 *g* for 30 min. and then treated by the Feulgen procedure after fixation. No aggregates of Feulgen-positive material could be found in the nuclei of these eggs as had been reported by Brachet for eggs in the germinal vesicle stage[4]. By direct analysis of isolated nuclei of *Asterias* eggs in the germinal vesicle stage, the deoxyribonucleic acid content per nucleus was found to be 6·2 times that of sperm of the same species. In the three species investigated, both staining procedures and chemical analysis revealed an abundance of deoxyribonucleic acid in the nuclei of young oocytes, although no clear evidence could be found for its presence in the pronuclei of the mature eggs of the same species.

Since these eggs can be induced to develop parthenogenetically, absence of deoxyribonucleic acid from their nuclei would argue against the theory that this acid is the primary genic material in the sense that it is the initiator of gene reactions. However, a regulatory role for deoxyribonucleic acid would not be so excluded. In the hypothesis mentioned previously, it was proposed that deoxyribonucleic acid had such a function. Structural similarity between ribonucleic and deoxyribonucleic acid is suggested by the observations that deoxyribonuclease (or depolymerized deoxyribonucleic acid) will reduce the rate of removal of ribonucleic acid nucleotides from nuclei by ribonuclease[5], and that after removal of its purines, deoxyribonucleic acid is digested by ribonuclease[6]. With sufficient structural homology in the two types of nucleic acids, competition between them in cellular reactions may be assumed to be probable, as is indeed suggested by the first of the observations mentioned above. Furthermore, since the rate of turnover of ribonucleic acid *in vivo* is known to be rapid, whereas that of deoxyribonucleic acid is very slow, it follows that where such competition exists, the latter will act as an inhibitor of the former. The hypothesis may be generalized to include similar inhibitory action of deoxyribonucleic acid derivatives toward analogous ribose compounds. Support for this generalization may be found in Carter's finding of inhibition of mitochondrial oxygen consumption by deoxyriboside-5′-phosphate, which is overcome by adenine ribose phosphate[7].

The hypothesis will satisfactorily account for a variety of biological observations, involving nucleic acids such as the *Ds—Ac* modifiers of *Zea*[8], maternal influence in inheritance in mammals and somatic influence on pollen in plants[9,10], the behaviour of bacterial transforming substances[11,12], and of provirus[13]. Its usefulness becomes especially apparent in providing an interpretation of turnover studies on bacteriophage[14] and behaviour of interspecific hybrids in the genus *Rana*[15], for which no adequate explanation has been found in terms of other current theories. In the case of bacteriophage, it has been shown that synthesis of new deoxyribonucleic acid after infection occurs in excess of and in advance of the need for actual incorporation into the new phage particles[14]. The deoxyribonucleic acid synthesized before any new phage particles are formed is approximately equal to the amount originally present in the bacterium—that is, in terms of the present theory, an amount which is sufficient for the antagonism of the genic apparatus of the bacterium. As described by Brachet, the hybrid *Rana* embryos ordinarily cease to develop at the end of the blastula stage, at which time the amount of nuclear deoxyribonucleic acid they contain is markedly diminished, ribonucleic acid turnover is enhanced, while oxidations are diminished as compared with the normal. Since transplantation of the blastopore lip to a normal embryo will permit continued growth and development, diffusible substances seem to be involved[15]. In terms of the present hypothesis, the following interpretation of the observations is possible. The deficiency in deoxyribonucleic acid suggests the release of unusual amounts of its derivatives to the cytoplasm, with the result that oxidations will be reduced by blocking of the ribonucleotides involved, and since a good portion of the deoxyribonucleotide has been removed, the nuclear ribonucleic acid which is normally more reactive than that of the cytoplasm will be capable of more rapid turnover than normal. Growth after transplantation becomes possible by diffusion into the transplant of ribose compounds of the host, or by removal of excess deoxyribose compounds of the transplant into the host.

A full account of the experimental details and of the hypothesis will be presented elsewhere. This investigation was supported by a grant from the Division of Biology and Medicine of the United States Atomic Energy Commission. [June 27.

DIFFERENTIATION OF GROWING AND NON-GROWING BACTERIA BY A STAINING TECHNIQUE

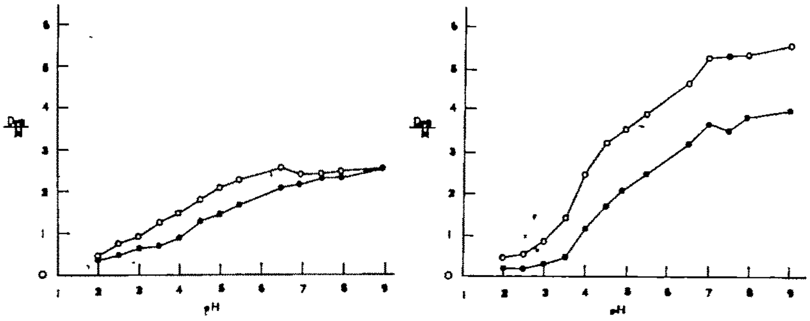
By H. E. WADE and D. M. MORGAN

Microbiological Research Department, Experimental Station, Porton, Wilts

It has been known for some years that growing bacteria are more strongly basophilic than non-growing bacteria. In *E. coli* this difference has been attributed to the presence of unbound ribonucleic acid in growing bacteria[1]. That ribonucleic acid is responsible in all bacterial species is improbable in view of the presence in some of inorganic polyphosphates[2] the abundance of which appears to vary like ribonucleic acid with the physiological condition of the bacterium. In order to supplement other evidence for the presence of unbound ribonucleic acid and to seek a convenient microscopic means of assessing the abundance of this constituent in *E. coli* (*N.C.T.C.* No. 1100) the affinity of this bacterium for the weakly basic dye toluidine blue was investigated.

It became evident that, by an initial acid extraction of the bacteria and by the application of the dye at a pH which would reduce interference from protein to a minimum, a staining technique, applicable to all the bacteria tested (including Gram-positive bacteria), could be obtained by which growing cells alone showed marked basophilia.

A quantitative assessment of the basophilia of growing bacteria, taken from an aerated casein/casein/



(A) (B)

Fig. 1, *A*. Absorption of toluidine blue by non-growing and growing *E. coli* bacteria; *B*. Absorption of toluidine blue by acid-extracted non-growing and growing *E. coli* bacteria. —●—●—, non-growing bacteria; —○—○—, growing bacteria. The basophilia is expressed as weight of dye absorbed/weight of bacterial nitrogen

yeast[3] culture during the period of maximum growth and division-rates, and non-growing but viable bacteria, taken from the culture when growth had ceased, was obtained by suspending the washed bacteria in 0·2 per cent toluidine blue solution in 0·05 *M* buffer and extracting the dye absorbed with normal hydrochloric acid.

The influence of an acid extraction on the basophilia of growing and non-growing bacteria and the influence of *p*H can be seen in Figs. 1 *A* and *B*. The contrast between growing and non-growing bacteria is optimal in acid-extracted bacteria at *p*H 3·5; the quantitative difference in dye absorption is optimal above *p*H 4·0. For the purpose of microscopical observation, however, the staining of rapidly growing cells is sufficiently intense at *p*H 3·5 for advantage to be taken of the optimal contrast afforded by this *p*H.

At *p*H 3·5 untreated growing bacteria appear to absorb approximately 80 per cent more dye than untreated non-growing bacteria; acid-extracted growing bacteria appear to absorb approximately 200 per cent more dye than acid-extracted non-growing bacteria. Under the conditions of determination, however, part of the dye measured as absorbed by the bacteria is derived from dye passively contained in the bacteria and dye present in solution retained with the bacteria after centrifugation. This accounts for the fact that the assessment of basophilia by microscopic observation of stained bacteria suggests a far greater contrast between acid-extracted growing and non-growing bacteria than expected from the measurements made. Fig. 2 shows an artificial mixture of acid-extracted growing and non-growing *E. coli* bacteria stained with toluidine blue in the manner described below. The very weakly basophilic non-growing cells have absorbed sufficient dye to make them just visible.

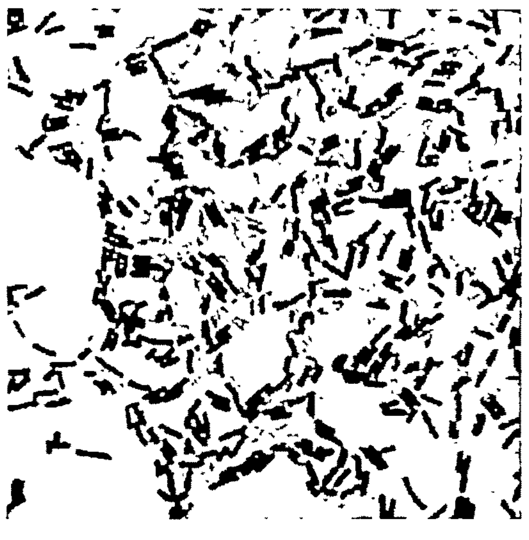


Fig. 2. An artificial mixture of acid-extracted growing and non-growing *E. coli* bacteria treated with toluidine blue at *p*H 3·5

In order to render weakly basophilic bacteria more visible and to facilitate the distinction between growing and non-growing bacteria, the staining procedure finally adopted and described below includes the use of eosin as a counter stain.

The culture was treated immediately upon reaping with sufficient concentrated hydrochloric acid to give a concentration of 0·33 *N* hydrochloric acid. The bacteria were centrifuged down, washed once in 0·33 *N* hydrochloric acid, then taken up into a little water and treated gradually with '*IR* 400' (OH) resin until the *p*H was 3·5–6·0. A loopful, applied to a slide, was air-dried and heat-fixed. The preparation was stained at 45° C. for at least 10 min. in 0·5 per cent toluidine blue made up in 0·05 *M* formate buffer at *p*H 3·5, washed for 0·5 min. with distilled water, blotted and dried. It was then stained for 30–60 min. in 0·05 *N* acetic acid saturated at room temperature with eosin (water-soluble, yellowish), washed briefly with tap water, blotted and dried. This staining procedure resulted in non-growing bacteria staining pink and growing bacteria blue-violet.

If, as is most likely, the high content of ribonucleic acid in growing Gram-negative bacteria is responsible, the intensity of the blue staining will depend upon the growth-rate after the first generation[4].

The potential use of the staining technique for assessing the viability of bacterial suspensions has been considered. For the assessment of the viability of a suspension of bacteria derived from a fully-grown culture, two methods have been entertained.

One method involves the counting of pink-staining bacteria before and after incubation of the bacteria in a medium that supports very rapid growth and for a period that allows the viable bacteria present to attain a high rate of growth and change their staining reaction. This method requires the counting of pink-staining bacteria by a ratio count to inert particles of known concentration.

Another method requires some knowledge of the behaviour of the bacteria. If the stationary phase of the bacterium when incubated in fresh medium is known, a direct assessment of the degree of viability can be obtained from a ratio count of pink-staining and blue-violet-staining bacteria after incubation for the duration of this phase.

World-wide Frequency and Time Comparisons by Means of Radio Transmissions

For many years standards of frequency have been made available to users over a wide area by means of radio transmissions, the carrier waves of which are controlled by the standard; and the frequencies of 2·5, 5, 10, 15, 20 and 25 Mc./s. have been allocated to this purpose by international agreement. Frequency standards can now be maintained in operation with a stability of a few parts in 10^9 per month, and they can be intercompared in the laboratory with a precision of ± 1 part in 10^{10}. There is, however, a loss of accuracy due to transmission, and although it has been found that ± 1 part in 10^8 can be achieved under suitable conditions, the accuracy in general is limited to about ± 2 parts in 10^7 because progressive movements of the ionospheric layers at which the waves are reflected cause a steadily increasing or decreasing path-length and a consequent Doppler-effect frequency change. In view of this limitation, an experimental transmission on 60 kc./s. was included in the United Kingdom service when this was resumed in 1950, with the call sign *MSF*. The ionospheric layer at which such low-frequency waves are reflected is known to be comparatively stable, and the ground-wave of the transmission, which is, of course, not affected by changes in the ionosphere, is received over a useful area. Results[1] obtained at the National Physical Laboratory show that this transmission can be used in the United Kingdom with an accuracy of ± 1 part in 10^9 in an observation time of a few minutes; and in spite of its low power of 10 kW., it has been received and measured at Harvard University with the same precision by a somewhat different technique in a time of about 10 min. Higher accuracies of comparison can be obtained by averaging the observations over longer periods.

The *MSF* transmissions are operated from the Post Office Radio Station at Rugby, where the powerful 16 kc./s. transmitter *GBR* is also located. The carrier wave of this transmitter is now controlled by the standard used for the *MSF* transmissions in order to facilitate measurements at great distances whenever *GBR* is in operation.

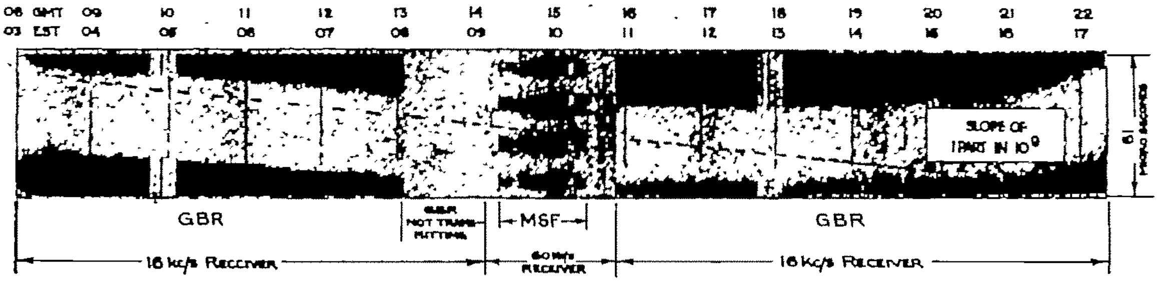

Fig. 1

A typical photographic record taken at Harvard and including the results obtained with both the 60 kc./s. and the 16 kc./s. transmissions is reproduced as Fig. 1. The edge of a dark band represents the arrival time of a particular phase of the carrier wave on a time-scale derived from the local standard; and when it forms a horizontal line the frequency of the received signal is in exact agreement with that of the local standard, or is in simple relationship with it, such as 16/100 and 60/100 in this case. The slope corresponding to a deviation from the local value of 1 part in 10^9 has been indicated in the diagram. The smoothness of the edges of the trace demonstrates that the propagation path is relatively free from short-period fluctuations, but the changes in slope are due to gradual changes in the height of the reflecting layer. Closer checking by independent means of the frequency of the local standard will enable the frequency changes associated with the diurnal movements of the layer to be accurately measured and compensated in the frequency comparisons.

These results, which will be reported more fully elsewhere, are clearly of significance in problems of frequency control, international frequency and time standardization, and navigational aids based on phase comparison; and the possibility of securing comparisons of frequency and therefore of time-interval to a precision of ± 1 part in 10^9 on a world-wide basis is probably also of interest in a much wider field. Measurements to this accuracy must at first be on a comparative basis, since the unit of astronomical time cannot be predicted with an accuracy greater than ± 1 part in 10^8; but this restriction may be removed if work on other possible units of time based on the natural resonant frequency of an atom proves to be successful.

Preparation of Aluminium of Extreme Purity by the 'Zone Fusion' Process

THE special properties of aluminium refined by double electrolysis and of conventional purity 99·99–99·998 per cent are well known. We have considered the application to this material of the 'zone fusion' process, which permits the production of germanium of extreme purity[1]. In our experiments we have employed a bar of such refined aluminium about 40 cm. long and 4 cm.^{2} in cross-section. This bar was placed in a boat of pure alumina and a length of 6–8 cm. raised to the melting point in a high-frequency furnace, the zone of fusion being traversed through the furnace at the rate of 5 mm. an hour.

In our first experiments notable purification of the 99·998 per cent metal after three such treatments was obtained[2]. After cold work, such material recrystallizes in large grains at a temperature of − 20° C.

After nine such fusion processes, the analyses being carried out with the aid of radioactive elements[3], we are led to believe that the conventional purity clearly exceeds 99·999 and is probably very near 99·9995.

By the classical strain-anneal technique we have prepared this aluminium in the form of single crystals. For this the ingot was rolled at a temperature near that of liquid nitrogen, since this metal recrystallizes at − 50° C., after which it was subjected to the usual treatment.

Measurement of the resistivities in liquid hydrogen and liquid helium[4] shows very considerable differences as compared with the refined aluminium of 99·99 and 99·998 per cent.

Fig. 1 shows the very important differences in the ratio $R_0/R_{20\cdot4°\mathrm{K}}$ (the ratio of the resistivity at ordinary temperatures to that at the low temperature) for aluminium purified by three treatments (curve 3) and nine zone fusions (curve 4).

It was important to know what proportion of the metal had been purified after nine treatments; that is, what length of the bar consisted of metal of the highest purity. In Fig. 2 we have plotted the distances from the head of the bar as abscissæ and the ratio $R_0/R_{20\cdot4°\mathrm{K}}$ as ordinates. This shows that the first 30 cm. of the bar, of total length 45 cm., consist of this highly purified material.

Such experiments demonstrate the interest which this method has for ordinary metals. The extreme degree of purity leads to new properties in many different fields, among which we are at present studying, in the laboratory at Vitry, problems of recrystallization, polygonization[5], electrical conductivity, corrosion and grain boundary fusion[2–6].

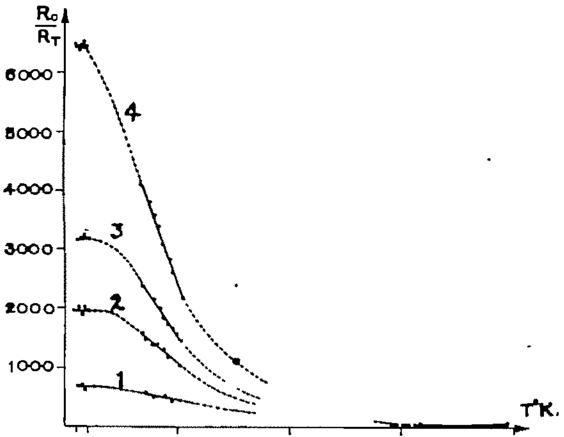

Fig. 1. Changes in the ratio R_0/R_T for different specimens. (1) 99·99 per cent aluminium; (2) 99·998 per cent aluminium; (3), as (2), after three treatments; (4), as (2), after nine treatments

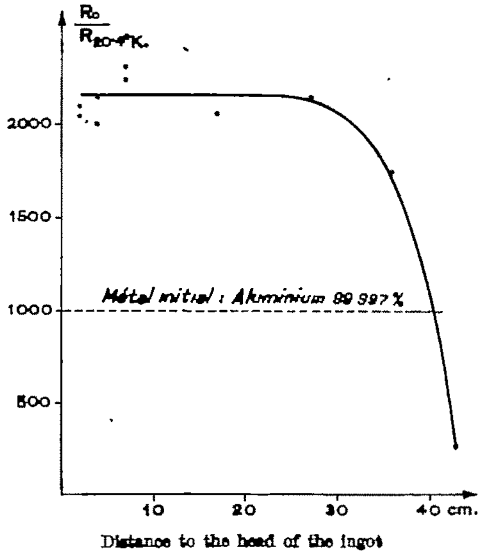

Fig. 2. Purification of 99·997 per cent aluminium after nine treatments. Note that the first 30 cm. of the bar consists of highly purified metal

Photoelastic Effects in Microscopic Fibres

THE application of fairly high pressures to fibre specimens on the microscope has been found to produce types of photoelastic stress patterns in cotton and nylon fibres. The method, which is modified from the original technique devised by Boddy[1] and that due to Merton[2], consists in applying a load to a lever system which exerts pressure on the condenser. The front lens of this is replaced with a sapphire sphere $\frac{1}{16}$ in. or $\frac{1}{8}$ in. in diameter. This operates through the cover slip on the specimen. Thus light rays can be focused through the sphere and through the material while pressure is applied or released, and the behaviour of the fibres watched throughout the process.

The interferometric slides and cover-slip of semi-metallized glass due to Merton give rise to optical path differences by reflexion, and the stress fringes in the materials may be observed without using polarizers.

Fig. 1 shows them in a cotton fibre after the pressure has been removed, and it is interesting to note that they remain in this material for some considerable time. A similar fringe system can be produced in a

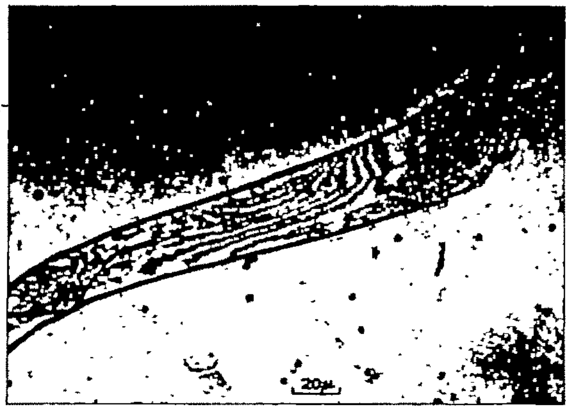

Fig. 1. Cotton fibre showing stress fringes after applying pressure

nylon fibre, where they also remain after releasing the pressure.

With collagen fibres the stress fringes also occur, but are rapidly released with the release of pressure. With cotton, two pressure impacts at different places will produce two series of fringes which may interfere like two sets of ripples on a pool.

The impact of pressure if applied suddenly results in waves of fringes which, particularly with collagen, appear to travel along the fibre axis some considerable distance before being damped.

Further work on the elastic properties of such fibres is in progress and will be reported elsewhere.

A New Approach to the Study of Electric Fields produced by Growing Roots

The electric fields primarily developed across the walls of plant cells give rise to an integrated field associated with a growing plant organ. Information from the literature with regard to such electric fields associated with plant organs is contradictory and has led to conflicting theories; and the conflict in experimental evidence has never been satisfactorily resolved. An investigation of the literature seems to us to show that artefacts developed at points where measuring probes make contact with the plant would, in most cases, swamp the normal field which it is desired to investigate.

We have made an essentially new approach by studying the currents which are generated by a plant organ in a weakly conducting medium. Potential differences are measured between points in the medium near the plant without disturbing its normal growth in any way. If these measurements are made in a suitable pattern, information about current density and direction, and the electric power developed by the plant, can be obtained. Consistent results have been obtained with bean and onion roots grown in water. As a first step in the investigation of the electrical processes associated with an organ as a whole, the changes have been observed in the pattern of electric potentials in the water which occur when growth is rapid and when it is inhibited.

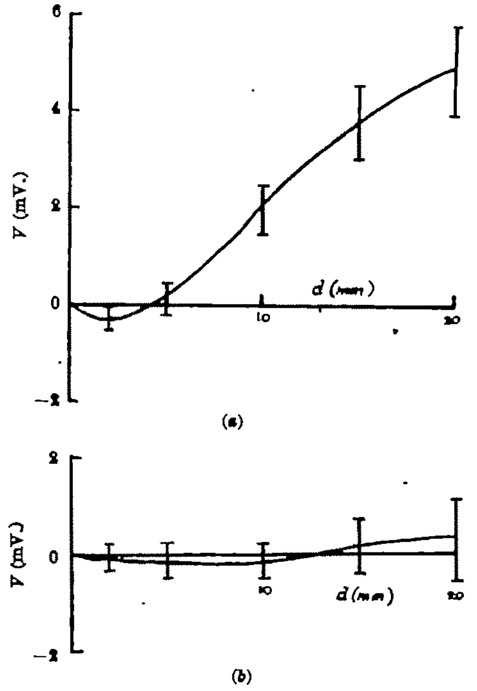

Fig. 1

Fig. 1(*a*) shows the pattern observed with bean roots growing rapidly and uniformly in aerated water at 25° C. V is the potential relative to that of the root-tip of points close to the root in the external medium (0·0001 N potassium chloride solution) and this is plotted against the distance d from the tip. The growth-rate is about 0·8 mm. per hour.

Fig. 1(*b*) shows the corresponding pattern produced when growth is inhibited. Inhibition has been produced by methods as different as the addition of indole acetic acid to the water in which the root was growing, and raising the temperature of the root. In the case of the addition of indole acetic acid, the effect was reversible, and when growth was resumed the electrical pattern returned to that associated with normal growth.

Figs. 1(*a*) and 1(*b*) show averages in experiments each of which comprised about twenty-five plants, the vertical lines through the points giving the 95 per cent confidence limits.

The electrical pattern is seldom static and shows small slow variations with time even when all environmental factors known to affect the electric field are controlled. In conditions other than that of straight rapid growth, the potential pattern may differ considerably from that discussed. In some conditions the root is observed to produce persistent and relatively rapid oscillations in its electrical pattern. These oscillations are often practically sinusoidal, with periods ranging from 4 to 15 min. or more. The more rapid oscillations are more common.

Observation of these rapid changes of electrical pattern has been made possible by the development in this laboratory of an automatic apparatus which records at frequent intervals the electric potential differences between a number of points adjacent to the root grown in water. The oscillations can be induced by experimental treatment, such as by introducing an obstacle which impedes elongation of the root, or by inducing bending by wounding. They also appear spontaneously, accompanying variations

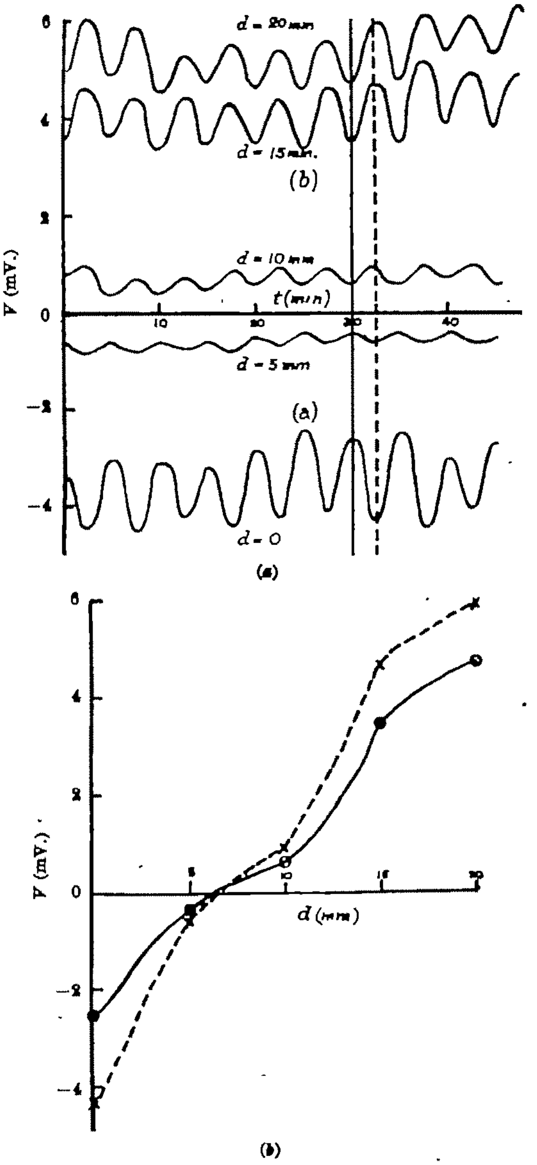

Fig. 2

in growth such as spontaneous bending. They do not occur when the root grows rapidly and evenly.

Fig. 2(*a*) shows a graph of potential against time in a typical case where electrical oscillation accompanied bending. Each trace shows the potential V relative to a distant point in the bath plotted against time t, for a point near the root at a distance d from the root-tip. The graph shows simultaneous potentials for several values of d. Note the phase differences at *a* and *b*. Fig. 2(*b*) shows the corresponding graph of potential plotted against distance from the root-tip. Two traces are shown giving potentials at times corresponding to a crest and a trough of the oscillatory potential. Where the two traces cross, the phase changes by π.

These investigations, which are part of a general study of patterns of morphogenesis, are being continued and will be described in more detail elsewhere.

5-Hydroxytryptamine : its Occurrence in Cowhage

The trichomes from the pods of *Mucuna pruriens* DC., which constitute cowhage, have long been known to cause intense itching, and some pain, when applied to the human skin. Broadbent[1] concluded, from pharmacological and histological studies, that the itching was not a mechanical effect of the trichomes but was due to the presence of a histamine-liberating substance.

In seeking to identify the active principles, we have examined a crude extract of cowhage prepared by Dr. P. Hey. 5-Hydroxytryptamine was found to be present. The concentration of the substance in the trichomes, as determined by pharmacological assay, was of the order of 0·015 per cent.

Though 5-hydroxytryptamine has been found in certain mammalian tissues and serums[2], in the gastro-intestinal and splenic extracts of fish and ascidians[3], in toad venom[4], in the salivary glands of octopods[5], and in wasp venom[6], we believe this to be the first record of its occurrence in a plant.

Armstrong *et al.*[7] have shown 5-hydroxytryptamine to be more effective than histamine as a cutaneous pain-producer in man. It is thus probable that 5-hydroxytryptamine is a factor in the causation of pain following the application of cowhage to the skin. We cannot yet say, however, whether it is the principle responsible for the sensation of itching. Further work is in progress.

An active extract of cowhage was prepared by moistening with alcohol, extracting with cold water and evaporating the aqueous extracts to dryness below 35° ; 100 gm. of the crude drug gave 10 gm. of extract. This material elicited the same type of response from guinea pig ileum and rat uterus as did 5-hydroxytryptamine (acid oxalate), and was not antagonized by atropine (5 ng./ml.) or mepyramine (50 ng./ml.)[8]. Under the same conditions the responses to acetylcholine and histamine were almost completely abolished. Lysergic acid diethylamide, at a concentration[8] of 0·1 μgm./ml., reduced the ileum responses to equi-effective doses of the crude extract and of 5-hydroxytryptamine to the same extent.

Fractionation of the original crude extract was controlled by pharmacological assay of the fractions on the guinea pig ileum. By re-extraction of the crude material with limited amounts of water, followed by chromatography of the soluble material on a powdered cellulose column using *n*-butanol/acetic acid/water (100 : 10 : 30), a fraction with 125 times the activity of the original was obtained. When this fraction was subjected to ascending chromatography on Whatman No. 1 paper, using *n*-butanol/acetic acid (10 : 1) saturated with water, 85 per cent of the total activity was concentrated in a zone corresponding to a substance with R_F = 0·42, which is the value shown by 5-hydroxytryptamine in the same system. Material eluted from this zone was also identical with 5-hydroxytryptamine in its reactions with ammoniacal silver nitrate, with diazotized sulphanilic acid, with Ehrlich's reagent, and with Jepson and Stevens's ninhydrin/acetic acid reagent[9], which last is specific for a very narrow range of tryptamine derivatives. Aqueous solutions of the most active fractions had the following light absorption : $\lambda_{\text{min.}}$ = 247 mμ, $\lambda_{\text{max.}}$ = 273 mμ, $\lambda_{\text{inf.}}$ = 300 mμ. Hamlin and Fischer[10] give the absorption of 5-hydroxytryptamine at pH 5·4 as $\lambda_{\text{min.}}$ = 250 mμ, $\lambda_{\text{max.}}$ = 275 mμ, and $\lambda_{\text{inf.}}$ = 299 mμ.

Further details of this work will be published elsewhere.

We thank Prof. B. Lythgoe and Prof. W. A. Bain for their advice and encouragement, and Mr. J. Harley-Mason for a sample of 5-hydroxytryptamine.

Perpendicular Orientations in Polyethylene

PERPENDICULAR orientation (chain-molecules perpendicular to an axis of rotation) has been frequently reported in studies on polyethylene. I have shown[1] that very similar X-ray patterns can be given by two entirely different perpendicular structures: (i) where the *a*-axis is parallel to the fibre-axis and consequently *b* and *c* are perpendicular to it; (ii) where the *b*-axis is an axis of cylindrical symmetry, and the *b*-axes themselves are randomly arranged in planes perpendicular to the direction of draw, which itself is perpendicular to the X-ray beam.

The finer details of the X-ray patterns have now been examined more closely in order to establish the existence of (i) and (ii) from X-ray evidence alone. The samples were prepared in two different ways in an attempt to produce these structures: (*a*) fully drawn and relaxed at 110° C.; (*b*) crystallized during flow while cooling from the melt[1]. The randomization of the *b*-axes in planes perpendicular to the fibre-axis in structure (ii) causes a characteristic spreading of the 200 and 110 arcs[1], as shown in the first part of Table 1. This spread could always be observed in samples (*b*).

Table 1. THEORETICAL POSITION OF MAXIMA OF SOME REFLEXIONS IN STRUCTURES (i) AND (ii) AND THEIR THEORETICAL SPREADS IN STRUCTURE (ii).
The spread given is inherent in the structure and is not due to disorientation

Reflexion	Structure (i) Maxima	Structure (ii) Maxima	Spread
110	33° from equator	34° from equator	Arc of 69° bisected by the equator
200	Meridian	Meridian	Along the whole ring
020	Equator	Equator	None
011	Equator	25–30° off meridian	The whole ring except for 44° on the meridian
201	38° off equator	Meridian	The whole ring
121	15° off equator	45–60° off equator	The whole ring except for 52° on the meridian

To obtain more conclusive X-ray evidence, reflexions other than *hk*0 were investigated, in particular, 011, 201 and 121. These are very weak, especially when drawn out in more or less extended arcs. Close comparison revealed that the patterns of samples (*a*) and (*b*) are different. Table 1 shows what is to be expected from structures (i) and (ii). The figures were obtained by the method given in ref. 1. Because of the difficulty of reproducing the photographs the effects will be described.

Reflexion 011. In samples (*a*), this reflexion was in the form of two arcs on the equator as expected from structure (i). In samples (*b*), only faint traces of the reflexion were visible on the equator, whereas there were pronounced maxima at about 25°–30° off the meridian. Caution was needed in the localization of the latter, because the 310 reflexion, corresponding to a nearly identical spacing, has maxima at a similar angle for both (i) and (ii). However, it was possible to establish that the maxima in samples (*b*) are composed of both reflexions, in agreement with structure (ii).

Reflexion 201. Here samples (*b*) gave the clearer answer, as the maxima were found to be on the meridian, as follows from (ii). With samples (*a*), the position of the maxima appeared to be at 38° from the equator, but the effect was not clear enough to be conclusive. To remove possible doubts, drawn samples were relaxed successively in small steps by exposing them to increasing temperatures from 94° to 108° C. It was found that the relaxation proceeded by a continuous tilting of the crystallites around their *b*-axes until the *c*-axes were perpendicular to the fibre direction. Also, the doubtful 201 reflexion followed the course required by this tilting until the last stage, where it merged with the 220 reflexion, its definition being further reduced by an increasing spread towards the meridian (arising from the geometry of the reciprocal lattice). These results leave no doubt about the fully relaxed samples having structure (i) as stated previously, also by other authors.

Reflexion 121. This reflexion gave the clearest evidence on the points in question. Samples (*a*) gave extended equatorial arcs consistent with structure (i) as the small split is not expected to be resolvable. With samples (*b*) the maxima were broad but clearly at about 45–60°, being connected across the equator, and having abrupt ends at about 30° off the meridian, in agreement with (ii).

These observations confirm that the samples prepared by relaxation and by crystallization under flow have basically different structures, although the principal features of their X-ray patterns are very similar.

According to private information from Holmes *et al.*, the commercial polyethylene samples used by them in their earlier work[2] have been re-examined. The positions of the relevant reflexions indicated that a few of their samples had structure (ii) and not (i) as previously published, and for the majority the X-ray evidence alone was not sufficient to distinguish between the two alternatives. In my opinion the existence of structure (ii) in commercial films is to be expected, as crystallization might occur during flow while the solidifying film is being wound up in the course of manufacture[3].

I wish to acknowledge the contribution of Dr. D. R. Holmes and Mr. R. P. Palmer, Imperial Chemical Industries, Ltd., Welwyn Garden City, whose first observations on their commercial samples initiated the present work; further, I wish to thank Dr. A. F. Wells for his interest and help.

A Simple Microtitration Method for the Determination of Calcium and Magnesium in the Hæmolymph of Insects

According to several authors[1,2], the direct titration of calcium and magnesium with ethylenediamine tetraacetate has yielded very good results, especially in the determination of water hardness and in clinical investigations of blood plasma. Since other methods described for the determination of calcium and magnesium are rather laborious, and micro-scale determination is liable to large errors, we have tried the direct titration with ethylenediamine tetraacetate using the well-known Linderstrøm-Lang micro-titration technique. Determinations have been carried out on some species of Blattaria: *Periplaneta americana*, *Periplaneta australasiae* and *Blabera fusca*.

A small amount of hæmolymph (5–20 µl.) is obtained from the insects by puncturing the ventral side of thorax or abdomen. The light yellow hæmolymph appearing on the wound is sucked up in a capillary pipette, and blown out into a small titration vessel (capacity *c.* 500 µl.) and immediately diluted with distilled water (*c.* 100 µl.). After bringing the mixture to the appropriate *p*H with sodium hydroxide and, in the case of magnesium titration, adding a buffer solution, the indicator is added and titration carried out. Murexide is used as an indicator for the presence of unchelated calcium, whereas eriochrome-black *T* is used to indicate the presence of unchelated magnesium.

As ethylenediamine tetraacetate has a much greater affinity for calcium than for magnesium, the calcium concentration may be calculated from the amount of the reagent used in the murexide titration, whereas the sum of calcium and magnesium can be found by performing an eriochrome-black titration; the magnesium concentration is therefore obtained by subtraction. Calculations are very simple since one mole of ethylenediamine tetraacetate chelates one mole of divalent cation.

The reliability of the method was tested by performing determinations of calcium and magnesium in solutions containing known amounts of calcium chloride and/or magnesium sulphate, in human sera to which known amounts of magnesium sulphate had been added, in samples from pooled hæmolymph, in samples taken successively from the same insect and in hæmolymph to which known amounts of magnesium sulphate had been added. Moreover, the results of micro-titration were compared with those of macro-titration with ethylenediamine tetraacetate and in a few cases with those of the calcium-oxalate precipitation method. The results of these checking experiments were quite satisfactory.

A large number of determinations have been carried out on hæmolymph of single individuals of *Periplaneta americana*, and some for *P. australasiae* and *Blabera fusca* (see Table 1). From these data it may be concluded that the intraspecific as well as the interspecific differences are rather small, especially in the case of calcium. Sex differences are not significant. The ratio calcium/magnesium is about the same for all three species.

Table 1

Species	Calcium* (mgm. per 100 gm. of hæmolymph)	Magnesium* (mgm. per 100 gm. of hæmolymph)	Calcium/magnesium ratio†
P. americana	(107) 17·8+1·9	(83) 13·5+3·0	0·79
P. australasiae	(17) 19·4+2·8	(20) 14·8+4·1	0·79
Blabera fusca	(7) 20·2+2·9	(3) 15·7+2·0	0·77

* Numbers in brackets indicate the number of determinations.
† Calcium and magnesium concentrations expressed in molarities.

As our purpose is to offer a reliable micro-method for the determination of low concentrations of calcium and magnesium in small amounts of biological fluids, it is interesting to compare our results with the few found in the literature. Calcium values are in full agreement with those of Clark and Craig[3]. This, however, is not the case for the magnesium determinations; Clark and Craig found 27·5 mgm. per 100 gm. of hæmolymph, Tobias[4] gives a value of only 7 mgm. per 100 gm. of hæmolymph, both for *P. americana*. In our view the dry-ashing of the hæmolymph as used by both authors may lead to erroneous results, as by this procedure organic phosphorus is converted to possibly interfering inorganic phosphates. However, differences in the animal material may also have played a part, although we do not consider this very probable.

Our experiments permit no conclusion as to the state in which the elements investigated are present.

A more detailed report of our investigations will be published elsewhere.

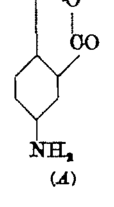
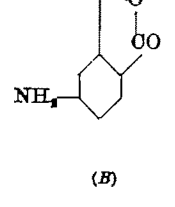
A Chromatographic Separation of the Aminofluorescein Isomers

In the preparation of aminofluorescein by the condensation of 4-nitrophthalic acid and resorcinol followed by reduction, two isomers (*A*) and (*B*) are formed at the condensation stage, and these must



(*A*)



(*B*)

be separated if unequivocal results are to be obtained in the subsequent reaction of the derived fluorescein isocyanate with proteins to give fluorescent protein conjugates[1].

The conventional method of separation of the two isomers consisting of fractional crystallization of the nitrofluorescein diacetates[1] is laborious and wasteful; to obviate this we have devised a chromatographic separation of the two isomers.

A kieselguhr column ('Hyflo-Supercel') is used with 0·2 *M* sodium phosphate buffer *p*H 8·0 (3 ml. of buffer to 5 gm. of kieselguhr) as stationary phase and a mixture of *n*-butanol and *cyclo*hexane as mobile phase. In Fig. 1 is shown the result obtained with a mixture of the aminofluoresceins that had been originally purified as the nitrofluorescein diacetates, using in this case as mobile phase *n*-butanol (65 per cent v/v) and *cyclo*hexane (35 per cent v/v). Peak 1 represents an impurity present in the crystalline aminofluorescein II (using the nomenclature adopted by Coons *et al.*[1]), peak 2 represents aminofluorescein II, peak 3 represents an impurity in the crystalline aminofluorescein I and peak 4 is aminofluorescein I. The time required for the separation was decreased by using gradient elution, the column being started with *n*-butanol (30 per cent v/v) – *cyclo*hexane (70 per cent v/v), and the concentration of *n*-butanol was raised continuously using an apparatus similar to that described by Donaldson *et al.*[2] with the addition of a magnetic stirrer. (Alcoholic alkali was added to the column eluate in order to increase the light absorption of the first two peaks.)

The method was scaled up to deal with larger amounts of material by the use of a column 70 cm. long and 3 cm. in diameter, containing 100 gm. of kieselguhr, attached to an automatic fraction collector. From 365 mgm. of crude aminofluorescein soluble in the column mobile phase, 179 mgm. of aminofluorescein I and 105 mgm. of aminofluorescein II were obtained, the impurities (peaks 1 and 3) running as separate bands being discarded. This gave yields based on the original nitrofluorescein of 36·2 per cent of aminofluorescein I and 21·2 per cent of aminofluorescein II (reduced to 23 and 14·3 per cent respectively after crystallization), whereas the use of fractional crystallization as the separation technique gave only 11·7 per cent of aminofluorescein I and 4 per cent of aminofluorescein II. The purity of the fractions obtained from the large column was checked by comparing them with those obtained by fractional crystallization by means of a paper chromatogram.

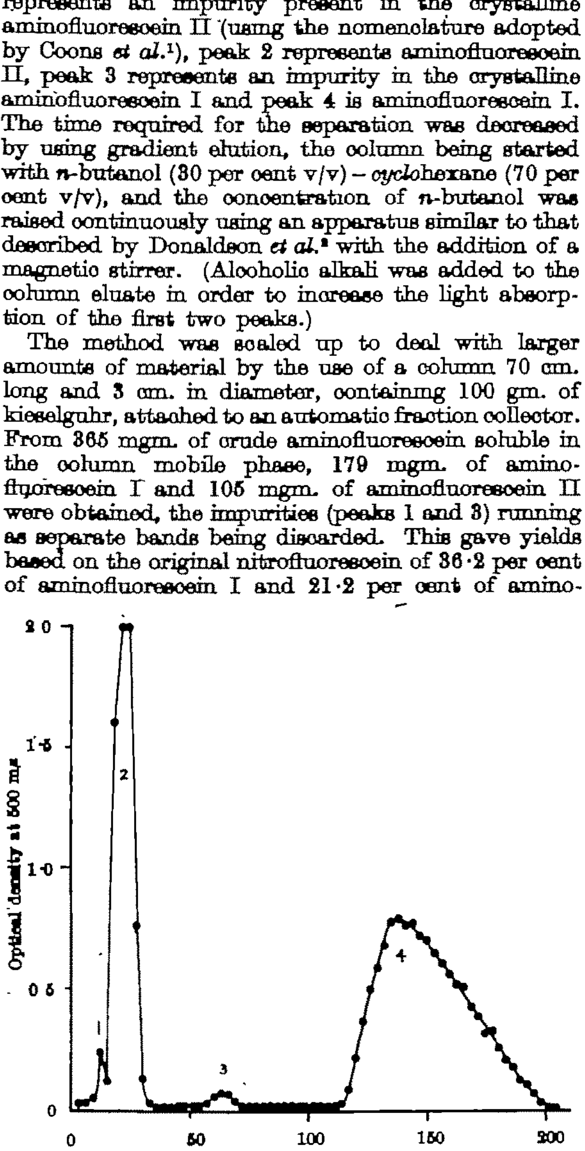


Fig. 1. Chromatogram run with a mixture of the two aminofluoresceins purified as the nitrofluorescein diacetates; mobile phase, *n*-butanol (65 per cent v/v) – *cyclo*hexane (35 per cent v/v). Peak 1, impurity present in aminofluorescein II; peak 2, aminofluorescein II; peak 3, impurity present in aminofluorescein I; peak 4, aminofluorescein I

Although this chromatographic technique is not suitable for very large quantities of material, the fact that only a few milligrams of aminofluorescein is required at any one time makes chromatography particularly suitable for the separation of the aminofluorescein isomers.

Ability of Normal and Sickle-Cell Hæmoglobins to form Complexes

The electrophoretic examination of hæmoglobin samples from Africans with sickle-cell trait, collected by one of us (Griffiths[1]), showed that the mobilities were not constant and did not agree with values reported by other observers (for example, Pauling *et al.*[2]). Among nine specimens we found values ranging from $-1 \cdot 6$ to $-3 \cdot 0 \times 10^{-5}$ cm./sec./V./cm. for the normal hæmoglobin component and from $-1 \cdot 2$ to $-2 \cdot 4 \times 10^{-5}$ cm./sec./V./cm. for the sickle-cell component. Seven normal hæmoglobin samples gave values between $-1 \cdot 7$ and $-3 \cdot 8 \times 10^{-5}$ cm./sec./V./cm. Not only did the mobility vary from individual to individual, but also samples taken from one subject varied from time to time. The values were all determined by electrophoresis in the Tiselius apparatus at a concentration of about 1·5 per cent of hæmoglobin, prepared by Drabkin's method[3], in phosphate buffer at *p*H 7·5 and ionic strength 0·1. Similar variations in mobility were shown by paper electrophoresis. The variations were not due to technical errors, because replicate determinations with a given specimen of blood gave concordant results. The absence of methæmoglobin or similar derivatives was shown by spectroscopic examination.

Many workers have reported that normal hæmoglobin can be resolved into fractions with differences in solubility, resistance to alkaline denaturation and gel formation. It is possible that the differences in electrophoretic mobility described here are a reflexion of such heterogeneity.

Usually the proportions of normal and sickle hæmoglobin components were reversed in the ascending and descending columns; a typical example is shown in Table 1. This reversal is the same as that found by Longsworth and McInnes[4] on electrophoresis of albumin – nucleic acid complexes. Jayle *et al.*[5] state that hæmoglobin forms a complex with haptoglobin, and Cheesman[6] showed that a complex is formed between hæmoglobin and ribonucleic acid. These facts suggested to us that such complex formation between hæmoglobin and some other constituent of the red cells might be responsible for the different mobilities observed, and that sickle-cell hæmoglobin

Table 1. MOBILITIES AND PROPORTIONS OF NORMAL AND SICKLE COMPONENTS IN SICKLE-CELL TRAIT HÆMOGLOBIN

Components	Mobility (cm./sec./V /cm. × 10^{5})	Proportion of total	
		Ascending (per cent)	Descending (per cent)
Sickle-cell hæmoglobin	2·3	54·0	32·1
Normal hæmoglobin	2·8	46·0	67·9

Table 2. MOBILITIES OF HÆMOGLOBIN COMPLEXES

Mixture	Mobilities (cm./sec./V./cm. × 10^{5})			
	Ascending		Descending	
	Slow	Fast	Slow	Fast
Hæmoglobin	2·1	—	2·0	—
Nucleic acid	16·5	20·0	16·9	—
Hæmoglobin + nucleic acid	2·5	19·9	2·2	17·6
Carbonic anhydrase	—	2·6	—	2·6
Hæmoglobin + carbonic anhydrase	1·1	1·6	1·1	1·6

might differ from normal hæmoglobin in being such a complex with some unidentified macromolecule.

To test the feasibility of this hypothesis, normal hæmoglobin was mixed with nucleic acid and the mixture dialysed against phosphate buffer and submitted to electrophoresis. The mobility of the original hæmoglobin was altered and a new peak, presumably corresponding to a hæmoglobin – nucleic acid complex, appeared (Table 2). Mixtures of carbonic anhydrase and hæmoglobin gave similar results, whereas globin – hæmoglobin mixtures gave three peaks. Reversal of the proportions of the components in the ascending and descending columns was also noted.

A corollary of this suggestion is that, if two samples of sickle-cell trait hæmoglobin with different mobilities are mixed and submitted to dialysis and electrophoresis, the original complexes may dissociate and then recombine to give two fresh peaks with mobilities intermediate between those observed in the separate samples, due to rearrangement between the sickle-cell and normal hæmoglobin components. Alternatively, if the original complexes are more firmly bound, the mixture of the two samples might give rise to four peaks with unaltered, or only slightly altered, mobilities and areas. We have found both sorts of result in such tests.

These results suggest that the abnormal hæmoglobins which have been described may not, in fact, be actual different hæmoglobins but complexes of normal hæmoglobin with some other macromolecule which is constantly present and genetically inherited, and which, in some instances, may so alter the solubility properties of the hæmoglobin as to give rise to the 'sickle' phenomenon.

Hæmolytic Anæmia produced Experimentally in the Guinea Pig by *T*-transformation of the Erythrocytes *in vivo* with Purified Concentrated Enzyme

DURING the continuation of work aimed at explaining the development and possible significance of the Thomsen phenomenon[1] *in vivo* (so-called polyagglutinability), it proved practicable to produce hæmolytic anæmia in guinea pigs by *T*-transformation of their erythrocytes *in vivo*. The term '*T*-transformation' applies to the production of the specific receptor-*T* in erythrocytes through the activity of an enzyme formed by various bacterial species[1].

In a preceding communication[2], it was described how *T*-transformation of the erythrocytes of guinea pigs *in vivo* can be induced by infecting animals with pneumococci. It has been found that *T*-transformation of the erythrocytes may also appear in guinea pigs in the course of spontaneous infection with *pnc.* 19. Furthermore, *T*-transformation *in vivo* can also be produced by giving animals intravenous injections of a solution of enzyme from *pnc.* 19. The present work was carried out with concentrated enzyme prepared by elution of the enzyme, combined with erythrocytes, on the lines described by Burnet *et al.*[3].

The investigation was commenced with several animals, but unfortunately some died early from irrelevant causes so that eventually only four experimental animals were available. The result appears so clear-cut, however, that its publication is thought to be of interest. As a matter of fact, in various ways, it has been confirmed by other experiments now proceeding.

The four animals were uniform as to size, age, sex and colour. Initially the amount of hæmoglobin, erythrocyte count and reticulocyte count were determined; and, for some time, the urine had been examined daily by the benzidine test and was found to be free from blood. The anti-*T* content of the serum was found to be considerable in two of the animals, but low in the other two.

In the two animals with high anti-*T* titre the erythrocytes were now *T*-transformed by intravenous injection of concentrated enzyme. The other two animals were given injections of the same amounts of saline, and they served as controls. Then, on every other day, hæmoglobin determination as well as erythrocyte and reticulocyte counts were carried out on all the animals. On every other day the erythrocytes were examined for *T*-transformation. The urine was examined daily for the presence of hæmoglobin. The animals—the *T*-transformed as well as the controls—suffered a loss of blood amounting to ¼–1 c.c. every other day. (The blood was taken from the ear as capillary blood, not withdrawn by heart puncture as the latter would have entailed a risk of internal hæmorrhage.)

In one of the animals whose erythrocytes were *T*-transformed, in the course of three days the hæmoglobin fell from 84 to 43 per cent; in the other animal of this group it fell in seven days from 99 to 46 per cent. The erythrocyte content showed a corresponding fall. The presence of hæmoglobin in the urine could be demonstrated in these animals during the first two days. No positive benzidine reaction could be ascertained in any of the other cases. The controls showed a fall in hæmoglobin from 91 to 90 and from 86 to 79 per cent, respectively, which corresponds to the presumably small loss of blood through sampling of the blood.

The two animals in which anæmia was produced were pale and weak, but icterus was not ascertained at any time. During the following two to three weeks, the hæmoglobin percentage and erythrocyte count rose again to normal values. In all the animals the fall in hæmoglobin was followed by a transitory increase in reticulocytes in the peripheral blood. Thus, in the two animals with pronounced fall in hæmoglobin, the reticulocyte count rose respectively from 0·2 and 0·4 per cent before the injection of enzyme to 17·8 and 19·0 per cent nine days after.

For the two controls the increase in the reticulocyte count was from 0·6 and 0·0 to 2·4 and 3·0, respectively.

The experiments described above will be reported in detail elsewhere.

Isolation of Mucic Acid from Fruits

MUCIC acid has only been recorded twice as occurring in natural products, namely, in putrified blood[1] and in the diffusion juice from sugar beet[2]. Pure mucic acid has now been isolated from sound ripe peaches and pears by methods which make it appear certain that the acid was present in the free state in the fresh fruit.

The extraction and separation of the acids was carried out as described previously[3], except that the solution of acid and sugars (after removal of the bases and amino-acids with a cation-exchanger) was run straight on to a column of a strong-base anion-exchanger in the acetate form. This column was placed above two or more smaller columns of the same resin in the acetate form, and the acids were displaced with $0\cdot1\,N$ hydrochloric acid. Paper chromatograms of the fraction(s) between the malic and citric acid bands contained an acid with $R_F = 0$ in methyl ethyl ketone – cineole – aqueous formic acid (53 per cent w/v) (50 : 50 : 36 v/v)[3], and $R_{\text{malic}} = 0\cdot9$ in alcohol – ammonia – water (80 : 5 : 15)[4]. The isolated acid and mucic acid behaved identically on paper chromatograms and ion-exchange columns. The acids were revealed by rapidly pulling the paper through a solution of silver nitrate in acetone, followed by (*a*) heating the paper for a few minutes at about 100° C., and then (*b*) spraying it with alcoholic sodium hydroxide (cf. ref. 5). The chromatogram was then fixed with sodium thiosulphate (5 per cent). After treatment (*a*), all acids gave a white spot; after (*b*) acids having an α,β-glycol or an α-keto group gave an intense black spot on a grey background.

When the fractions containing mucic acid were allowed to stand at + 1°, crystals separated. Recrystallization from sodium hydroxide – hydrochloric acid yielded an optically inactive acid of melting point 215° (decomp.)[6], not depressed by authentic mucic acid. The diphenylhydrazide had melting point 242° [6]: The acid from peaches gave on analysis C, 34·2; H, 4·8; O, 61·0; that from pears C, 34·1; H, 4·9; calc. for $C_6H_{10}O_8$: C, 34·3; H, 4·8; O, 60·9 per cent. About 100 mgm. of mucic acid was isolated from 2 kgm. of ripe peaches or pears. Apricots, passion fruit and blackberries probably contain mucic acid in variable amounts, since crystalline precipitates, melting point 214–215°, were isolated from them by the same method.

Effect of Silver Ions on Mitochondrial Adenosine Triphosphatase

Abood, Gerard and Ochs[1] claim that the respiration of cell-free dispersions and mitochondria of brain tissue was increased by the passage of electrical impulses between silver electrodes in the suspension medium. In general, increase in the respiratory rate of well-prepared mitochondria is consequent upon increase in the rate of removal of adenosine triphosphate, by addition of systems which catalyse its dephosphorylation, or through activation of the mitochondrial adenosine triphosphatase[2]. We were thus led to test the effect of electrical impulses on the adenosine triphosphatase activity of mitochondria, obtained from rabbit cerebral cortex, using the medium which had enabled the preparation of mitochondria of low initial adenosine triphosphatase activity from pigeon breast muscle[3]. For the adenosine triphosphatase assays the particles were incubated for 10 min. at 20° in a medium of the following approximate composition: $0\cdot1\,M$ potassium chloride, $0\cdot05\,M$ ammo*tris*hydroxymethylmethane-hydrochloride buffer *p*H 7·4, $0\cdot005\,M$ magnesium sulphate, $0\cdot005$–$0\cdot0075\,M$ sodium adenosine triphosphate, and $5 \times 10^{-5}\,M$ ethylenediaminetetraacetate. With $0\cdot0075\,M$ adenosine triphosphate, mitochondria from 60 mgm. of tissue liberated about 20 μgm. of inorganic phosphate under these conditions, and the activity was increased three-fold on addition of $10^{-4}\,M$ 2 : 4-dinitrophenol.

Electrical impulses (2–3 V., 25–75 m.amp., 50 c./sec.) were applied during the incubation through dipping electrodes (type *G* of Ayres and McIlwain[4]). With gold and molybdenum electrodes, there was no effect on the adenosine triphosphatase activity; but with silver electrodes the rate of phosphate liberation increased two- to three-fold. However, the mere presence of the silver electrode, without passage of current, or addition of low concentrations (10^{-6} to $10^{-5}\,M$) of silver nitrate, led to similar increases in adenosine triphosphatase activity.

In a paper[5] which appeared after the conclusion of these experiments, Narayanaswami and McIlwain state that pulses from molybdenum electrodes did not affect adenosine triphosphatase activity of dispersions of cerebral tissue, and, indeed, caused only a small increase in the respiration of brain mitochondria. Our experiments, however, disclosed the stimulation of mitochondrial adenosine triphosphatase by silver ions; and, since dinitrophenol also has this effect, it was of interest to determine whether silver ions behave similarly to dinitrophenol in other systems. The adenosine triphosphatase activity of pigeon breast muscle mitochondria was increased some five times by 10^{-5} *M* silver nitrate (optimal concentration). The reversal of the spontaneous swelling of muscle mitochondria *in vitro* by adenosine triphosphate, an action inhibited by dinitrophenol[5], was also inhibited by low concentrations of silver nitrate; brain mitochondria behaved similarly. On the other hand, the calcium-activated adenosine triphosphatase of myosin, which is stimulated by dinitrophenol[6] in rather high concentrations (for example, 60 per cent acceleration at 2×10^{-3} *M* [7]), is not stimulated by silver ions; under our conditions (*p*H 7·0, L-myosin 17 μgm. nitrogen/ml.) there was inhibition above 3×10^{-6} *M* silver ions (cf. ref. 8), and no acceleration at lower concentrations down to 10^{-7} *M*.

If silver ions stimulate adenosine triphosphatase activity of mitochondria, they might be expected to accelerate their respiration. Abood *et al.*[1] found no effect of 10^{-5} *M* silver ions on the respiration of brain dispersions; but we observed, with pyruvate together with malate as substrates, about 200 per cent acceleration of the respiration of brain mitochondria by 5×10^{-6} *M* silver nitrate.

We thank Dr. S. V. Perry for helpful discussions, and Dr. D. M. Needham for help in the preparation of the myosin. Acknowledgment is made to the Medical Research Council for continued support in the form of a research training grant to one of us (J. B. C.).

Electrolyte Concentrations in Red Blood Cells of British Breeds of Sheep

DURING preliminary experiments on the electrolyte balance of adrenalectomized Scottish Blackface ewes, it became apparent that the concentrations of potassium and sodium in the red blood cells in this breed were not constant. Further examination revealed that they fell into two distinct groups in phenotypically similar animals.

This observation has now been extended to a larger sample of the breed. As the plasma sodium and potassium concentrations were the same in the two groups, a photometric examination of the whole blood enabled a satisfactory separation of the two electrolyte types to be made. It was found that the whole-blood sodium concentration varied inversely with that of the potassium. A separation into the two electrolyte types using sodium concentrations alone was not possible, however. Results are plotted in Fig. 1.

Ninety-three Scottish Blackface sheep were examined: eighty for both potassium and sodium and thirteen for potassium only. Of these, forty-seven were shown to belong to a type in which the concentration of potassium ranged about a mean value of 36 m.equiv./l., whereas forty-six belonged to a group which ranged about a mean of 13 m.equiv./l. These will be referred to as type *HK* and type *LK* respectively.

Sodium and potassium determinations were made on both plasma and whole blood in sixteen of these Blackface sheep—eight of each type—together with hæmatocrit readings. The red cells, by difference, were calculated to contain mean values of 34 and 80 m.equiv./l. sodium and mean values of 89 and 24 m.equiv./l. potassium.

As a 1 : 1 ratio for *HK* and *LK* types of sheep had not been reported previously, it was decided to examine another breed to see if this ratio was peculiar to the Scottish Blackface sheep or whether the ratio varied from breed to breed. A total of forty-three Cheviots was examined, thirty-nine for both potassium and sodium and four for potassium only. Of these, seven were shown to belong to the *HK* type and thirty-six to the *LK* type.

While this work was in progress, Widdas[2] published the results of an examination of twenty-two pregnant Welsh ewes, in which he found eight animals to belong to the *HK* type and fourteen to the *LK* type.

It is clear that, so far as the concentrations of sodium and potassium in the red cells are concerned in the three breeds examined, two types exist, and the distribution between groups varies from breed to breed.

The majority of merino sheep[1] appear to belong to the type *LK*, whereas representatives of both types have been recorded together with intermediate types in the Lebanese fat-tailed sheep[3]. It is intended to examine further the percentage distribution of the two types already recognized in the British breeds of sheep and to see whether intermediate types exist. Should the homogeneity of the merino and the heterogeneity of the fat-tailed sheep be confirmed when larger numbers are examined, there may then exist a method for a further study of the evolution and migration of the Ovidae. The role of electro-

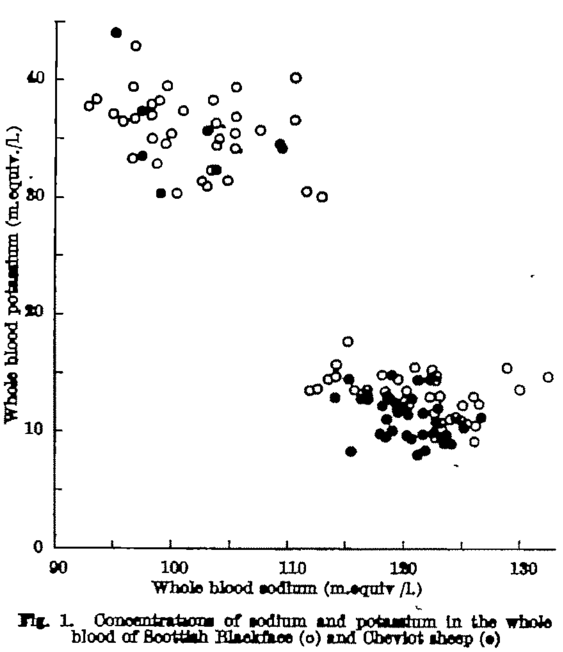

Fig. 1. Concentrations of sodium and potassium in the whole blood of Scottish Blackface (○) and Cheviot sheep (●)

lytes, and particularly of sodium and potassium, in the reaction of the body to unfavourable circumstances, suggests that it is important to determine whether there is any fundamental difference in the reaction of these two distinct types of sheep.

Storage of Plant Mitochondria

ONE of the difficulties encountered in the purification of many plant enzymes is their low concentration in the intact cell. When enzymes are contained in the mitochondria, considerable concentration of such enzymes can be achieved by using isolated mitochondria as the starting material for further purification. An example of this approach is the purification of the acetate-activating enzyme of beef heart[1]. Millerd and Bonner[2] have pointed out that the difficulty in using this method in the case of plants is that no convenient sources exist for the isolation of large quantities of plant mitochondria. It has now been found that plant mitochondrial suspensions may be stored in the frozen state for at least thirty days. Although the activity of the mitochondria gradually decreases, the ability to store such suspensions makes possible the accumulation of relatively large quantities of material which can then be used for the isolation of specific enzymes.

Seeds of Algerian oats, *Avena sterilis* (L.) Mal. s. sp. *byzantina* (C. Koch) Thell., were soaked in water for 2 hr. and sown in moist vermiculite. They were grown in the dark at 26·6° C. for 6 days. At this stage, the above-ground portions of the plants, representing the coleoptiles, first leaves and first internodes, were about 6 cm. high. Mitochondria were prepared from the above-ground portions of the plants as previously described[3], using 0·5 *M* sucrose–0·01 *M* ethylenediaminetetraacetic acid, *p*H 7·0, as the homogenizing medium. The mitochondria were freed of ethylenediaminetetraacetic acid by suspension in 0·5 *M* sucrose and recentrifugation. The washed pellet was suspended in 0·5 *M* sucrose and the volume adjusted so that the nitrogen content of the suspension was 0·6–1·0 mgm. per 0·5 ml. The suspension was divided into 3–5 ml. portions and stored in 25-ml. Erlenmeyer flasks at approximately – 19° C. The mitochondria were assayed immediately after preparation and after various periods of storage. Thawing was accomplished by swirling the flasks for about 45 sec. in a constant-temperature bath maintained at 30° C.

The rate of oxidation of pyruvate in the presence of catalytic amounts of succinate was taken as an index of the activity of the mitochondria. Oxygen uptake was measured manometrically by the method of Warburg[4], and nitrogen was determined as previously described[3]. Results of representative experiments are presented in Table 1. The values given are for the total oxygen consumed in 60 min. and were corrected for the endogenous oxygen uptake. The rates of oxygen uptake were linear for 60 min. when the mitochondria were assayed immediately after preparation; but after storage, the rates usually declined somewhat during the second 30-min. period. The endogenous oxygen consumption, and the consumption in the presence of 0·001 *M* succinate, were of the order of 16 and 28 per cent respectively of the oxygen uptake in the presence of pyruvate plus succinate.

Table 1. OXIDATION OF PYRUVATE BY *Avena* MITOCHONDRIAL SUSPENSIONS AFTER VARIOUS PERIODS OF STORAGE IN THE FROZEN STATE. Final concentration of reagents: phosphate buffer (KH_2PO_4–K_2HPO_4) at *p*H 7·2, 2 × 10^{-2} *M*; magnesium chloride, 2 × 10^{-3} *M*; adenosine triphosphate, 10^{-3} *M*; diphosphopyridine nucleotide, 10^{-4} *M*; sucrose, 0·4 *M*; pyruvate, 2 × 10^{-2} *M*; succinate, 10^{-3} *M*; enzyme suspension, 0·5 ml. Final volume, 3·0 ml.; 0·2 ml. 10 per cent potassium hydroxide in side-arm. Gas phase, air. Temperature, 30° C.

Exp.	mgm. Nitrogen per 0·5 ml. mitochondrial suspension	Storage in days	mm.^{3} Oxygen absorbed per mgm. nitrogen in 60 min.

2	0·64	0	178
		21	92
		30	70
3	0·75	0	130
		23	79

In Fig. 1, the relative activity of the mitochondria is plotted as a function of the length of storage. The initial activity of a suspension was taken as 100. From these results, it appears that *Avena* mitochondria retain about 50 per cent of their initial activity after 25 days in storage at – 19° C. During this length of time, it is possible to accumulate large quantities of mitochondria.

The rapidity with which the mitochondrial suspensions are thawed appears to be a critical factor in the maintenance of activity. The results of two experiments to determine the effect of rapidity of thawing on the activity of mitochondrial suspensions are presented in Table 2. Rapid thawing at 2° and at 30° C. gave equally active preparations; but considerable loss of activity occurred when suspensions were thawed slowly at 2° C. After standing at 2° C. for 20 hr., even freshly prepared mitochondrial suspensions were completely inactive.

Experiments are in progress to determine the sensitivity of individual mitochondrial enzymes to low-temperature storage, and also the optimum conditions for storage.

Effect of Thyroxine on Sexual Behaviour in the Ewe

The administration of thyroprotein to female rats caused an increase in weight of the ovaries, with histological evidence of intense luteinization[1]. It was found that iodinated casein proved beneficial in improving libido and fertility in inactive bulls. It has also been found to overcome 'summer sterility' in rams[2]. So far, little work has been carried out to investigate the effect of thyroxine on the various reproductive processes in the ewe.

In an experiment conducted at the Animal Research Station, Cambridge, to investigate the effect of orally administered L-thyroxine on wool production in the ewe, nineteen ewe lambs were used. Five of them were given L-thyroxine in gelatin capsules daily for eleven months from August 15, 1952, to July 17, 1953. For the first six weeks the dosage was 3·5 mgm.; it was raised to 5 mgm. for the next six months and then maintained at 4·5 mgm. for the last three and a half months. After two months of the cessation of thyroxine administration and at the beginning of the breeding season (October 1953), when the treated ewes were allowed to run with the ram, they exhibited hyper-sexual activities characteristic of male behaviour, namely, jumping and mounting other animals. These symptoms took place at the normal breeding season. It appears that an intensification of the normal œstrous behaviour took place at about the time of ovulation. However, these ewes were served and lambed as normal.

Another experiment was conducted to investigate this effect and also the possibility of bringing the ewes on heat during the anœstrous period. Of ten ewes, five were fed daily 7 mgm. L-thyroxine from April 1 to May 20, 1954, the other five being used as controls. They were running continuously with a vasectomized ram. The ram's briskets were ochred daily and the ochre colour was changed every fourteen days. Observations for œstrous were carried out daily. None of the treated ewes was served by the ram. However, two ewes showed the same type of hypersexual activity as had been observed previously. The two ewes did not attract the attention of the ram running with them, and neither did the other ewes. The ram was changed and replaced by another ram known to have recently served artificially œstrous ewes, but this ram also did not serve the two ewes. Moreover, the two ewes did not show normal œstrous periodicity. They were active intermittently, with never more than four or five days rest. Laparotomy was performed on the more active of the two ewes the day after it was observed to be active. Both ovaries were very small and showed no sign of follicular activity. These observations seem to be a more abnormal type of behaviour not linked to ovarian activity. Perhaps the best way to explain these results would be to attribute this behaviour to an effect on the central nervous system. It is well known that, in the human, hyperthyroid individuals tend to be over-excitable.

J. Hammond, jun.[3], observed jumping on other ewes by an ancestrous ewe injected with stilbœstrol. He also observed it once in a normal ewe at œstrous and often in normally œstrous ewes after stilbœstrol injection (personal communication). He offered the opinion that such male behaviour seems to be due to prolonged stimulation rather than to heavy dosage of œstrogen. However, there is no evidence that in the animals treated with thyroxine œstrogen secretion was at all enhanced.

So far as bovine fertility is concerned, it is of great importance to have a wider knowledge of the effects of hyperthyroidism induced by the administration of thyroxine on ovulation and implantation of the fertilized ova.

I am indebted to Dr. John Hammond for his guidance and advice, and to Mr. J. Hammond, jun., for suggestions during the course of the present investigations.

Phenetidine in Urine

The urinary substance referred to as *B* in a previous communication[1] has now been isolated in pure form. It can be shown to be *p*-phenetidine by its infra-red and ultra-violet spectra, the melting point of a picrate (176–180° C.) and lack of depression of melting point in a mixture with authentic *p*-phenetidine picrate (179–181° C.). It is present in urine as a labile acidic substance which can be precipitated by lead acetate and purified by paper chromatography from butanol–acetic acid (R_F about 0·5). The precursor seems to be a conjugate with sulphuric acid. About 2–3 per cent of administered phenacetine is excreted in this form.

Substance *B* was believed to be a tryptophan metabolite because a compound with the melting point of quinaldic acid was isolated from the urinary concentrates, and spectroscopic evidence for a derivative was compatible with *o*-aminobenzyl alcohol until comparison with authentic samples became possible. Numerous compounds with similar ultra-violet spectra could be differentiated using the characteristic shifts of the absorption maxima in three solvents: 0·05 N hydrochloric acid, 0·1 N ammonia and ethylether.

The reported biological relationship of substance B (*p*-phenetidine) can be explained by (*a*) suppression of kynurenine excretion by some constituent of the antipyretic–analgesic mixtures containing phenacetine. Phenacetine itself fails to suppress the excretion of kynurenine. The second factor (*b*) seems to be increased need of analgesics in patients on a meat-free diet. The occurrence of phenetidine in apparently healthy people may be an index of self-medication (about 10 per cent).

Thanks are due to the National Cancer Institute of Canada for financial assistance, and to Drs. J. Patrick and K. Wiesner for samples of *o*-aminophenylmethylcarbinol and *o*-aminobenzylalcohol, respectively.

Chromosomal Biotypes in Emmer Wheat

THE emmer wheat (*Triticum dicoccum* Schrank) and some of its varieties are known for their resistance to black rust, and the Indian emmer or khapli is extensively used in breeding rust-resistant varieties. It is usually grown in Central and Southern India and is commonly known as khapli wheat; botanically it is *Triticum dicoccum* Schrank var. *farrum* Bayle. According to Percival[1], the Indian and Abyssinian emmers have had a common origin and both are allied to *T. dicoccum* Schrank var. *ajar* Percival.

In a collection of the Indian emmer wheats (khapli) at the Indian Agricultural Research Institute, New Delhi, two distinct races have been discovered differing from each other with respect to certain characters. These are shown in Table 1.

The two types also differ cytologically in having either one or two pairs of *SAT*-chromosomes. As is well known, all the tetraploid wheats ($2n = 28$), including *T. dicoccum*, have two pairs of *SAT*-chromosomes, whereas these types, provisionally called biotypes 1 and 2, breed true to their chromosome type, that is, the number of *SAT*-chromosomes (Fig. 1). So far as we know, such chromosomal biotypes have not been hitherto reported in emmer wheat and perhaps also not in other species of the genus *Triticum*. In barley, however, chromosomal biotypes have been recently reported by Hagberg and Tjio[2].

Table 1

Characters	Biotype 1	Biotype 2
Length of ear	13·0 cm.	9 0 cm.
Pollen size	44·5–64·7 µ	48 0–68·0 µ
Pollen fertility	79·0 per cent	97·4 per cent
Grain-setting	67 5 per cent	90·0 per cent
Grain size	9 0 mm. long 2·5 mm. wide	8·0 mm. long 2·3 mm. wide

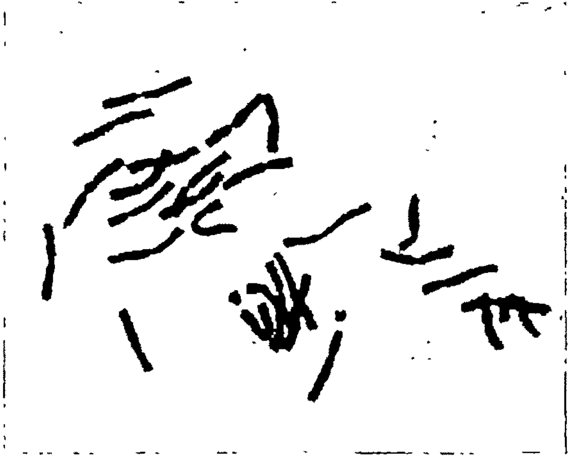

Fig. 1. *T. dicoccum* Schrank; $2n = 28$, with only one pair of *SAT*-chromosomes

Fertility and grain-setting in interspecific crosses between khapli (*T. dicoccum*) and bread wheat (*T. aestivum*) have been variously reported by different workers. Haynes[3] succeeded in getting fertile F_1 plants in reciprocal crosses between "Federation" and khapli. In crosses between "Garra", "Steinwedel" and khapli, Waterhouse[4] obtained as high as 65 per cent of grain-setting. Pal[5] has reported the F_1 hybrids between khapli and bread wheat to be "fairly highly fertile", while Bhatia[6] has recorded some seed-setting in similar crosses, but his F_1 plants did not grow to maturity. Recent observations at this Institute, however, have given almost the opposite results. Crosses made between khapli and bread wheat have given consistently highly sterile F_1 plants. This confirms the observations made earlier by Hayes and Stakman[7]. In view of the occurrence in Nature of two chromosomal biotypes of khapli, differing in their relative fertility, such variation in the fertility of F_1 hybrids, as observed by previous workers, is not only possible but also significant. Further studies on the behaviour of the hybrids of the two biotypes of khapli and types of *Triticum aestivum* in various combinations are likely to throw much light on: (i) the problem of relative fertility of the hybrids; and (ii) the relative resistance of the hybrids to the different races of black-rust.

We thank Dr. B. P. Pal, director, and Dr. R. D. Asana, head of the Division of Botany, Indian Agricultural Research Institute, New Delhi, for giving the material and facilities to conduct the present investigation.

A Supernumerary Pelvic Fin in the Powan (*Coregonus clupeoides* Lacépède)

An abnormal pelvic structure in the form of an additional median fin (Fig. 1) was first observed in the powan during field studies on the population of this species of whitefish in Loch Lomond in 1951. Between 1951 and 1953 eighteen fish, representing 1·5 per cent of the total number examined, were found to have this abnormality; its occurrence is independent of sex of the fish or of their regional location in the lake. All these fish were two or more years old, but one specimen reared in the laboratory showed that the structure first appears at the age of about six months.

The additional fin occupied the same position in all specimens, lying in a median vertical plane with its base set symmetrically between and slightly in front of the bases of the paired pelvic fins. Externally, it projected from the ventral surface to an extent which varied widely without relation to size of fish. In its smallest form it appeared as a mere knob 2 mm. in length, in better developed forms as a translucent and rigid spike or blade and in the most highly developed example it was three-quarters of the length of the pelvic fin, flexible and with dark pigmentation towards the free edge.

The skeletal features of the abnormal specimens were examined initially by radiography and some visually after staining with alizarin red for bone or victoria blue for cartilage and clearing. The skeleton of a well-developed additional fin consisted of a pair of small anterior bones, presumably the elements of a fin ray, behind which there were nine separate rays, long and halved, with their bases enlarged. The stems of the rays were jointed and branched distally into tapering filaments as in normal lepidotrichia. The ray bases were hinged to an elongate structure of bone and cartilage consisting of an anterior and a posterior element closely apposed. The anterior and larger element possessed lateral cartilages with which the inner surfaces of the half-rays articulated, and the hind end of the posterior element lay just in front, and quite independent of, the median symphysis of the broad posterior part of the normal pelvic bones. As there were no other bones in the abnormal structure, these two elements may correspond to radial bones. They had a shallow seating on the median ventral tendon connecting the protractor and retractor ischial muscles to the pelvic arch but appeared to have no connexion with this tendon, being held in position by connective tissue only. No muscles appeared to be associated with the abnormal fin, and the muscles serving the paired pelvic fins were similar to those in normal powan.

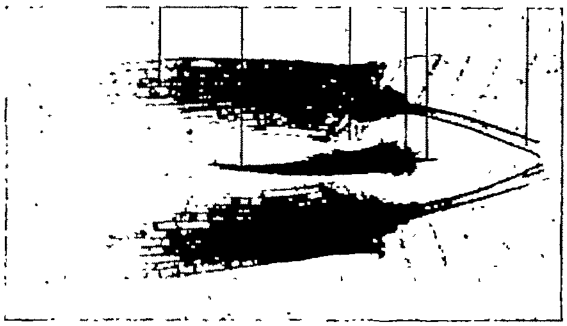

Fig. 1. X-ray positive of supernumerary fin, ventral view. *A*, Flexible rays; and *B*, their massive bases; *C*, bony projection of anterior element of supporting structure; *D*, normal pelvic fin (right); *E*, broad post-median part of pelvic bone (right); and *F*, its elongate anterior end

The average complement of rays and their pattern was the same in the paired fins of normal fish and those with the additional median fin. This fin therefore does not appear to have been derived from elements of the pelvics or to be connected in any way with them. It may be regarded as a true supernumerary fin the origin of which is uncertain. A more detailed description of its structure will be given elsewhere.

The occurrence of an additional fin in the pelvic region is now known to be present in two other members of the genus *Coregonus*. It has been reported (M. Dottrens, personal communication, 1953) to exist in approximately one per cent of the population of whitefish in Lac de Thoune, Switzerland, in a variety of *Coregonus wartmanni* known as the albock. In 1953 a similar abnormality was discovered in one of sixty specimens of the schelly (*Coregonus clupeoides stigmaticus*) from Ullswater in the English Lake District (G. J. Thompson, personal communication, 1953). The powan and schelly belong to the same British species and *C. wartmanni* is generally considered to be their closest relation among the numerous coregonid fishes in the continent of Europe. Since this abnormality has appeared in three isolated populations, further study may reveal whether it is attributable to a mutant genetic factor in this particular group of coregonids or in the genus as a whole. If it is restricted to the former, then it may provide a clue to their distribution in the Old World.

My thanks are due to Prof. C. M. Yonge and to Dr. H. D. Slack for their support and assistance, and to Dr. E. Trewavas, curator of fishes in the British Museum (Natural History), for technical advice.

A Curious Ecological 'Niche' among the Fishes of Lake Tanganyika

Previous studies on certain Tanganyika Cichlids[1] have shown that, in species of the genus *Plecodus*, the stomach content is often composed of fish scales. It was not known if this was an indication of a very peculiar diet, and whether these scales had been taken from live or dead fish.

By collecting live and dead specimens of *Plecodus straeleni* Poll, *Plecodus paradoxus* Boulenger and a dead specimen of a *Pl. elaviae*, we are in a position to answer these questions. In one dead specimen of *Pl. straeleni* we have found the stomach full of ctenoid scales and in another one, of *Pl. paradoxus*, the stomach was full of Cichlid and Cyprinid scales, and did not contain any other food. In an aquarium we have been able to observe two *Pl. straeleni* feeding on the scales of a new species of *Lamprologus*, on those of *Lamprologus compressiceps* and of *Callochromis macrops*, all of which are bigger than the *Plecodus*.

It seems very difficult to feed *Pl. paradoxus* on earthworms, fish powder or insects. As for *Pl. straeleni*, we have been unable to feed them on any-

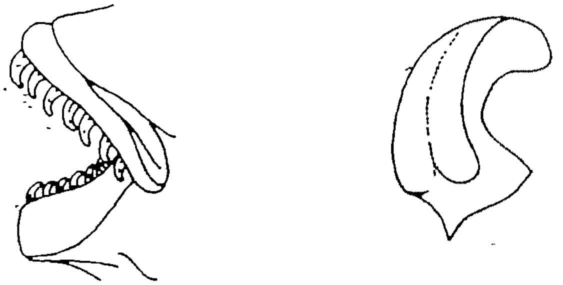

Fig. 1. *Plecodus paradoxus* Blgr. Dentition and isolated tooth (lateral view) after Poll (1948)

thing other than scales of live fish. When a *Plecodus* succeeds in attacking a fish, it pushes its mouth against the back of its victim for a short while. Then it swims away, leaving a denuded spot.

In the aquarium it seems that some species of fish know how to escape the attack of *Plecodus*, and they are able to drive them away from their shelter. For example, we have never seen a *Plecodus* 'scaling' a *Lamprologus savoryi* Poll, though a frequent fish in the *Plecodus*' environment, or a *Lobochilotes labiatus* or a *Simochromis curvifrons*. Some other fishes swim away from a *Plecodus* as soon as it appears (for example, *Lamprichthys tanganicanus*).

Of the four species of *Plecodus* (*Pl. paradoxus*, *straeleni*, *elaviae*, *multidentatus*) the first three were caught above a rocky bottom, the fourth one, above a muddy bottom, at considerable depth (90 m.). The first two are more littoral than *Pl. elaviae*. Sometimes, native fishermen catch *Pl. paradoxus* and *elaviae* with lines, baited with pieces of a small fish (*Stolothrissa tanganicae*). Thus it seems that adult *Plecodus* may secondarily turn to true carnivorous habits.

This peculiar way of feeding, so far as we know, has not been described in any marine fish, and the problem is how it has evolved from typical voracious habits. However, the dentition of *Plecodus*, with powerful band-like teeth, bending backwards (Fig. 1), seems, as Poll's figures show it, to be well adapted to that particular diet.

Occurrence of a Species of *Ornithodoros* in Britain

WHILE visiting Puffin Island, at the north-east end of the Menai Straits (North Wales) on May 16, 1954, about a dozen specimens of an argasid tick consisting of late nymphal stages and adults of both sexes were collected from under a stone in a dry part of the cliff. They possessed the movable cheeks to the camerostome; the legs, which were micromammilate, lacked dorsal humps, and the disks on the dorsal surface of the body were large and conspicuous. They were identified as an *Ornithodoros* species of the *talaje* group. A critical examination of this group by comparison with specimens from the British Museum (Natural History) is now being made.

The presence of *Ornithodoros* in Britain is interesting for two reasons: (1) several species are well-known carriers of a number of important diseases; and (2) the genus has been regarded as confined to the tropics and sub-tropics. So far as we are aware, apart from this occurrence in Britain, the most northerly records of the species of the *O. talaje* group are from the Central and Eastern Mediterranean countries.

A second visit on June 9 to Puffin Island showed the incidence of *Ornithodoros* was much greater than we had hitherto imagined. The ticks were found under stones some twenty feet above high-water mark in a well-defined zone of soft fossiliferous calcareous shale which has been more extensively weathered and therefore recessed a foot or two between harder layers of Lower Carboniferous limestone. They occurred in this dry region in company with the beetle *Harpalus latus* (L.), the bristle tail *Petrobius maritimus* Ouds., the earwig *Forficula auricularia* L., and the mite *Molgus littoralis* (L.).

The rest of this small island was examined with the view of determining the distribution, and it was found that the ticks were present along the whole of the north-west cliff and around the north-east tip of the island, but only in places where this particular stratum was exposed. Numerous limestone outcrops, old limestone walls and a large number of nests of herring and lesser black-backed gulls over the top of the island were examined without success.

The numbers present on the island must amount to many thousands, for under small stones not more than six inches in diameter there were 10–100 ticks. The majority of these were in the adult stage, and a rough count showed that 1 per cent were engorged. Large numbers of egg clusters were also noted alongside adults during this second visit.

Although rabbits occur on the island, the main hosts were thought to be birds, and this was substantiated by the presence of avian blood in the engorged ticks. Curiously enough, the main concentrations of these ectoparasites were some way removed from any bird colonies, and in one or two instances the nearest nests on the same ledge were 70 ft. away, although nests up the cliff face were probably no farther than 40 ft. Nesting sites near the tick areas were examined, and one or two *Ornithodoros* were present in some nests of cormorant, shag, razorbill and herring gull. Many chicks of the last species occur on the rock ledges near the ticks and these are possibly the main hosts.

It is clear that this tick is well established as a breeding species in this locality. Whether it occurs in similar situations around the British Isles remains to be seen. We have taken the opportunity of examining the sea-bird colony on Bardsey Island, off the tip of Caernarvonshire, but no *Ornithodoros* were found. However, it is of interest to note that the ixodid tick, *Haemaphysalis punctata* (Can. et Fanz., 1877), which has hitherto been recorded in the British Isles only from south-east England, was common here in rough pastures.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 15

University of London (at Guy's Hospital Medical School, St. Thomas' Street, London, S.E.1), at 5.15 p.m.—Dr. Christian Hamburger (Copenhagen): "The Excretion of 17-Ketosteroids in Human Urine".*

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. E. C. Cherry: "Information Theory".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Has Nuclear Fission a Future as a Source of Industrial Power?".

Society of Chemical Industry, Pesticides Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. C. C. Tanner: "The Statistical Approach to Crop Protection Research".

Aslib (at the Royal Society of Arts, 8 John Adam Street, Strand, London, W.C.2), at 6 p.m.—Dr. Alexander King: "The Work of International Organizations and Foreign Documentation Centres".

Tuesday, November 16

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. C. W. Allen: "Activity in the Sun's Atmosphere".*

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 2.30 p.m.—Celebration of the Jubilee of the Thermionic Valve. The Most Honourable the Marquess of Salisbury, K.G., P.C.: Opening Address; Prof. G. W. O. Howe: "The Genesis of the Thermionic Valve"; Sir Edward Appleton, F.R.S.: "Thermionic Devices from the Development of the Triode up to 1939"; Dr. J. Thompson: "Developments in Thermionic Devices since 1939".

Physical Society, Low Temperature Group (joint meeting with the Institution of Chemical Engineers, in the Science Museum Lecture Theatre, Exhibition Road, London, S.W.7), at 4.30 p.m.—Dr J. W. L. Kohler (Eindhoven): "Gas Refrigerating Machines".

Institute of Physics, Electronics Group (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. J. V. Jelley: "Čerenkov Radiation".

Physical Society, Acoustics Group (in the Physics Department, Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 5.30 p.m.—Mr. A. Tumarkin: "On the Function of the Middle Ear—Evolution and Degradation".

Society of Chemical Industry, Plastics and Polymer Group (in the Rooms of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. N. A. Hawthorn: "The Electrical Properties of Plastics".

Institution of Mechanical Engineers, Hydraulics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "Measurement of Flow".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Dr. H. T. Goodwin: "Uses of the 'Ace' Computer".

Wednesday, November 17

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Prof. F. L. Warren: "Electrophoresis of Plasma Proteins".*

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. Leslie H. Lampitt: "Science and Food Production" (H. Frankland Armstrong Memorial Lecture).

Institute of Petroleum (at the Royal Institution, Albemarle Street, London, W.1), at 4.30 p.m.—Mr. C. A. P. Southwell: "Winning Petroleum—a Story of British-American Co-operation" (Cadman Memorial Lecture).

Royal Meteorological Society (at 49 Cromwell Road, South Kensington, London, S.W.7), at 4.45 p.m.—Discussion on "Water Supply".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Lord Piercy of Burford, C.B.E.: "The Macmillan Gap and the Shortage of Risk Capital" (Inaugural Address of the President).

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. Christopher Ounsted: "Genetic and Social Aspects of the Epilepsies of Childhood".*

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. H. Heywood: "The Microscopes of John Marshall".

Royal Institute of Chemistry, London Section (at the Institute of Metals, Grosvenor Gardens, London, S.W.1), at 6.30 p.m.—Annual General Meeting. Sir Harry Jephcott: "Professional Status".

Royal Aeronautical Society (at 4 Hamilton Place, London, S.W.1), at 7.30 p.m.—Captain J. L. Pritchard, O.B.E.: "Bird Flight and the Aeroplane" (Graduates' and Students' Section Lecture).

Wednesday, November 17—Thursday, November 18

Iron and Steel Institute (at 4 Grosvenor Gardens, London, S.W.1)—Autumn General Meeting.

Wednesday, November 17—Saturday, November 20

National Physical Laboratory (at Teddington, Middlesex)—Symposium on "Precision Electrical Measurements".

Thursday, November 18

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Special General Meeting. Mr. W. A. Sexton: "Chemotherapeutic Research at the Laboratories of Imperial Chemical (Pharmaceuticals), Ltd., at Manchester".

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. R. H. Jeffers: "The Collected Correspondence of Richard Pulteney, M.D., F.R.S. (1730–1801)"; Mrs. P. D. Wilson: "Mrs. A. W. Griffiths of Torquay and the Early History of Marine Botany in Britain".

Institution of Electrical Engineers, Utilization Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. C. J. Beavis: "The Use of Electricity in the Production of Calcium Carbide".

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. H. Kramers (Delft): "Heat and Mass Transfer. 1: Unsteady States".*

University of London, British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. A. G. Everson Pearse: "Histochemistry and its Applications to the Basic Sciences"*. (From a series of lectures on "The Scientific Basis of Medicine".)

Society of Chemical Industry, Road and Building Materials Group (in the Lecture Hall of the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Dr. L. J. Wood: "The Constitution and Structure of Coal Tar Pitch".

Chemical Society (in the Large Chemistry Lecture Theatre, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 7.30 p.m.—Prof. M. J. S. Dewar: "Molecular Rearrangements" (Tilden Lecture).

Friday, November 19

Royal Society of Medicine, Epidemiology and Preventive Medicine Section (at 1 Wimpole Street, London, W.1), at 4.30 p.m.—Discussion on "The ABO Blood Groups and Disease". Opening speakers: Prof. Ian Aird, Miss A. M. Dickins and Dr. J. A. Fraser Roberts.

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Captain F. J. Wylie, R.N.: "The Cause of 'Radar-assisted Collisions'".

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Mr. G. W. H. Gardner: "Guided Missiles" (James Clayton Lecture).

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. H. Kramers (Delft): "Heat and Mass Transfer. 2: Gas Absorption".*

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Dr. G. B Foster: "The Analyst in the Fine Chemicals and Pharmaceutical Industries".

British Glaciological Society (in the Geology Department, The University, Oxford), at 8.15 p.m.—Discussion meeting on "Recent Trends of Glacier Fluctuations in the North Atlantic Area". Speakers: Mr. M. M. Sweeting, Mr. C. W. M Swithinbank and others.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Lawrence Bragg, F.R.S.: "Models of Metal Structure".

Saturday, November 20

Nutrition Society (in the Clinical Lecture Theatre, Middlesex Hospital Medical School, Mortimer Street, London, W.1), at 10.15 a.m.—Symposium on "The National Food Survey of Great Britain".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Sir Harry Luke: "Easter Island".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Analytical Chemist (with an appropriate university degree or Associate of the Royal Institute of Chemistry, and preferably with some experience in an industrial laboratory) in the Central Laboratory—The Chief Personnel Officer, North Western Gas Board (Liverpool Group), Radiant House, Bold Street, Liverpool 1 (November 17).

Lecturer (with a university degree in engineering, some industrial experience, and preferably some teaching experience) in Mechanical Engineering—The Principal, Dudley and Staffordshire Technical College, Dudley (November 19).

Assistant Lecturer or Lecturer in the Department of Inorganic and Physical Chemistry—The Registrar, The University, Liverpool (November 20).

Senior Lecturer (with high academic qualifications and able to teach to special (honours) degree standard) in the Mathematics Department—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (November 20).

Junior Assistant Physicist (with a good honours degree and preferably some postgraduate experience) in the Department of Physics Applied to Medicine, Middlesex Hospital Medical School—The Secretary, Barnato Joel Laboratories, The Middlesex Hospital, London, W.1 (November 22).

Lecturer (with a good honours degree) in Geography, at the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (November 22).

Scientific Officer (with an honours degree in bacteriology, or an honours degree in science with a diploma in bacteriology, and preferably with a good knowledge of chemistry) in the Bacteriology Department—The Secretary, Hannah Dairy Research Institute, Kirkhill, Ayr (November 22).

Assistant (with a degree or equivalent in mathematics or statistics) for numerical and computational work arising from mathematical and statistical research on animal and plant populations—The Establishment Officer, The Nature Conservancy, 19 Belgrave Square, London, S.W.1 (November 27).

Principal Scientific Officer (with a first- or second-class honours degree or equivalent in mechanical engineering or physics, with appropriate experimental experience and some knowledge of thermodynamics) in the Naval Air Department of the Royal Aircraft Establishment, Bedford, to take charge of a section responsible for research, development and testing of catapults for launching aircraft from carriers—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.728/54A (November 27).

Assistant Lecturer in Pure Mathematics—The Registrar, University College of North Staffordshire, Keele, Staffs (November 30)

Lecturer, Grade II (preferably with industrial experience in the development of electrical machinery) in Electrical Engineering—The Registrar, The University, Birmingham 15 (November 30).

Senior Lecturer (graduate of a British university, with appropriate qualifications and experience) in Physics, at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Hong Kong, November 30)

Technical Advisory Officers (with a degree in botany or agriculture or a recognized diploma in agriculture or horticulture, and preferably with a leaning towards, and experience in, grassland work), for work which involves the giving of advice to affiliated clubs and subscribing organizations on all matters concerning the establishment and maintenance of turf—The Director, Sports Turf Research Institute, St. Ives Research Station, Bingley, Yorkshire (November 30).

Research Assistant (preferably with experience of electronics) in the Department of Physics—The Registrar, University College Singleton Park, Swansea (December 1).

Research Officer (with a university honours degree in science or in veterinary science with physiology as a major subject, or equivalent qualifications) at the Sheep Biology Laboratory, Division of Animal Health and Production, Commonwealth Scientific and Industrial Research Organization, Great Western Highway, Prospect, New South Wales, Australia, to undertake investigations on the endocrinology of wool growth—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 205/55 (December 4)

Senior Research Officer or Research Officer (with a university degree in veterinary science or equivalent qualification and postgraduate research experience) at the MacMaster Animal Health Laboratory, Division of Animal Health and Production, Commonwealth Scientific and Industrial Research Organization, Parramatta Road, Glebe, New South Wales, to undertake investigations on parasitological problems of sheep, with particular reference to the control of liver fluke and to the development of and use of new anthelmintics—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 202/98 (December 4).

Chair of History and Philosophy of Science tenable at University College—The Academic Registrar, University of London, Senate House, London, W.C.1 (December 6)

Chair of Philosophy—The Secretary, The University, College Gate, St. Andrews (December 6).

Associate Professor (with a degree in science, engineering or metallurgy, with postgraduate research experience, and preferably some industrial experience) of Metallurgy, at Newcastle University College, New South Wales, Australia—The Agent General for New South Wales, 56–57 Strand, London, W.C.2 (December 21).

Assistant Experimental Officer (with at least H.S.C. or equivalent, and preferably conversant with radioactive measuring instruments) to assist in the development of prototype nucleonic instruments (Ref. 244/WGB/2); an Experimental Officer and an Assistant Experimental Officer (with at least H.S.C. in physics or equivalent) for research into the physical and mechanical properties of radioactive metals and alloys (Ref. 273/WGB/2); and an Experimental Officer (with at least H.S.C. and a knowledge of physical chemistry and some experience in chemical engineering) to assist in development work on high explosives on the plant scale and in the laboratory—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting appropriate Ref. No.

Assistant Lecturer (graduate, with experience in teaching or in industry) in the School of Physics—The Registrar, College of Technology and Commerce, Leicester

Engineers and Physicists (with an appropriate first- or second-class honours degree or equivalent high professional attainments), in Royal Naval Scientific Service Experimental Establishments in the London, Portsmouth, Weymouth and Gloucestershire areas, and in Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.246/52A.

Honours Graduate for work involving a study of continuous fermentation on laboratory scale, and operation of small continuous culture plant—The Director, Antibiotics Research Station, 4 Hilton Road, Clevedon, Somerset.

Lecturer (with a good honours degree) in Electrical Engineering—The Secretary, Royal Technical College, George Street, Glasgow, C.1.

Mathematical Physicists (with a first- or second-class honours degree in mathematics or physics, together with some years appropriate postgraduate experience) for work in one of the following fields: astrophysics, fluid dynamics, nuclear physics or statistics—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 283/WGB/34.

Principal Scientific Officer (with a first- or second-class honours degree or equivalent in physics or engineering, and with considerable research and development experience in the instrument-electronics field or related system of engineering in the aircraft industry) at the Royal Aircraft Establishment, Farnborough, Hants, to take charge of a project group responsible for the development in industry of a guided weapon—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.306/54A.

Technical Assistant (graduate chemist) in the Patents Division—The Secretary, National Research Development Corporation, 1 Tilney Street, London, W.1.

THE UNIVERSITY OF UTOPIA

ALTHOUGH the discussion on the adaptation of a university to the changing needs of the community, arranged on September 2 by Section L (Education) at the British Association meeting at Oxford, was somewhat circumscribed, the Section was well advised to raise a topic which has such general interest. The shortage of science teachers is only one particularly acute aspect of that general question. The expansion of technical and of technological education, and the supply of scientists and technologists as well as of administrators for industry and elsewhere, are other aspects of the adaptation of a university to the needs of the community. The means we adopt for meeting these changing needs, and the distribution of the nation's resources at the various levels of educational activity, depend in turn on our view of the true functions of a university and the stage at which and the means by which admitted defects are best corrected.

The British Association discussion was unrepresentative. Of its two papers, one, by Mr. J. T. Christie, principal of Jesus College, Oxford, was concerned with Oxford itself, as representing the two ancient universities. The other paper, read by Prof. F. A. Vick, in Prof. W. A. C. Stewart's absence, although concerned with what Sir Richard Livingstone characterized as the most interesting experiment in university education in Britain, could not claim, by itself, to be representative of the modern university. It was limited to a factual account of the University College of North Staffordshire, and an appreciation of the experience of its first four years, particularly with the fundamental idea of the exploratory foundation year. This is, of course, an attempt to broaden the range of academic courses, to meet the plea for more breadth which the Duke of Edinburgh, for example, voiced with such eloquence on his installation as chancellor of the University of Edinburgh. The important argument is, however, how and where the foundation for a broader education should be laid. The Duke of Edinburgh argued soundly that if narrowness begins in school it cannot be cured at the university or anywhere else. It is in school, he suggested, and not at the university, that the budding scientist should be helped, for example, to develop a taste for music and the arts, and the young historian an understanding and reverence for science. Clearly Sir Edward Appleton does not stand alone in deploring as a retrograde step the removal of two such broadening subjects as history and geography as higher subjects from the entrance examination to Scottish universities.

Even if, however, we accept it as a proper responsibility for the university to encourage general study, apart from providing a rich diversity of all the activities which make up civilized life, it should still be remembered that, as the title alone of a broadsheet, "The Keele Experiment" (No. 372 ; October 18, 1954), issued by Political and Economic Planning reminds us, the University College of North Staffordshire is only an experiment. For all the interest taken in this experiment in the Dominions and in the United States, as well as in Britain itself, it is far too early to form any opinion on the new type of university education provided at Keele. In ten or so years time, when there will have been more than a thousand graduates, it will be easier to see how the experiment is working. Meanwhile, this experimental basis makes a university college of no more than four hundred students completely unrepresentative of the 30,000 students in other modern English universities and university colleges, excluding London; moreover, there was no contribution to the British Association discussion from the University of London or the universities of Wales and Scotland.

Mr. Christie, however, not only fairly represented the nearly 15,000 students at Oxford and Cambridge, but also raised some significant points. His paper left no doubt that both universities are changing under the impact of social as well as of economic conditions, and that their growing dependence on State aid and the wider range of society from which their students are drawn involve problems and even threats to the performance of their functions. Mr. Christie is satisfied that there is at Oxford still the right balance of arts and sciences to provide a background for that wider informal education which is conducted by discussion and by living together in college. He indicated, however, that the university is increasingly concerned to meet the needs here of those students who come from homes with few books or cultural amenities, and that in these days an ancient university has perhaps a special responsibility for the preservation of the habits of civilized intercourse, and the ideas of knowledge for its own sake and education for leisure.

Such ideas are liable to come under pressure both from the demands of the State and from those of the individual who looks upon a university as being purely a means of training for a career. A university, Mr. Christie agreed, in a sense is always vocational; but once we admit that its essential task is to train men and women for the community and in the numbers the community requires for particular purposes, we are exposed to a danger of directed education which threatens the whole idea of the pursuit of knowledge for its own sake. Mr. Christie firmly maintained that something more than the vocational idea is an essential element in the university ideal; but although he indicated clearly enough the danger that the social climate may debase the idea of a university, he did not in this paper attempt to formulate any clear conception of the function and purpose of a university.

A valuable contribution to that end is to be found in Dr. R. M. Hutchins's "The University of Utopia"[*], and in the Sir George Watson Lectures on "The Idea of an American University" which he has since delivered in Britain. Although Dr. Hutchins's criticism is directed at the university as it exists in the United States, much that he writes about the dangers of specialization, of State control and of social and political conformity has its bearing on problems confronting universities in Britain to-day. The conception of the university and its functions in the world to-day which he embodies in the description of the ideal university of Utopia is no less stimulating and provocative in the British context than in that of the United States. Dr. Hutchins asks the right questions, and although we may not always in Britain give the same answers as are given in the United States, they are questions to which answers must be found before we can wisely decide how far the expansion of university or technological education should proceed, the right balance of studies in the universities, the distribution of resources between university, technological and technical education, the function of the universities in adult education and whether the attempt to secure greater breadth should be pursued in the schools or afterwards.

What stands out most clearly from the discussion at Oxford, and also in the pictures which Dr. Hutchins gives both of the American university and of the University of Utopia, is the dependence of the university on the character of the society it serves. The greatest weaknesses of the American university stem, in Dr. Hutchins's view, from weaknesses in American society. Mr. Christie similarly pointed to weaknesses in the ancient universities of Britain which arise fundamentally from social conditions in the homes from which their students are drawn. It is not primarily a matter of financial dependence, though that can also play a part—and on it Dr. Hutchins makes some caustic comments. The real case for university autonomy lies, in his view, on the proposition that societies require centres of independent thought and criticism if they are to progress or even to survive.

The conception of a university as a centre of independent thought is, of course, not new; nor is it inconsistent with the conception of the university as a place of vocational training, at least in so far as sovereign place is given to the educational rather than to the professional end. The conception of the university as a centre of independent thought, dedicated to the pursuit of truth by untrammelled thinking, by following the argument wherever it may lead, and meeting the critical encounter of other judgments, is implicit in the view of the functions of a university as expressed by the University Grants Committee nearly twenty years ago. Unless the universities are so dedicated and independent, they cannot stimulate and train their students "at least to think, and to think strenuously about the great issues of right and wrong, of liberty and government, on which, both for the individual and for the community, a balanced judgment is essential to a rational life".

Discussions on industry and the universities in recent years have made it unmistakable that such qualities of independent thinking are among those which industry looks for in recruiting university graduates, and the need for them in the Departments of State from Ministerial rank downwards has been forcibly demonstrated of late. The question of the true purpose of a university bears closely both on the extent and the character of the vocational or professional education which a university should give. Dr. Hutchins, in depicting the University of Utopia, seems to over-stress one aspect; but it should be remembered that he puts the right question first and also that in his Utopia much education or professional training of university status, in the sense in which the word is commonly used, is carried out in other institutions.

---

[*] The University of Utopia. By Robert M. Hutchins. (Charles R. Walgreen Foundation Lectures.) Pp. ix+103. (Chicago: Univ. of Chicago Press; London: Camb. Univ. Press, 1953.) 19s. net.

If vocational education deflects the university from its primary function as a centre of independent thought, the imaginative pursuit of learning and the quality of its vocational education will soon suffer. The University of Utopia rests on the assumption that there should be somewhere in the State an organization the purpose of which is to produce men who can think most profoundly about the most important intellectual issues; and Dr. Hutchins, pointing out that this implies that unpopular opinions are likely to be heard in the university from time to time, insists that such a university can only function if its nature and purpose are clearly understood by the community. No one who has followed the post-war discussions on university development or the expansion of higher technological education in Britain can fail to appreciate the soundness of this argument.

Dr. Hutchins goes on to suggest that the first step towards clarifying the popular conception of the purpose and functions of a university is to exclude from the university those activities which are not proper to it, which prevent understanding of the function of the universities, and which create confusion in regard to it. There may be little danger in Great Britain of eccentricities in regard to degree subjects, of which Dr. Hutchins gives fresh examples; but some of the proposals in regard to technological education go far enough in that direction to prevent any self-righteousness. What is important to remember is that, as Mr. N. G. Fisher pointed out at a recent conference of the British Association for Commercial and Industrial Education, the universities are already subjected to pressures from students and the parents of students towards vocational education, or even training, which could easily divert them from their true function. Unless that task of educating public opinion as to the true function of the university is undertaken vigorously and continuously, there is real danger, not so much that insufficient public funds will be forthcoming for the universities, as that the universities will find their teaching so circumscribed by vocational demands that it is conceived solely in terms of qualification for a career.

Fortunately, in Great Britain the universities are still in a key position to influence the social pressures that shape them, and Dr. Hutchins's book is primarily of value as a reminder of the urgency and importance of that responsibility. The task is indeed being undertaken. Sir Hector Hetherington's Essex Hall Lecture last year on "The Social Function of the University", like the reports of the University Grants Committee, are important contributions to that end, and it is worth noting that Sir Hector essentially endorses Dr. Hutchins's criteria as to the fitness of a subject for university study, or indeed for study at any level in an educational system: it must have intellectual content in its own right.

The point is worth emphasizing again, because it bears closely on the expansion of technological education also and on the balance between that and technical education. Clear ideas as to the proper content of university and technological education are essential if standards are to be maintained and our limited resources of teachers of science and technology deployed to provide for the output of scientists and technologists which the interests of Britain manifestly demand. The recent conferences on industry and the universities arranged by the Federation of British Industries have fully endorsed the view set forth in the last quinquennial report from the University Grants Committee, namely, that a university has not fully discharged its obligations unless its teaching is so designed as to ensure for all of its students who use their opportunities the chance to become, in Mill's words, "capable and cultivated human beings". Nevertheless, much more could be done by both parties to those conferences, and probably also by the Parliamentary and Scientific Committee, to put such ideas before Parliament and the public in general.

MICHAEL SERVETUS, 1511–53

Michael Servetus

Humanist and Martyr. By John F. Fulton. (With a bibliography of his works and census of known copies, by Madeline E. Stanton.) Pp. 98+9 plates. (New York: Herbert Reichner, 1953.) 8.50 dollars.

Michael Servetus

A Translation of his Geographical, Medical and Astrological Writings, with Introductions and Notes. By Charles Donald O'Malley. (Memoirs of the American Philosophical Society, Vol. 34.) Pp. 208+5 plates. (Philadelphia: American Philosophical Society, 1953.) 3 dollars.

JUST over four hundred years ago, Michael Servetus, condemned by Calvin, was burned at the stake in Geneva because he had dared to regard the historical interpretation of Jesus as infinitely superior to the complex subtleties of the Trinity. But this original definition of the Unitarian belief is not the chief reason for the high place of Servetus in history. He is remembered to-day mainly as the discoverer of the pulmonary circulation. His anatomical knowledge was sound, and he not only discovered that the blood circulates through the lungs in passing from the right to the left side of the heart, but also he came very near to the anticipation of Harvey's discovery made in the following century, when he explained that "vital spirit is then transferred from the left ventricle of the heart into the arteries of the whole body". Those remarkable statements attracted little notice at the time, because they were buried in the pages of the famous theological work, "Christianismi Restitutio", of which only three copies escaped destruction, and which, as Dr. C. D. O'Malley states, is the book which helped to bring about its author's death but has also helped to keep his name alive.

This mixture of theology and physiology in a single work may appear strange to us in our own time of extreme specialism. We must recall the fact that the medieval mind was at least versatile, and that Servetus was more interested in the blood-stream as a vehicle for the soul or *spiritus*, rather than as a physiological phenomenon. The fact that an Arabic writer of the thirteenth century, Ibn an-Nafis, whose manuscript was discovered only in 1924, had grasped the idea of the lesser circulation, does not detract from the achievement of Servetus, who was probably unaware of this work. The question of priority is further complicated by the accounts of the pulmonary circulation, by another Spaniard, Valverde, in 1556, and by a successor of Vesalius at Padua, Realdo Colombo, in his "De re anatomica", 1559. Those descriptions may well have been based upon the work of Servetus. Remembering his fate, the writers would hesitate to acknowledge the source of their information. At all events, the discovery remained obscure for long, and Harvey, seventy-five years later, appears to have had no knowledge of Servetus.

All these questions are concisely discussed by Prof. J. F. Fulton in his admirable biography of Servetus. After due reference to the investigations of Galen and of Vesalius, as a background, Prof. Fulton discusses the career of Michael Servetus, on the basis of the comparatively slender evidence available. Studying at the universities of Saragossa and Toulouse, he led a wandering life, and we find him at Bologna and Basle, at Lyons and Paris, and lastly, to his undoing, at Geneva. His first two tracts on the errors of the Trinity, "De Trinitatis Erroribus" (1532) and "Dialogorum de Trinitate" (1533), shocked Catholic and reformer alike; so much so that for the next twenty-five years Servetus assumed the name Michael Villanovanus, after the town of Villanueva in Spain where he had spent his early years.

In Lyons, Servetus translated Ptolemy's "Geography", which had been a standard work since the second century, and added original material of his own. His estimate of the Scots is worth quoting: "They are brave in war, very enduring of hunger and lack of sleep, of pleasing manners, but very lacking in sophistication. They rejoice in falsehood, nor do they cultivate peace as the English". Dr. O'Malley has given us excellent translations of this and other works of Servetus. Among them is "In Leonardum Fuchsium Apologia" (1536), in which Servetus champions Symphorien Champier of Lyons against the equally eminent physician Leonard Fuchs of Tubingen: their quarrel relating to the differing views of the Greeks and the Arabists, whether the new disease of syphilis was the *lichen* of Greek times, and sundry other matters.

Servetus's work on the syrups (a generic term for many of the remedies of his time), "Syruporum Universa Ratio", dated 1537, accounts for more than half the pages of Dr. O'Malley's book. It deals extensively with Galen's views on digestion, or concoction, as he called it, and on the routine use of purgatives as an aid to health—a procedure followed for centuries and not altogether extinct to-day. The Discourse in Favour of Astrology, "Disceptatio pro Astrologia" (1538), shows that Servetus retained the medieval outlook. His translation of the Bible, issued in 1542, probably led Servetus to restate more strongly than ever his heretical views regarding the Trinity, in his "Christianismi Restitutio" of 1553, which led so swiftly to his death as a martyr.

The original editions of the works of Servetus are extremely rare, and the preparation of translations, and of a bibliography, must surely have been very hard tasks. Those tasks have been well performed, and Miss Stanton deserves special praise for a bibliography which presented such unusual problems. These two books, which have been reviewed together, do not conflict in any sense, but each is the complement of the other. Together, they form a worthy memorial to a gallant and tragic spirit who deserves to be remembered four hundred years after his untimely death.

Douglas Guthrie

THE RIGHT TO DISSENT

Freedom, Loyalty, Dissent

By Prof. Henry Steele Commager. Pp. x+99. (London: Oxford University Press, 1954.) 8s. 6d. net.

LIKE Prof. A. Macbeath's plea for heretics at the British Association meeting in Belfast, the five essays collected in this volume develop the pragmatic argument that the right to dissent, even to be wrong, is an imperative necessity for a society in which science or any other creative activity is to flourish. The several themes—the necessity of freedom and of experimentation, free enterprise in ideas, guilt by association, who is loyal to America ?—are linked by this argument, that to preserve and encourage the exercise of freedom of inquiry, investigation, dissent and association, whether in education, science, literature or politics, is not an abstraction or luxury but a first condition of the survival of a democratic society as it is understood in Great Britain or the United States.

Prof. H. S. Commager's essays are addressed to an American audience, but quite apart from the evidence they afford that there are those in the United States itself who have a national audience and are not afraid to attack McCarthyism, his refreshing defence of intellectual freedom will appeal to all scientists who welcomed Prof. Macbeath's forthright words. In the accents of Mill rather than of Burke, he argues for the encouragement of the experimental attitude in science, because "if we create a climate of opinion in which scientists fear to be bold and original or if we require that they work only on projects that appear to be of immediate importance to us, we shall end up with scientists and scientific knowledge inadequate to the tasks that we impose upon them". Similarly, he argues that without freedom to experiment in politics, the political system will prove inadequate to the demands now made upon it. Without freedom for the scientist, the scholar, the critic, without the open mind in politics, in economics, in international relations, even in the realm of morals we forfeit alike security and the ability to adapt ourselves to new demands or new situations.

Prof. Commager, no more than Prof. Macbeath, is not advocating license. He recognizes that there must be limits on liberty, as there are limits on authority. Here again, the appeal is to the practical, not to the constitutional or to natural rights. To draw the line between the exercise of freedom and the limitations on freedom is one of the most delicate tasks of statesmanship and philosophy, and the governing factor he suggests is that no society can afford the cumulative costs of the intimidation of thoughtful and critical men and women. Security and progress are most likely to be achieved by a government which scrupulously protects and encourages complete freedom of thought, expression, communication, investigation and criticism. "A society that attempts to put education and science and scholarship in strait jackets will find that in strait jackets there can be no movement and that the result will be intellectual atrophy."

But Prof. Commager does not merely attack. When he touches, for example, on the questions of loyalty and the right of association, he raises issues that run far wider than the activities of McCarthy and which call for examination in a British context. The divorce or gap between membership and responsibility is already embarrassing scientific societies in Britain, and the implications of Prof. Commager's comment here merit examination. What he writes further about the way in which a blow at the principle and practice of voluntary association endangers the working machinery of democracy is supported by the whole argument of such a book as C. D. McIver's "The Ramparts We Defend", or the late Lord Lindsay of Birker's writings on democracy. Once the notion that joining an organization may be dangerous is firmly established, all organizations or institutions will be affected, whether of science, the professions, education, the arts or government itself, and a fatal blow may well be dealt to the functioning of those communal groups in which, in the complexities of to-day, individual men and women increasingly find opportunity for self-expression and for influencing events. Gratitude for a lucid restatement of the case for freedom of thought and a courageous attack on illiberalism should not be allowed to lead to the challenge of this book being ignored, or prevent an examination of exactly why the pragmatic tradition proved too weak to inhibit the growth of McCarthyism. Why this retreat from reason ? R. BRIGHTMAN

DETERMINATION OF CRYSTAL STRUCTURES

The Determination of Crystal Structures

By Dr. H. Lipson and Dr. W. Cochran. (The Crystalline State—Vol. 3.) Pp. ix+345+9 plates. (London: G. Bell and Sons, Ltd., 1953.) 50s. net.

SOME crystals seem most reluctant to give up their secrets. Though they are easily persuaded to yield more than enough data for their structures to be found, yet with a perversity inherent in their very nature, they scramble it first. The problem thus presented to the X-ray crystallographer resembles a jig-saw puzzle of several hundred pieces each bearing the same pattern on both its sides, and he must decide where each piece belongs in the picture and which way up it should go—often indeed without any clear idea of what the picture will prove to be. This ambiguity, which conceals such valuable prizes, has called forth great ingenuity, especially during the past few years. The attack has been systematized, and this book is a manual of both strategy and tactics, the first, in fact, to be devoted so fully and exclusively to that end.

The authors presuppose that a set of intensities has been measured on some arbitrary scale, and address themselves to the interpretation, or the finding of a structure which not only makes chemical sense, but is also capable of refinement. This occupies four chapters. The refinement and the precision ultimately achieved are discussed in another chapter, while the first four are devoted to a detailed discussion of all the principles and computational routines which comprise the main tools of the structure analyst.

The volume lacks nothing of the high standards of scholarship and presentation that distinguished its predecessors, but its compilation has presented the authors with problems peculiar to this volume. Like painters busy on the portrait of an active child, they found their subject just would not sit still. Of the 309 references, 143 relate to the years 1948 and onward (three of them in 1953), which are the years in which the book was prepared. This does not imply a neglect of earlier publications, but is a fair indication of the spate of work with which the authors had to contend. One would have been satisfied if they had only harvested this prolific crop. They have, however, done much more. The crop has been threshed and assessed, and at every turn valuable comments are given from their own experience on the best ways of handling each different method: these are the tactics which so rarely find their way into the original literature.

Both the authors are well known to crystallographers as pioneers who have contributed substantially to this subject, and as writers with a clear and easy style. Their practical outlook has not prevented them from including results which, although of no practical utility, have thrown valuable light on the subject. They have effected valuable economies by referring freely to Vols. 1 and 2 of the series and to the "International Tables". In only one place (in the early part of Chapter 2) do they seem a little undecided about the level of experience expected from the reader, for though on one hand the symbols (graphic and Hermann–Mauguin) for screws and glides are introduced without explanation, yet it was apparently deemed necessary to deduce *ab initio* the systematic absences they produce. Very great care has obviously been taken in the proof-reading, for very few misprints have been found and, of these, only one, a tangle of signs in the last equation on p. 80 and the first on p. 81, involve more than a momentary interruption of the reading.

The publishers, too, share in the credit for this book in two ways especially. First, it was decided to make the book comprehensive up to the end of 1952, but the rapid and continued development of the subject could have made the book largely out of date at the time of its appearance had the publishers not co-operated so well. Secondly, the authors use some innovations in the numbering of figures and equations and in their combined author-index and bibliography. These are, as the authors hoped, a great help to all who will wish frequently to consult the book, but it is evident that it involved both the authors and the publishers in considerable extra work. They must be congratulated that the experiment was made and was not allowed to delay the appearance of the book.

The volume is freely illustrated and will stand up to all the hard wear it is sure to get. Its price is reasonable if judged by modern standards of size and quality, but is very reasonable if judged by its usefulness and the wealth of material that has been packed into it. It is certain that this book will stimulate yet more work, so that it will require considerable expansion in its second edition. It is at present small enough to permit of such expansion, and the foundation already laid should be ample to carry it. Anyway, by the time the second edition appears, these copies will be due for honourable retirement; they are not likely to get much peace until then.

D. ROGERS

THE SYNCHRONOUS INDUCTION MOTOR

The Synchronous Induction Motor
By J. Griffin. Pp. 136. (London: Macdonald and Co. (Publishers), Ltd., 1954.) 18s. net.

ROTATING electromagnetic machines form a family of machines in which a field-producing element and a current-carrying element react in such a way as either to convert electrical into mechanical energy or vice versa. The different methods used to activate the elements give rise to the various types of machines and include the use of direct or of alternating current and, in the latter case, of supply by direct connexion or by induction. Most types maintain the same methods during running as during starting, and their behaviour under both conditions of operation can be understood from consideration of the basic characteristics of their individual types. But the synchronous induction motor embodies the characteristics of two fundamentally different types: one, the induction motor, actuates both elements from a single source; the other, the synchronous motor, uses two different sources to energize the elements. One difficulty presented to the student of this machine is in understanding how the transition from induction motor to synchronous motor occurs, and how it will affect the machine in its ability to pull into synchronism; and another is in appreciating the effect of direct current flowing in a polyphase winding and producing a magnetic field.

The author of this book treats these problems in a practical manner, and his review is materially helped by the co-operation of manufacturers, who have provided the material for the many plates with which the book is illustrated. Mr. L. H. A. Carr, in a foreword, points out the value of a book which explains to utilization engineers the properties of a machine permitting power-factor control and to teachers the theory of the cylindrical rotor type of synchronous machine.

In the introduction the author pays tribute to the Swedish inventor Danielson, who brought out the motor in 1900, and gives in an appendix a translation of an article in *Elektrotechnische Zeitschrift* (December 26, 1901) by Danielson. A chapter is given to methods of starting, and some important points are made such as the necessity on the grounds of temperature rise to limit horse-power output demands when over-exciting the machine for power-factor correction. There are useful chapters on synchronous motor theory and on the economics of power-factor correction, and the effect of first cost is well discussed. Overload capacity, automatic control and electrodynamic braking are adequately and simply described. The merits of making the rotor carry the primary winding are well brought out, and general limits of the method as to voltage and output are stated.

Secondary windings are described generally and include double three-phase star, open delta, unsymmetrical three-phase star, two-phase with single-phase excited; and the general theory concludes with a comprehensive treatment of the problem of the exciting current and its calculation. A brief chapter on the salient-pole synchronous induction motor is interpolated, presumably for purposes of comparison of performance, and the book concludes with details and examples of general construction. There are a useful bibliography and a good index.

H. M. CLARKE

A MODERN VIEW OF INORGANIC CHEMISTRY

Comprehensive Inorganic Chemistry
Edited by Prof. M. Cannon Sneed, Prof. J. Lewis Maynard, and Prof. Robert C. Brasted. Vol. 1: Principles of Atomic and Molecular Structure. By W. N. Lipscomb. Theoretical and Applied Nuclear Chemistry. By P. R. O'Connor. The Actinide Series. By G. T. Seaborg. Pp. xi+232. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1953.) 35s. net.

THERE can be many plans for the writing of books. In this case different authors have contributed separate sections, each of which is, in its own way, complete within itself and relatively independent of the others. In such circumstances, one might ask whether the choice of articles is the best and whether any given topic has been developed in the most suitable manner.

The introductory section to the first volume of this series, by William N. Lipscomb, deals with principles of atomic and molecular structure. Discussion is restricted to extra-nuclear properties such as electronic structure, chemical bonds and structures of molecules and crystals. The material is very well presented in a space of eighty pages, an impression of completeness having been achieved by strict adherence to the main theme. The second chapter, on theoretical and applied nuclear chemistry, by P. R. O'Connor, also eighty pages in length, includes a useful account of elementary particles, nuclear structure and radioactivity, followed by a discussion of methods of radioisotope production and applications to chemical problems. The last chapter, on the actinide series, has been written by Prof. G. T. Seaborg. It is, of course, authoritative, and extremely well presented, although perhaps written with rather more bias towards the radiochemical point of view than is necessary in a volume on inorganic chemistry.

This criticism is one which might be levelled at the volume as a whole. The development of atomic energy has undoubtedly led to a great development in radiochemistry, and it is a good thing that this aspect of inorganic chemistry should be well to the fore in a modern treatise. If it seems to have been overdone in this instance, it is probably because the volume has the character of a collection of independent review articles rather than that of a really cohesive treatise. On the other hand, it must not be denied that the system has its merits, particularly when the standard of the individual articles is as good as in the present instance. The book should, therefore, be well received by students and research workers alike.

R. SPENCE

Infrared Absorption Spectra of Steroids

An Atlas. By Konrad Dobriner, E. R. Katzenellenbogen and R. Norman Jones. Pp. xlv+299. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1953.) 11.50 dollars.

USUALLY infra-red spectra are duplicated or printed separately as in the American Petroleum Institute spectra of hydrocarbons, but occasional attempts have been made to provide collected spectra in book form. Nothing comparable with the present atlas in quality of spectra or wide range of comparatively inaccessible compounds has, however, previously appeared. At first sight, the atlas seems highly priced, but since 306 spectra are presented the cost only works out to about 3*d*. each, which compares favourably with, say, American Petroleum Institute spectra. It is obviously a great convenience to have spectra in book form, neatly classified, and it is probable that in years to come every department of organic chemistry will possess rows of volumes similar to this.

Each spectrum in the atlas has been obtained under the supervision of the authors with 1–5 mgm. of material dissolved in carbon disulphide, carbon tetrachloride or chloroform. By using a double-beam instrument with a variable-length cell in the comparison beam, the solvent absorption has been practically eliminated. The spectral regions covered are 1,800–1,580, 1,480–1,300, 1,400–650 and (in twelve cases) 3,700–2,800 cm.$^{-1}$. Even with steroids differing only in some minor point of structure, the spectra are distinct although the spectral differences may be quite small.

This work was started as an aid to cancer research by the late Dr. K. Dobriner. It is a matter of great regret that the death of this investigator has removed a distinguished pioneer from an important field, but this well-laid foundation will certainly be used to great advantage by others. A. E. MARTIN

Time Counts

The Story of the Calendar. By Harold Watkins. Pp. xi+274. (London: Neville Spearman, Ltd., 1954.) 15*s*. net.

THE first portion of this book gives a brief history of the calendar up to the time of the introduction of the Gregorian Calendar into Great Britain in 1752. If there is a second edition, the first chapter, which is based on the unacceptable theories of Hoerbiger and Bellamy, should be omitted.

The main part of the book is concerned with the various proposals that have been made for the reform of the Gregorian Calendar and, in particular, with the advantages of the scheme advocated by the World Calendar Association. A proposal in favour of the adoption of the World Calendar has recently been brought before the Economic and Social Council of the United Nations Organization by the Government of India, which is concerned with rectifying the complicated calendar situation in India, where many different calendars are in use; India would like, at the same time, to remove the illogicalities and inconveniences of the present calendar.

The Economic and Social Council at its meeting in Geneva at the end of July decided, by a unanimous vote, to refer the question of the reform of the calendar for study by the governments of the world, with the view of its discussion at the nineteenth session of the Council next year.

The fixing of the date of Easter is a separate question. The inconveniences of the date of Easter wandering over a period of thirty-five days are widely felt, and the adoption of the World Calendar would greatly facilitate the fixing of the date of Easter. H. S. J.

Lower Tertiary Foraminifera of the Qatar Peninsula

By Alan Hilder Smout. Pp. ix+96+15 plates. (London: British Museum (Natural History).) 45*s*.

THE title of this monograph obscures the fact that it is essentially a study of the Rotaliidea, almost half the contents being devoted to an account of the structure and evolution of the group, the remainder to systematics. Dr. A. H. Smout demonstrates that the rotaliid test is formed by "instars" of successive laminæ, each of which totally encloses the whole of the previously formed test, so that in *Nummulites*, for example, the test is constructed from a series of "chinese-box laminæ" and not, as previously thought, from a spiral chevron of shell material.

Evidence from physiology and fossil morphology, influenced by D'Arcy Thompson's "Growth and Form", is synthesized into a persuasive morphogenical argument. Conviction that direct adaptations are possible as a result of physical difficulties imposed on the sarcode by increase in size of the test leads to a limited Neo-Lamarckian interpretation, the author, however, being prepared to allow normal genetical factors to fix and translate the acquired character into the earlier stages of succeeding ontogenies. The systematics are concerned with a revised classification of the Rotaliidea; the erection of a new superfamily, the Discorbidea; and a description of rotaliids and a few associated forms from borings in north-east Arabia, including three new genera, *Dictyokathina*, *Kathina* and *Daviesina*, seventeen new species, and two new varieties.

The monograph, which is beautifully printed and illustrated, deserves to be much more widely read than might be expected from its generalized title, since the views expressed are fundamental to adequate appreciation of the structure and morphological evolution of the larger foraminifera.

The Geology of South Africa

By Dr. Alex. L. du Toit. Edited and prepared for publication by Dr. S. H. Haughton. Third edition, revised and enlarged. Pp. xiv+611+41 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1954.) 63*s*. net.

THE late Alexander du Toit's "Geology of South Africa" first appeared in 1926 (*Nature*, 119, 665; 1927) and was followed by a second edition in 1939. Du Toit himself had almost finished the text of this new revised and enlarged edition at the time of his death in February 1948. The task of completing the revision, with the aid of certain notes left among the author's papers, and the preparation of the manuscript for the press were placed in the capable hands of Dr. S. H. Haughton.

While the text has been left essentially in the state in which the author prepared it, attention has been directed, by means of footnotes, to later work by South African geologists in which views have been expressed, particularly on problems of correlation, that differ materially from those of the author. The coloured geological map that accompanies the volume has been completely revised and redrawn under Dr. Haughton's supervision. Geologists everywhere will welcome the new edition of this standard and authoritative work.

THE SPECIES SPECIFICITY OF MYOGLOBIN

By Dr. J. C. KENDREW and Dr. R. G. PARRISH*
Medical Research Council Unit for the Study of the Molecular Structure of Biological Systems, Cavendish Laboratory, Cambridge
AND
Prof. J. R. MARRACK and Dr. E. S. ORLANS†
Department of Pathology, University of Cambridge

Crystallographic Aspects

MYOGLOBIN is in many ways a very suitable protein for X-ray crystallographic studies, but has hitherto been scarcely a convenient one, since it is difficult to crystallize when obtained from the more common domestic animals. During a survey of less easily available animals—in particular the whales—we have found a number of new crystal forms of myoglobin, some of them very readily prepared. The main purpose of this survey was to discover crystals suitable for detailed study by X-ray diffraction, and accounts of such studies will be published elsewhere; however, the distribution of these forms among the species we have examined is also of interest from the point of view of species specificity and zoological relationship, and in the light of immunological studies described in the second part of this paper.

In searching for promising sources of myoglobin, we have mainly investigated aquatic mammals, and birds which spend a good deal of time under water; the skeletal muscles of such animals often contain so much myoglobin that they are almost black in colour. We have found that whales (especially the sperm whale, *Physeter catodon*), seals and penguins are particularly rich sources; on the other hand, a specimen of dugong meat (kindly sent to us from Ceylon by Mr. J. W. S. Pringle) was very pale and contained little myoglobin.

The procedure used for extracting and purifying the myoglobin was a modification of that described by Morgan[1], Theorell and de Duve[2], and Schmid[3]; it consists in essence of extracting the myoglobin from minced tissue with ice-cold water, and removing other proteins by treatment with lead acetate and by repeated recrystallization from ammonium sulphate and from concentrated phosphate buffer. Crystallization may be effected by salting-out from either of the latter media.

By methods of this kind, varying in detail from species to species, we have found some dozen crystal forms of myoglobin, all of which have been studied by X-ray methods. Of these (see Table 1) only the following have been previously described: horse myoglobin (type *C*), see Kendrew[4] and Kendrew and Trotter[5]; finback whale myoglobin (type *F*), see Schmid[3] and Kendrew[6]. Blue whale crystals of type *E* were first prepared by Dr. J. Keilin in 1951 and examined crystallographically by one of us[7]. The crystals of tortoise and carp myoglobins were first prepared by Hamoir[8] and Renard[9], and those used by us for X-ray analysis were made from material supplied by them. Besides all these, the myoglobins of a number of species, including cow, man, ass, mule and pig, have been crystallized by Rossi-Fanelli, Theorell, Roche, Vieil, Drabkin and their associates; we have omitted these from present consideration since in no case have they been studied by X-ray methods.

We find that several different types of crystal may sometimes be derived from the same species of animal (see Table 2); often different forms are obtained according to the salt used for precipitation (for example, sperm whale gives type *A* in ammonium sulphate, type *B* in phosphate), while sometimes different derivatives of the protein crystallize in different forms (for example, myoglobin of gentoo penguin; as metmyoglobin in phosphate this gives type *G*, as imidazole-myoglobin it gives type *H*. In ammonium sulphate the met-compound refused to crystallize, while the imidazole derivative gave

Table 1. Types of Myoglobin Crystal

Type	Principal source	Symmetry	Space group	Mol./cell	Cell dimensions (wet) a	b	c	β
A	Sperm whale* (from ammon. sulph.)	Monoclinic	$P2_1$	2	64·6 A.	31·1 A.	34·8 A.	105·5°
B	Sperm whale (from phosphate)	Orthorhombic	$P2_12_12_1$	4	48·9	40·2	79·3	
C i	Horse†	Monoclinic	$P2_1$	2	57·3	30·8	57·0	112°
	Seal‡	Monoclinic	$P2_1$	2	57·7	29·6	57·1	112°
ii	Seal§	Monoclinic face-cent.	$A2$	4	57·7	29·6	106·2	102°
iii	Horse	Monoclinic ψ-orthorh.	$P2_1$	4	57·0	30·8	106·0	91°
D	Blue whale	Orthorhombic	$P2_12_12_1$	4	33·9	60·4	76·6	
E	Blue whale	Orthorhombic	$P2_12_12_1$	12–16	144·5	37·7	107·5	
F	Finback whale	Orthorhombic	$P2_12_12$	4	97·4	39·8	42·5	
G	Gentoo penguin	Face-cent. orthorhombic	$C222_1$	8	48·3	80·2	78·5	
H	Gentoo penguin (imidazole deriv., phosphate)	Orthorhombic	$P2_12_12_1$	4	106·4	39·1	45·3	
I	Gentoo penguin (imidazole deriv., ammon. sulph.)	Orthorhombic	$P2_12_12_1$ (?)	4	94·5	38·3	43·5	
J	Carp	Orthorhombic	$P2_12_12_1$	4	55·0	46·5	51·7	

* A related lattice was obtained from tortoise (*Testudo graeca*), with space group $P2_1$ and lattice dimensions a = 64·3, b = 30·2, c = 36·4 A., β = 105°; the distribution of intensities is fairly similar to that of type *A*. A shrinkage stage of this lattice was observed.
† In addition, one shrinkage stage.
‡ In addition, one swelling stage.
§ In addition, three shrinkage stages.

Cyprinus carpio (carp)	*J*	0	

* Crystals obtained, but too small for X-ray analysis.
† Crystals of this form rarely obtained.

crystals of type *I*). On the other hand, we sometimes obtained virtually the same crystal form from two or more different species; by this we mean that the lattice dimensions were nearly identical, and the intensities of corresponding X-ray reflexions difficult to distinguish. In some cases (for example, type *A*) the resemblance is very close indeed; in others there may be appreciable changes in cell dimensions (for example, in type *C*, where horse myoglobin crystals have $b = 30 \cdot 8$ A. and seal crystals have $b = 29 \cdot 6$ A.), though the general resemblance is unmistakable. Tortoise myoglobin provides an example of a more distant relationship, its crystals showing a definite resemblance to crystals of type *A* but nothing approaching an identity; tortoise myoglobin crystals stand in the same sort of relationship to type *A* as would a shrinkage stage, if one were known. Crystals of type *C* form a most interesting group; as has been indicated in a recent paper[4], horse myoglobin generally forms pseudo-orthorhombic crystals having four molecules in the unit cell, this arrangement being derived by inversion of alternate sheets of molecules from a rare monoclinic form (two molecules/cell) obtained on one occasion only[4]. In the common seal as well we obtained two related forms: by crystallization from phosphate a monoclinic 2-molecule form closely resembling monoclinic horse myoglobin, and from ammonium sulphate a new face-centred 4-molecule monoclinic form derived from this by simple translation of alternate sheets of molecules in the *b*-direction instead of by inversion. The Patterson projections of these forms confirm these relationships, which will be discussed in detail elsewhere.

The close resemblances between certain crystal forms of myoglobins from different species provide justification for a comparative study of myoglobin structure using different types of crystal. The myoglobin molecules in sperm whale, in porpoise, and in four *Balaenoptera* species, all of them crystallizing in type *A*, must resemble one another extremely closely; indeed, from the still rather crude point of view of the X-ray analyst, one can certainly regard them as identical. These facts, taken together with the polymorphism of myoglobin from sperm whale and porpoise (types *A* and *B*), of blue whale (types *A*, *D* and *E*), and of finback whale (types *A* and *F*), mean that from this point of view we are entitled to assume the virtual identity of the myoglobin molecules present in types *A*, *B*, *D*, *E* and *F*, and to make comparative studies of these forms. Type *C* (horse and seal), types *G*, *H*, *I* (gentoo penguin) and type *J* (carp) still lie outside this system. In the absence of complete chemical analyses we cannot do more than guess at reasons for the slight but observable intensity differences between the diffraction patterns of, for example, type *A* crystals from different species; they are, however, of a magnitude which would be accounted for by differences of one or a few side-chains in the molecule. In monoclinic sperm whale myoglobin, differences of the same order of magnitude have been produced artificially by attaching an imidazole molecule to the hæm group prior to crystallization; but even so small an alteration in the molecule can sometimes produce a more extensive change in crystal habit. Thus in orthorhombic sperm whale myoglobin the imidazole derivative gives intensities so much changed from normal that one must assume an appreciable change in crystal packing, although the lattice constants are very slightly affected, if at all: in the gentoo penguin, as has already been pointed out, a complete change in crystal form is induced by the attachment of imidazole.

Immunological Aspects

The cross-reactions of the myoglobins of various species with antisera against sperm whale and seal (*Phoca vitulina*) myoglobins were studied by three methods:

(*a*) *Ouchterlony's method*[14]. Cup *A* (Fig. 1), which was cut out of a layer of agar in a Petri dish, was filled with antiserum; cup *B* with a solution of the homologous myoglobin (*M*) and cup *C* with a solution of another myoglobin (*M'*); the concentrations of the myoglobin solutions were about 0·02 per cent. Antigen and antibody diffuse into the agar and form a precipitate where they meet; the precipitate is soluble in excess of antigen, so that the band of

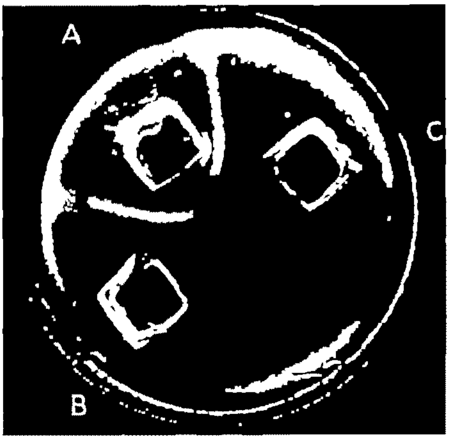

Fig. 1. Reactions of sperm whale and finback whale myoglobins with a solution of γ-globulin prepared from a pool of antisera against sperm whale myoglobin, demonstrated by Ouchterlony's method: *A*, γ-globulin solution; *B*, sperm whale myoglobin; *C*, finback whale myoglobin

precipitate is limited on the antigen side. If M and M' are identical, excess of antigen sufficient to inhibit precipitation is reached at the same place by antigen diffusing from B and from C: the left- and right-hand bands are continuous. If M' is similar to M and will precipitate some, but not all, of the antibody in the antiserum, excess with respect to the M'-antibody reaction will be reached before excess with respect to the M-antibody reaction: the bands will not be continuous (as in Fig. 1). The more similar M' is to M the more nearly will the right-hand and left-hand bands be continuous. If M' is so unlike M that it forms no precipitate with the anti-M serum, no band of precipitate will form on the right. Estimates of the degree of similarity of myoglobins of other species to sperm whale myoglobin, assessed in this way, are given in column *a* of Table 2.

(*b*) The maximum amount of precipitate formed by M' with anti-M serum can be used as another criterion of the immunological similarity of M' to M. The amounts of precipitates formed by various myoglobins with anti-sera against sperm whale myoglobin (expressed as percentages of the maximum precipitate formed by sperm whale myoglobin with the antisera) are given in column *b* of Table 2. The antisera used were from the same rabbit, bled on October 8 (1953) and March 12 (1954), after a further course of injections. The figures in brackets were obtained with the second sample of antiserum: it appears that, as is usual after more prolonged immunization, the second antiserum cross-reacted with heterologous antigens more strongly than the first.

(*c*) The antisera, particularly those against seal myoglobin, were rather weak. Concentrated solutions of γ-globulin were therefore prepared from the antisera, and rough visual estimates were made of the amounts of precipitate formed by the various myoglobins with these solutions; and the rates of flocculation of the anti-sperm whale myoglobin γ-globulin with various myoglobins (at optimum proportions) were compared.

As judged by these three criteria, the myoglobins may be classified into five groups, ranging from those in group (1) which cross-react very strongly with sperm whale myoglobin, to those in group (5) which do not cross-react at all: (1) porpoise, sei whale, and lesser rorqual; (2) humpback and blue whale; (3) dolphin and finback whale; (4) seal; (5) tortoise, horse, penguin and carp. (There is little distinction between groups (1) and (2).)

When sei whale or porpoise myoglobin was used in cup C in Ouchterlony's method, with certain samples of sperm whale antiserum in cup A, two distinct bands appeared on the right-hand side; on the left the separation of the bands are less definite. This is evidence that these antisera contain antibodies against two antigens in the sperm whale myoglobin and in the sei whale and porpoise myoglobins. The ratios of the two antigens in the sperm whale myoglobin to the two antibodies in the antisera were such that the points at which excesses of both antigens were reached almost coincided, whereas the ratio of the two antigens in the sei whale and in the porpoise myoglobins was slightly different. When the γ-globulin solution prepared from pooled antisera was used in cup A and a solution of finback whale myoglobin in cup C, three distinct bands were formed on the right-hand side (Fig. 1)—evidence of the presence in the γ-globulin of antibodies against three antigens. These results suggest that myoglobin as prepared from tissues by rigorous methods (which include repeated recrystallizations—in the case of the sperm whale antigen five times from ammonium sulphate and twice from phosphate) consists of more than one component: the same conclusion has previously been reached from electrophoretic studies[3].

The antiserum against seal (*Phoca vitulina*) myoglobin cross-reacted with myoglobins of other members of the same order (*Zalophus californianus*, *Mirounga peonina*, and another seal of unknown species), but not with horse myoglobin.

Kesztyus and Várterész[11] obtained antisera against horse, ox, dog, pig and cat myoglobins; each formed a precipitate with myoglobin of the homologous species and not with the heterologous antigens. None of these species is as closely related as the members of the Cetacea. Comparable studies are those of Heidelberger and Landsteiner[12] and of Hektoen and his colleagues[13–15] on hæmoglobins; cross-reactions were found between horse, donkey and mule hæmoglobins, between human and rhesus hæmoglobins and between ox, sheep, goat and yak hæmoglobins.

Relationships of the Myoglobins

The range of purified myoglobins available from various animal species is now wide, and this protein would probably lend itself well to detailed investigations of species specificity. It is unfortunate that at present complete amino-acid composition data are available only for horse[16] and finback whale[17] myoglobins, and the molecular weight has been determined only for horse (there is, however, reason for supposing that the molecular weight of blue whale myoglobin is also about 17,000[18]; furthermore, all the X-ray data are consistent with this being the value in every species so far examined). But even without other data, the distribution of crystal forms shows features of interest. Thus type *A* crystals are widespread among whale myoglobins, and indeed they have been made from almost every species of whale the myoglobin of which has so far been crystallized; but it is remarkable that although the form is predominant in both the main groups—the toothed and the whalebone whales—there are two members of the whalebone genus *Balaenoptera* in which type *A* has been encountered only very rarely (myoglobin from *B. musculus* and *B. physalus* almost always crystallizes in type *D*, *E* or *F*), although these species are morphologically much more closely related to *B. borealis* and *B. acutorostrata* than are the toothed whales *Physeter catodon* and *Phocaena phocaena*—in all four of which type *A* is the predominant form.

This distribution of crystal forms is in accord with the immunological results which, as we have seen, also suggest a relatively closer resemblance between the myoglobins of certain whalebone whales and of the toothed whales, and a relatively greater dissimilarity between that of *B. physalus* and those of other members of the genus *Balaenoptera*, than would have been anticipated from the conventional morphological classification. On the other hand, myoglobins which have similar crystal forms are not necessarily similar immunologically; horse myoglobin did not form a precipitate with antiserum against the myoglobin of the seal *Phoca vitulina*, although both myoglobins give type *C* crystals.

Such chemical information as is available is not inconsistent with the findings of the present investigation. Terminal amino-groups have been shown (by the fluoro-dinitrobenzene method) to be present to the extent of one per 17,000 molecular weight units in each of the four species of myoglobin so far investigated. In finback whale[17] and sperm whale[19] the terminal residue is valine; in horse[20] it is glycine, and one of us (E. S. O.) has recently found that it is also glycine in the seal *Phoca vitulina*. So far as it goes, the correlation is satisfactory; but it is clear that at present the relationships can only be incompletely grasped. One might, for example, have anticipated a cross-reaction between horse and seal myoglobins, and between those of sperm whale and tortoise, in conformity with the chemical and crystallographic relations. There is evidently a need for wider studies using chemical as well as immunological and crystallographic techniques, if a deeper insight is to be gained into the molecular basis of species specificity and morphological classification.

It appears from the ratio of antibody to antigen in the precipitates that one molecule of myoglobin can combine with three of antibody; thus there must be three combining groups on the myoglobin molecule. Some indication of the nature of these groups might be gained by comparative chemical studies; these could be directed in the first instance towards pairs of species such as, on one hand, the horse and the common grey seal, the myoglobins of which crystallize in closely related forms giving very similar diffraction patterns but do not cross-react; and, on the other hand, sperm and sei whale myoglobins, the crystals of which stand in a similarly close relation to one another, but which cross-react very strongly. As has been indicated, the chemical differences required to account for the differences in diffraction pattern might amount to one or two amino-acid residues; but they could as well be differences of sequence as differences of overall composition, so the chemical procedures required to detect them might be very laborious.

We are grateful to many individuals and institutions for assistance in obtaining samples of meat; among them are the Low Temperature Research Station at Cambridge (especially Dr. R. G. Sharp), Zoological Society (London), Dr. F. C. Fraser, of the British Museum (Natural History), Royal Scottish Museum, Hector Whaling, Ltd. (especially Mr. H. W. Symons), Pacific Steam Navigation Co., National Institute of Oceanography (especially Mr. R. Clarke), Prof. C. Monge, of the University of Lima (Peru), Prof. G. Hamoir, of the University of Liège (Belgium), Prof. R. J. Harrison, of the London Hospital Medical School. One of us (J. R. M.) gratefully acknowledges financial assistance from the Nuffield Foundation.

ELECTRONIC BAND STRUCTURE OF SOLIDS

THE growing importance which government scientific establishments now attach to the theory of the electronic band structure of solids is shown by the holding of a conference on this subject at the Radar Research Establishment in Malvern during September 27–28. Besides members of the Establishment, there were representatives present from Harwell and Baldock, as well as from most of the universities in Great Britain.

It is now about twenty-five years since the idea of a band structure for the energy-levels of electrons in a crystal lattice was put forward by Bloch and others; and during this period, apart from certain stimulating but controversial ideas of Linus Pauling in the United States, this concept has dominated all theoretical discussions of metals, particularly of electrical conductivity and related effects. According to this approximation, the valence, or conduction, electrons are treated as moving, more-or-less independently of each other, in the electrostatic field produced by the positive nuclei and the average Coulomb potential of the various electrons. These electrons are allotted to energy-levels, which lie in bands, often—but not always—separated from each other, having forbidden energies between them. The density distribution $N(E)$ of these energies is fundamental for almost all later applications.

One of the earliest calculations of these energy-levels is the so-called cell model. In this model, we divide the space around each atom into cells, and within each cell (sometimes replaced by an effective sphere for convenience in manipulation) we solve the Schrodinger wave equation, using the potential field for an isolated atom, but replacing atomic boundary conditions by appropriate boundary conditions for the cell. But recently certain serious difficulties have become apparent. Thus, we have good reason for believing that over the greater part of the atomic cell —or polyhedron—the absolute magnitude of the wave function ψ is nearly constant, showing fluctuations only in the immediate vicinity of the nuclei. Now, the representation of an almost constant function within a polyhedron in terms of atom-like s,p,d, functions with correct boundary conditions is not easy; and it has been found necessary to use high-energy atomic orbitals. A further difficulty was pointed out by N. H. March (Sheffield), who showed, from a Thomas–Fermi statistical approximation in a diamond-type structure, that it is not adequate to use the spherically symmetrical atomic potential. Instead, the perturbations due to incipient chemical bonds affect the symmetry both of the potential and the wave functions by introducing higher-order angular terms.

More recently, the cell model has been replaced by an alternative, in which the potential is taken as constant over the metal, excluding a suitable spherical region around each nucleus. In this latter region it has the atomic value. Where the potential is constant, the wave function is that of a plane wave. But near the nuclei, ψ deviates considerably from this form. This method is referred to as the augmented plane-wave method. Dr. D. J. Howarth (Malvern) has extended this treatment, and, particularly for the important case of copper, has shown how, by combining two or more plane waves (equivalent to each other in the reciprocal lattice space), a rapid convergence is obtained. It was previously supposed that too many terms would be needed to make this method usable. A further variant of this treatment has been introduced by R. S. Leigh (Harwell), who found that it is possible to work with wave functions within and without the nuclear spheres, which are not continuous at the boundary and the gradients of which are also discontinuous. This 'shocking' disregard of conventional usage seems to work much better than might have been expected.

Another alternative to the cell-model type of approach is the tight-binding method, familiar to chemists as the molecular orbital approximation. Dr. G. C. Fletcher (Exeter) described the application of this method to the 3*d* electrons in nickel, and the possibility of inferring ferromagnetic anisotropy factors. Dr. E. P. Wohlfarth (Imperial College of Science and Technology, London) showed how, if we accept the idea of an energy band, we may use experimental ferromagnetic curves to infer the shape of these bands. Dr. R. Barrie (Services Electronics Research Laboratory, Baldock) showed similar uses of thermoelectric power data, particularly in relation to semiconductors such as gallium–arsenic or indium–antimony, where the energy gap between bands is relatively small. Lattice scattering was discussed by J. M. Radcliffe (Malvern), and Dr. S. L. Altmann (Oxford) gave a general discussion of the way in which the non-localized orbitals may be replaced by an equivalent set of localized, or Wannier, functions.

So far we have accepted the fundamental concept of an energy band; but this is now under serious scrutiny. For the electrons affect each other, and there are large exchange forces between electrons of similar spin, which are different from those between electrons of opposite spin. If this is a significant difference, the basis on which calculations are made is entirely changed. It is believed that just this situation does arise in antiferromagnetism, where electrons of one type of spin tend to collect on certain sites, whereas electrons of the other type congregate around the alternate sites. Clearly the form of the effective one-electron potential is crucial. Dr. G. G. Hall (Cambridge) discussed this on the basis of the Hartree–Fock type of wave function, showing among other things that the presence of an exchange force should lead to a different potential for occupied and unoccupied states. The relevance of this for all discussion of X-ray absorption spectra, in which an electron is lifted from a lower (atomic) level to one of the previously unoccupied conduction levels, is obvious.

A second criticism of the simple band theory came from R. J. Elliott (Harwell), who showed that the spin-orbit coupling of the conduction electrons, almost always neglected in calculations of this kind, is not really negligible, and can easily amount to 0·4 eV. in particular cases. In addition, Dr. S. Raimes (Imperial College, London) indicated that the recent theory of Bohm and Pines, in which long-range correlation of electrons is taken account of in terms of so-called plasma oscillations, also affects the shape of the $N(E)$ curve. Not only does it give a far more satisfactory shape than the Hartree–Fock approximation, but it also reduces the calculated band-width, as seems to be required to agree with experiment, and also leads to the possibility of a 'tail' in the soft X-ray emission curve. Such tails exist, and have been a source of considerable perplexity to the experimentalist who tries to interpret them in terms of a conventional band concept. This explanation may easily provide a way out of the difficulty.

A final criticism of the one-electron picture came from J. Hawgood (Newcastle), who showed how to apply the molecular theories of configurational interaction to a simplified 'linear' metal. The number of configurations to be considered is enormous, reminiscent of the number of canonical structures in organic chemistry. But sufficient progress has been achieved to suggest that this is a hopeful line of approach.

The foregoing account should make it clear that no strikingly new theories have been put forward. But at long last, it looks as if we are beginning to understand both the limitations of any band theory of the electrons in a metal, and also the type of numerical and algebraic technique that is likely to prove most effective in handling the problem on the assumption that a band model is legitimate.

C. A. COULSON

ABRAHAM DE MOIVRE (1667–1754)

TWO hundred years ago, on November 27, 1754, the death occurred in London of the Huguenot refugee, Abraham de Moivre, whose name is best known from his theorem in analytical trigonometry. But perhaps more important were his contributions to the theory of probability, which, according to Todhunter, owes more to him than to any other mathematician, with the sole exception of Laplace.

The son of a surgeon, de Moivre was born on May 26, 1667, in Vitry, France. He was at first educated by the Christian Brothers, but at the age of eleven entered the Protestant University of Sedan. His studies were continued at Saumur and Paris, but were suddenly interrupted in 1685 by the revocation of the Edict of Nantes and his seclusion in a priory. On his release in 1688 he went to London, with a letter of recommendation to the Earl of Devonshire, at whose house he heard of Newton's "Principia". In 1692 he met Halley and soon afterwards Newton, who esteemed him very highly, and in his later years used to reply to inquiries about mathematics and the "Principia": "Go to Mr. de Moivre; he knows these things better than I do". De Moivre contributed a paper on fluxions to the Royal Society in 1695 and was elected a Fellow in 1697. In 1712 the Royal Society appointed him to the committee to report on the Newton–Leibniz controversy.

De Moivre's first publication on probability was "De Mensura Sortis" (1711), which extended de Montmort's essay on games of chance. The more important "Doctrine of Chances" (1718) dealt with the probability of a compound event and with many particular problems. De Moivre was second only to Halley as a founder of the theory of life contingencies, and his "Annuities on Lives" (1725), which was much used by actuaries, ran into several editions. The "Miscellanea Analytica" (1730) included analytical trigonometry, recurring series, problems of chance, and analysis applied to astronomy. It contained something equivalent to 'De Moivre's theorem', though the usual form of this theorem was not explicitly stated, and there was also 'De Moivre's property of the circle'. These trigonometrical results were the development of the work of R. Cotes. Many copies of the "Miscellanea Analytica" contain a supplement which ends with a table of fourteen-place logarithms of factorials. But a second supplement, dated 1733, is so rare that it was unknown to most authorities until described by Karl Pearson[1]; this contained the first treatment of the probability integral and essentially of the normal curve, long before the discussions by Laplace and Gauss. De Moivre also discovered what is usually known as Stirling's theorem, an approximate formula for the factorial of a large number; he communicated the result to Stirling, who then obtained an alternative proof and a slightly improved form. What is now known as Bernoulli's theorem was only partially due to Bernoulli, for it was completed by de Moivre.

The "Miscellanea Analytica" brought fame to its author and his election as a member of the Berlin Academy. Unfortunately, in spite of de Moivre's many influential admirers, the fact that he was of French birth prevented him from attaining any satisfactory appointment, either in Britain or Germany. He supported himself by private tuition and lectures, and in his old age earned a precarious living at Slaughter's Coffee House by solving problems on games of chance for its aristocratic frequenters. A few months before he died he was elected an associate of the Paris Academy of Sciences.

USE OF RADIOACTIVE ISOTOPES IN SMALL-MAMMAL ECOLOGY

By GILLIAN K. GODFREY
(Mrs. Crowcroft)
Zoological Society of London

MANY problems in animal population studies require for their solution knowledge of the range of movement of individuals. Repeated live-trapping of marked animals is the usual technique employed, though with birds and the larger mammals visual observation is often possible. The availability of a wide range of radioactive isotopes has enabled certain animals, especially insects, to be marked in a novel and efficient manner. Radioactive isotopes also promise to be of great value for obtaining direct information about the movements of a single individual.

The first recorded use of radioactive material in tracing the movements of an animal is by Tomes and Brian[1,2]. Female click beetles (*Agriotes*) were labelled with radium sulphate which was sandwiched between aluminium disks and fastened beneath the elytra. The beetles, which could be detected through three inches of soil, were located periodically with a Geiger–Muller counter. Daily movements were of the order of twelve inches. Certain other insect studies have involved the actual incorporation of the radioactive isotope into the tissues[3,4].

It is difficult to obtain information about the movements of small mammals as they are relatively mobile and carry out most of their activities in dense cover or below ground. It is known that live-trapping may produce both physiological and psychological effects, the former being seen in abnormal movements after release, and the latter in changed behaviour towards traps. By trapping a small mammal once only, attaching a radioactive source and following it about with a portable Geiger–Muller counter, it is possible to make a large number of observations without disturbing it further. Clearly, the size and habits of the species will determine whether or not this method is practicable: for example, it will not be applicable to the study of a large, highly mobile mammal like the fox.

The method was applied in 1949, however, to a study of the movements of the field vole (*Microtus agrestis*)[5]. A high-energy gamma source was required as the animals had to be detected through tall, dense grass (*Brachypodium*) and at times within shallow burrows. Cobalt-60 was chosen as it was available in a convenient form and had a long half-life (5·3 yr.). Each vole was labelled with 80–100 microcuries enclosed in a brass capsule which was soldered to a nickel leg-ring. The Geiger–Müller tube was mounted at the end of a 6-ft. rod, and as the source could be detected (through headphones) 3–4 ft. from the tube, the animal could be located at a distance of up to 12 ft. from the observer. By locating an individual at frequent intervals, a clear picture of its range of movement could be obtained. Labelling pregnant females with radioactive rings also proved a useful means of locating nests containing young[6]. Similar work has been attempted in America using meadow voles (*Microtus pennsylvanicus*) injected with beta-emitting radioactive phosphorus (L. Miller, personal communication). This method depends upon locating radioactive faeces, and appears to be of limited use for work on small mammals.

Radioactive labelling is currently being utilized in an ecological study of the mole (*Talpa europaea*), financed by the Nature Conservancy. A larger version of the ring used for *Microtus* is fitted around the base of the mole's tail, where it does not interfere with movements or digging. A source of 80 microcuries has proved sufficient in spite of soil absorption, for in the absence of tall vegetation the probe can be held immediately above the soil surface. Because of the mole's reputed sensitivity to vibration, a longer handle was fitted to the probe to enable the animal to be located at a greater distance.

The determination of the range of movement is only the first step in investigating the animal's relationship with its environment. The next step is clearly an attempt to find out how the individual obtains and expends its energy within its range. Live-trapping has proved an inadequate means of showing how the various parts of the range are used, and which areas within the perimeter are, in fact, not used at all. The way in which the animal distributes its activities in time must also be investigated. The ability to keep in almost continuous contact with a mole labelled with radioactive material means that, in this species at least, a start can be made on the simpler aspects of these problems. The animal's confinement within a discrete tunnel-system, much of which is visible on the surface, greatly simplifies the procedure of following it about. In practice, the actual paths taken as it moves about are marked with numbered pegs and afterwards recorded in detail. In this way a fairly accurate estimate of the linear distances moved in successive periods can be obtained. In addition to providing information about movements, long periods of continuous observation have revealed the nature of the mole's activity rhythm.

Before using radioactive labelling on a large scale, much thought must be given to possible immediate or long-term effects on the health and consequently the behaviour of the animals. Some of the theoretical considerations involved in estimating permissible dosages have been discussed by Griffin[7]. Where there is any danger of substantial loss of rings through predation, isotopes with a short half-life are obviously preferable. It is extremely unlikely, however, that predators will be affected when metal rings are used, as these are either rejected, regurgitated, or passed with the fæces. Nevertheless, the choice of a study area should take into account not only the range of the species being labelled, but also that of any possible predator. In the present work on moles, most of the rings have now been removed from the animals, which have shown no signs of ill-health.

A drawback of the technique is that it is impossible to distinguish between labelled individuals with overlapping ranges. Although this limits its use, there are many important population problems, which by their nature can only be studied at the individual level, and for these it promises to be of valuable application.

OBITUARIES

Dr. Philip Eggleton

By the death of Dr. Philip Eggleton on October 7 at the early age of fifty-two, medical science has lost one of its most versatile and original minds and the University of Edinburgh one of its most stimulating and popular teachers.

Eggleton received his undergraduate and post-graduate education at University College, London. After graduating with honours in chemistry in 1922, he joined the Department of Physiology and Biochemistry, where he studied for two years under Prof. E. H. Starling, Sir William Bayliss and Sir (then Prof.) Jack Drummond. In 1925, following a brief experience in industry, Eggleton returned to University College with a grant from the Medical Research Council to work on certain of the chemical aspects of muscular contraction under the direction of Prof. A. V. Hill. The following year he was awarded a Beit Memorial Fellowship to continue his work in this field.

During this period, Eggleton (with Grace P. Eggleton) carried out his now classical work on the phosphorus compounds in muscle, which culminated in the almost simultaneous discovery by Fiske and SubbaRow and by himself of creatine phosphate (phosphagen) and in the recognition of the importance of the latter in the chemistry of the contractile process. The part played by Eggleton in what has been termed "The Revolution in Muscle Physiology" (A. V. Hill) was a most distinguished one, and it was fitting that in 1931 he was awarded the Julius Mickle Fellowship by the University of London for the most outstanding research in medical science carried out in the University during the preceding five years.

In 1930 Eggleton went to Edinburgh as lecturer in biochemistry in the Department of Physiology, and in this capacity and as senior lecturer and reader served the University under no fewer than four professors of physiology. On three separate occasions he was acting-head of the Physiology Department for long periods. At Edinburgh, Eggleton developed his great potentialities as a teacher to the full, and soon became one of the most lucid and stimulating lecturers in the University. He also developed a remarkable facility for explaining scientific matters to the layman in vivid and readily understandable language; and, since he was convinced of the value of some knowledge of the aims and methods of science in the general education of everyone, it was natural for him to become actively interested in the popularization of science. In collaboration with Prof. W. O. Kermack, he wrote an excellent popular book, "The Stuff We Are Made Of", and for many years he acted as adviser to the B.B.C. in Scotland on scientific broadcasts. His own broadcast talks were models of what such talks should be.

An important part of Eggleton's duties at Edinburgh consisted in giving help and advice on many different chemical matters to his colleagues in the Physiology Department. Because of this, and also possibly because of his own inclinations, his interests in biochemistry and in science generally broadened very considerably. He extended his knowledge of mathematics, and latterly became interested in rheological problems in biology. Possibly his own career as a creative scientist might have been more spectacularly successful had he been less catholic in his interests and had he been less unselfish in his attitude to his colleagues. However, those who were closest to him know that he was always happiest when helping others.

During the Second World War, Eggleton collaborated in research in the Physiology Department under the direction of Prof. I. de B. Daly on phosgene poisoning on behalf of the Ministry of Supply, and on decompression problems on behalf of the Air Ministry. He joined the Edinburgh Gas Identification Service (Civil Defence) and became deputy district gas adviser for South-East Scotland.

Eggleton was a member of the Physiological Society, the Biochemical Society and the Society for Experimental Biology. He served on the committees of all three bodies. He was also a member of the Joint Committee on Rheology of the International Council of Scientific Unions, and he organized the First International Colloquium on Physiological Problems in Biology, which was held in Sweden in 1950.

G. F. Marrian

Dr. G. P. Douglas, O.B.E.

The death of Dr. G. P. Douglas on October 16 at his home at Camberley will be regretted by a wide circle of friends.

Born in 1892, he was educated at George Watson's College, Edinburgh, and graduated in 1914 from the University of Edinburgh with distinction in engineering. He served in the First World War and was awarded the M.C.; in July 1916 he was wounded, suffering the loss of his leg. In December of that year he joined the Royal Aircraft Factory (now Establishment), where he was concerned in the building and running of the 7-ft. wind tunnels which were to supplement the single 4-ft. tunnel that was then the sole equipment. In 1918 he became engineer in charge of the wind tunnels, and played a formative part in the development of model work at the Establishment. He had a genius for using simple means, lucidity as to the range of validity of these means, and a keen appreciation of the need for flexibility in method. During this period the 5-ft. and 24-ft. tunnels came into use.

In 1934 he became head of the Aerodynamics Department, of which the model work was one section. He played a big part in building up a strong department, more elaborate equipment, and enlarged field of work called for by the Second World War.

Dr. Douglas served on the council of the Royal Aeronautical Society during 1946–51, and for many years on the Aerodynamics Committee of the Aeronautical Research Council. He extended his contacts by attending the main international congresses on aerodynamics. He retired in March 1953. Though he would never allow the handicap of his lameness to keep him from clambering about aircraft, balloon shed roofs, ships, or anywhere else where his work lay, he had to pay for the effort involved by sacrificing many other activities. By the time of his retirement, he was over-strained by his unremitting devotion to duty.

To many of us, Dr. Douglas's greatest achievement lay in his personal influence in shaping the Department. He was honest to the core, humble as to his own attainments, and whole-heartedly pleased at the advance and achievement of the many distinguished people who served under him for various periods as young men. Under three ministries, he maintained to a very high measure the Aerodynamics Department as a place where scientists could grow up and develop their own type of ability, with the minimum of restrictive organization. F. B. BRADFIELD

Mr. Fred Lincoln

FRED LINCOLN, who has just died at the age of seventy-seven, must have been by far the most widely known laboratory assistant in the world. Almost all the leading physicists in the Commonwealth and many in other countries have worked in the Cavendish Laboratory at one time or another, and to all of them Lincoln was one of its main institutions. He joined the staff as a laboratory boy in 1893, and when I was a student Lincoln had already been the head assistant for many years. When I returned to Cambridge thirty years later as Cavendish professor, there was Lincoln in the same position and quite unchanged in appearance and energy. His fierce eye and even fiercer moustache still induced a very proper respect in the young research worker applying to him for apparatus or stores, and the kindness, humour and loyalty to the Laboratory, which had earned our admiration and affection, were the same as ever. When a presentation was made to him on the occasion of his retirement, contributions came from physicists all over the world, who will now be sad at the passing of a great figure and a warm friend. W. L. BRAGG

NEWS and VIEWS

Royal Society: Award of Royal Medals

H.M. THE QUEEN has been graciously pleased to approve recommendations made by the Council of the Royal Society for the award of the two Royal Medals for the current year as follows: Sir John Cockcroft, director of the Atomic Energy Research Establishment, Harwell, for his distinguished work on nuclear and atomic physics; Prof. H. A. Krebs, Whitley professor of biochemistry in the University of Oxford, for his distinguished contributions to biochemistry.

Chemistry at Aberdeen: Dr. G. M. Burnett

DR. G. M. BURNETT, at present lecturer in chemistry in the University of Birmingham, has been appointed to the chair of chemistry in the University of Aberdeen at the early age of thirty-three. Dr. Burnett succeeds Prof. R. M. Barrer, who has gone to the Imperial College of Science and Technology, London (see *Nature*, July 31, p. 205). Educated at Robert Gordon's College, Aberdeen, he graduated with first-class honours in chemistry at Aberdeen in 1943. Owing to war-time requirements, he became an assistant in the Physics Department at Aberdeen, with special responsibility for dealing with the supplies of radium for the hospitals in the north-east of Scotland. In his meagre spare time at that period, he started research on the problem of determining the absolute rate constants and radical concentration in liquid-phase free-radical polymerization reactions. He very quickly succeeded in obtaining an exact solution to this problem, and was in fact the first to do so. The extension and exploitation of this work have been his main preoccupation during his stay in Aberdeen and, since 1948, in Birmingham. Dr. Burnett has written many papers covering all aspects of this field, and these have culminated in the publication of a book on polymer reactions, which forms a landmark in describing and reviewing critically this important branch of polymer chemistry and reaction kinetics.

Pure Mathematics at Birmingham: Prof. C. A. Rogers

DR. C. A. ROGERS has been elected to the Mason professorship of pure mathematics in the University of Birmingham in succession to Prof. R. A. Rankin, who has gone to Glasgow (see *Nature*, April 3, p. 615). Dr. Rogers, who is thirty-three, graduated at University College, London, in 1941, and after war service in the Applied Ballistics Department (Ministry of Supply) returned to that College as a research student in 1945. He was appointed assistant lecturer in 1946 and lecturer in 1949. The title of reader in mathematics was conferred on him in 1953. Dr. Rogers was awarded a Commonwealth Fund Fellowship in 1949 and spent the session 1949–50 at the Institute for Advanced Study, Princeton. Dr. Rogers has published some forty papers, many of which are substantial memoirs. Most of his work has been on the theory of numbers, and in particular on the geometry of numbers. In 1947 he gave a new and simple proof (*Ann. Math.*, 48, 367; 1947) of the theorem of Minkowski and Hlawka, and this has proved to be the starting-point for much later work by himself and others. In a memoir published in *Acta Math.*, 82, 185 (1950), he applied to the geometry of numbers a new inequality obtained by solving an integral equation. Jointly with A. Dvoretzky he has solved an outstanding problem in the theory of Banach spaces (*Proc. U.S. Nat. Acad. Sci.*, 36, 192; 1950). Dr. Rogers's work has given him an international reputation as a pure mathematician, and he is also well known to many for his work in statistics and for his wide interests in science generally.

Veterinary Research in Mexico by the University of Pennsylvania

A CO-OPERATIVE research affiliation has been established between the School of Veterinary Medicine of the University of Pennsylvania and the Institute of Livestock Research (Institute de Investigaciones) at Palo Alto, near Mexico City, of the Mexican Government, and 18,000 dollars is being supplied by the United States Foreign Operations Administration to support the project. E. R. Squibb and Sons of Mexico, a subsidiary of the Olin Mathieson Chemical Corporation, New York, and E. R. Squibb and Sons, New York, are also participating and will assist in financing the undertaking. Prof. G. W. Rake, research professor of microbiology in the University of Pennsylvania, will direct the research work for the University at Palo Alto; before going to Philadelphia a year ago, he was director of the Squibb Medical Division for four years, and for twelve years previously headed the Microbiology Division of the Squibb Institute for Medical Research. Among the research workers from the Veterinary School in Philadelphia who are to be sent to Palo Alto will be Dr. Carlos Espana, who was born in Mexico and is a graduate of the University of Mexico. The Institute at Palo Alto, which was established in the 1940's mainly for combating foot-and-mouth disease, has four laboratory buildings, one large combination laboratory–administration building and thirty-six isolation units suitable for handling large farm animals; a main laboratory has been set aside for the Pennsylvanian workers and will be known as the Squibb–Mathieson Laboratory for Veterinary Research of the Ministry of Agriculture and Husbandry in Mexico and of the University of Pennsylvania. The first investigations to be made at this Laboratory will be one of the blood disease anaplasmosis, which is an infectious condition of the red corpuscles, and, later, studies will probably be made of shipping fever and brucellosis. The University of Pennsylvania plans to increase greatly the number of fellowships it offers for postgraduate training and, in particular, in return for the facilities at Palo Alto it will offer places for the training of Mexican veterinary workers and other scientists interested in infectious diseases affecting animals, with especial emphasis on those diseases transmissible to man. In conjunction with these new developments in Mexico, a dedicatory meeting was arranged in Palo Alto on November 17, and at the same time the annual conference of the Associated University of Pennsylvania Clubs was held in Mexico City.

Long Ashton Research Station: Report for 1953

THE annual report of the Agricultural and Horticultural Research Station, Long Ashton, for 1953 (from the Station at Long Ashton, Bristol; pp. 218+13 plates; 1954; 15s.) is of particular interest as it records the jubilee celebrations held in July of that year, and includes speeches made by Sir Thomas Dugdale, Lord Bledisloe, Mr. Christopher Norbury and Prof. T. Wallace on that occasion. The special jubilee lecture delivered by Lord Rothschild has already been published in the commemorative volume "Science and Fruit". The research work carried out during the year falls into five main categories: pomology, plant nutrition (including that under the Agricultural Research Council Unit for Micronutrients), plant pathology, cider and fruit juices, and domestic food preservation. Among the numerous subjects under investigation, mention may be made of a survey of perry pears in the West Midlands, carried out in view of the increased interest in this beverage. A number of varieties are described and illustrated, and an attempt has been made to sort out the confusion of synonyms. Spray application problems form the subject of a group of papers. A method is described for use in estimating the penetration of DDT into plant tissues, and the times, strengths and formulations for DDT and BHC given for control of apple and plum aphids and of BHC for apple sawfly. A combined DDT–BHC emulsion has also been prepared. Field trials have been carried out with airflow mist spraying, a technique aimed at reducing both costs and risk of crop damage. Though the method was successful with DDT and BHC emulsion against plum and apple aphid and apple sawfly, similar applications of lime sulphur failed to control red spider, woolly aphid or apple scab.

Geophysics in Canada during 1953

THE first volume of the series "Canadian Geophysical Bulletins", an annual review of activity in geophysical research and applied geophysics, published by the Associate Committee on Geodesy and Geophysics of the National Research Council of Canada, appeared in January 1947; the latest volume, Vol. 6, was published in December 1953, but has only comparatively recently been received here (pp. 73. Ottawa: National Research Council of Canada, 1953). It includes a bibliography of papers published during the year under review, either by Canadian workers in the field or by scientists from other countries, relating to Canadian problems. Short descriptions are given of nine papers on geodesy (including gravity), forty-two on seismology and the physics of the earth's interior, twelve on meteorology and hydrology, forty-nine on terrestrial magnetism and atmospheric electricity, and forty-two papers on oceanography. In December 1953, thirty-eight companies were known to be operating a total of about a hundred and fifty seismic prospecting parties in British Columbia, Alberta, Saskatchewan and Manitoba. Noteworthy is the publication by W. C. Gussow of the detailed geological, seismic and gravimetric studies of New Brunswick which were conducted for the Shell Oil Company (*Bull. Amer. Assoc. Pet. Geol.*, 37, 1713; 1953).

Catalogue of Polish Scientific Literature, 1945–49

VOL. 21 of the "Catalogue of Polish Scientific Literature" (pp. 441. Krakow: Polska Akademia Nauk) covers the years 1945–49 and bears the date of publication 1952, though it has only recently been received. It is the first to appear since that for the years 1931–34, but Vol. 20, covering the years 1935–39, will be published later. The entries are given alphabetically by authors in eleven main sections—mathematics, physics, astronomy, terrestrial sciences, botany, microbiology, zoology, archæology, geography, technology—with a miscellaneous section, and some sub-sections such as chemical technology. There is also an author index and a list of Polish periodicals from which entries are taken, with the abbreviations used, and which includes 254 items.

Science Masters' Association: Meeting in Newcastle upon Tyne

THE annual meeting of the Science Masters' Association will be held in King's College, Newcastle upon

Tyne, during December 28–31, the annual business meeting of the Association being on December 30 at 5.15 p.m. Dr. C. I. C. Bosanquet, rector of King's College, will deliver the presidential address to the Association on the evening of December 28, his subject being "In Praise of Natural Philosophy", and the Science and Citizenship Lecture will be given on the evening of the next day by Dr. Eric James, High Master of Manchester Grammar School. Besides the usual lectures in the morning on various scientific topics and informal visits to laboratories, there will be a discussion on the teaching of electricity, with special reference to M.K.S. units, on the morning of December 30, and another the next day on the teaching of science in secondary modern schools. As in the past, manufacturers and publishers who advertise in the *School Science Review* will be showing exhibits, and the usual members' exhibition of apparatus and teaching aids which members of the Association have found useful will also be held. The Northern Area Lighting Service Bureau of the Electric Lamp Manufacturers' Association has arranged to prepare an exhibition entitled "The Practical Aspects of Light and its Production", and the British Iron and Steel Federation will be showing some of its educational material. In the afternoons a number of excursions will be made to various works. Tickets are necessary for these visits and can be obtained from A. Hill, Hookergate Grammar School, Rowlands Gill, Co. Durham; they must be claimed by December 11. All other correspondence should be sent to the Annual Meeting Secretary, W. H. Dowland, 93 Westbourne Road, West Hartlepool, Co. Durham.

Physical Society : Annual Exhibition

The Physical Society's annual exhibition of scientific instruments and apparatus will be held in the New Hall of the Royal Horticultural Society, Westminster, during April 25–28, 1955. About a hundred and forty exhibitors are expected to take part, including the usual number of university departments and government establishments, and the exhibition will also include scientific books and journals. The handbook of the exhibition will be on the same lines as those of previous years, with a large advertisement section which is open to all firms with scientific interests, whether taking part in the exhibition or not. The change of venue from the Imperial College of Science and Technology, London, to the Royal Horticultural Society's New Hall will in no way change the character and purpose of the exhibition; the space in the New Hall is by its nature more compact than that which has hitherto been available, and it is hoped that this will help visitors to see the exhibits more advantageously in a shorter time. Further information can be obtained from the Honorary Exhibition Secretary, Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

Swedish Academy of Engineering Sciences : Awards

The Swedish Academy of Engineering Sciences has awarded four Gold Medals and its Brinell Medal for contributions in various scientific and technical fields. The Gold Medals have been awarded to the following: Mr. Erik Stemme, the principal scientific worker in a team that in three years has built the binary electronic computing machine BESK, the dielectric punched ribbon reader and certain details in its magnetic memory being the results of personal inventions by Mr. Stemme; Mr. Gunnar Jancke, for his role as a leading engineer in the designing and carrying out of a new network of high-tension electric cables which transmit current at 380,000 V. from the Lapland waterfalls to the central and southern parts of Sweden; Dr. Erik Bergstrand, for designing the geodimeter, an instrument for measuring geographical distances in terms of the time taken by light to traverse the distance, and which, incidentally, has been used in reverse to obtain an accurate measure of the velocity of light; and Mr. Olle Wernholm, for his work in perfecting electron accelerators. The Brinell Medal of the Academy goes, for the first time to a non-Swede, to Prof. John Chipman, of the Massachusetts Institute of Technology, for his achievements in the fields of metallurgy and metallography.

Announcements

Dr. H. J. Eysenck, reader in psychology with special reference to psychiatry in the Institute of Psychiatry, University of London, has been appointed to the University chair of psychology tenable at the Institute.

Applications are invited for the Drummond fellowship for research in nutrition, which will be awarded about March next year. The fellowship is worth £900 a year, normally tenable for two years, with up to £50 a year research expenses and £90 superannuation. Application forms, to be returned by January 15, and further information can be obtained from the Honorary Secretary, Drummond Trust, University College, Gower Street, London, W.C.1.

The Royal Society of New Zealand is offering a T. K. Sidey Summer-time Award, consisting of a bronze medal and prize of £100 (New Zealand currency), for scientific research on any kind of electromagnetic radiation (visible or invisible), including its relation to human welfare. Applications must be submitted by February 28, 1955. Further information can be obtained from the Secretary, Royal Society of New Zealand, Victoria University College, Wellington, W.1.

The Sabena International Prize, which was established in 1953 to mark the thirtieth anniversary of Sabena Belgian Airlines, is awarded in alternate years to an artist or research worker, less than thirty years of age and of either sex, who wishes to extend his or her general knowledge by travel-study in the Belgian Congo or the United States. The subject of this year's competition is "Aviation and Social Geography", and entries must be submitted by March 31. The prize is worth 75,000 Belgian francs (just over £500). The conditions of the competition and further information can be obtained from Sabena Belgian Airlines, Air Terminus, Brussels.

In an article discussing agricultural research in *Nature* of October 9, on p. 664 it is stated that "the Department of Scientific and Industrial Research . . . draws its revenue largely from industrial concerns". This is, of course, incorrect; the Department supports the research associations, and it is these associations which receive a major proportion of their revenues from industry.

In the advertisement supplement in *Nature* of November 13, p. ix, the telephone number of Teleonics (Communications), Ltd., is incorrect; we are asked to state that the correct number is Fulham 1534.

ARCHÆOLOGY IN THE LABORATORY

A CONFERENCE convened by the Council for British Archæology under the title "Archæology in the Laboratory" was held on April 9 in the rooms of the Society of Antiquaries of London, at Burlington House. The proceedings of the conference have only recently become available.

Dr. C. B. M. McBurney (University of Cambridge), in his introduction for the Council, explained that, since its formation in 1944 as the co-ordinating body for archæological research, the Council has been anxious to explore the various possible applications to archæology of the methods and results produced in other scientific fields. A Natural Sciences Panel was accordingly set up and had prepared the "Notes for the Guidance of Archæologists in regard to Expert Evidence" published in 1947. Not only are the "Notes" now out of date, but also the rapid acceleration of developments in science and technology has made it necessary to re-examine the whole matter with regard to both scope and organization. There is also the reverse aspect, not hitherto considered systematically, where the archæologist could provide the scientific research worker with valuable material in a context that could be precisely defined and is independently datable.

The Council had been considering a proposal, made earlier in the year by Mr. L. Biek (Ministry of Works), to establish a permanent Scientific Research Committee for Archæology. This was, in particular, to facilitate the flow of material sent from archæological excavations for expert examination and to collate the results, and generally to provide a clearing house for information and ideas of mutual value to archæologists and other scientists. The scheme was welcomed by archæologists and, at the suggestion of Sir Mortimer Wheeler (University of London), the Council had decided to invite scientists to give their views on the proposal. Dr. McBurney said he was asking if they considered it to be desirable and practicable, and what they felt about the reciprocal value, to themselves, of this type of work. He was further asking for details of recent advances, and for suggestions about improving and extending investigations as at present carried out, in the principal fields which had been selected for discussion, namely, petrology of stone implements and ceramics, building research, soil science, pollen analysis and other botanical examination, ecology, conchology, animal and human osteology, physical and chemical tests, and metallurgical and corrosion studies.

The following then gave their views: Mr. E. M. Jope (The Queen's University, Belfast), Prof. F. W. Shotton (University of Birmingham), Dr. F. S. Wallis (Bristol Museum), Mr. M. Davies (British Iron and Steel Research Association), Mr. H. Barker, Dr. F. C. Fraser and Dr. K. P. Oakley (British Museum), Dr. N. Davey and Dr. H. G. Midgley (Building Research Station, Department of Scientific and Industrial Research), Mr. R. M. Cook (Cambridge Museum of Classical Archæology), Dr. H. Godwin, Dr. S. K. Runcorn and Dr. J. O. Trevor (University of Cambridge), Mr. T. W. Farrer (Chemical Research Laboratory, Department of Scientific and Industrial Research), Dr. W. H. J. Vernon (recently of the Chemical Research Laboratory), Dr. F. Y. Henderson (Forest Products Research Laboratory, Department of Scientific and Industrial Research), Dr. P. A. Sabine (Geological Survey), Mr. C. F. M. Fryd (Department of the Government Chemist), Prof. R. D. Preston (University of Leeds), Dr. I. W. Cornwall, Prof. F. W. Jane and Prof. F. E. Zeuner (University of London), Mr. H. H. Coghlan (Newbury Museum), Dr. E. T. Hall (University of Oxford), and Dr. J. S. Weiner (Oxford University Museum).

With certain notable exceptions in the fields of metallurgical and palæomagnetic analysis, where more or less specific schemes are operating to less than capacity and samples are indeed welcome, it seems that there is a general lack of man-power if not, in most cases, of equipment. Nevertheless, work in all the other fields is proceeding well. Important advances have been made in applying the use of 'white' X-rays to the study of unknown materials. Pollen analysis has been expanded to include herbaceous plants and to give information about methods of husbandry. Full details were given about a 'general service' in carbon-14 dating, due to begin shortly. The possibility of typifying certain pottery on a physical basis (that is, by making thin sections, etc.) is being examined, and a tentative suggestion was made about relating changes in the submicroscopic structure of wooden remains to the duration of burial under certain conditions.

Although the principles are in most cases fairly well understood, methods of preparing specimens (for example, for charcoal analysis) are sometimes imperfect, or there may be a lack of suitable comparative material in certain specific respects (for example, for matching rocks or bones); both here and in fields not so limited (for example, in counting pollen grains), the work is extremely tedious and time-consuming.

The majority of speakers thus reluctantly, but firmly, refused to accept investigations which were unlikely to help in solving some major problem. Even in the relatively simpler work of chemical analysis, identifying wood, and analysing mortars, isolated queries are discouraged unless submitted through some recognized institution. In the case of mortar analysis, as also with samples for carbon-14 and palæomagnetic examination, correct and careful sampling is essential. Where, as in the majority of cases, this aspect is less important, it is at least necessary to know the context accurately and reliably, because results can only be interpreted in relation to 'neutral' associated material. On the other hand, with problems involving soil and pollen analysis, or the corrosion of metals, it is absolutely vital for the investigator to be present during excavation in order to evaluate all aspects of the site from his point of view and to take his own samples. Archæological evidence is of great importance to research in botany, geophysics and metallic corrosion, and can be of great value to building research, soil science, human osteology, and the submicroscopic study of wood.

The suggestions made for improvement fall into four general groups. First, more workers and more (suitably selected) material for analysis and reference constitute major requirements. Several speakers stressed that such work, in general, is not appropriately recognized or paid, and consequently the number of, say, geologists interested in archæological problems will always be very small. It would help if such small groups could meet regularly to discuss problems and progress. It was suggested that museum staff, in particular, should be approached with the view of interesting them more in this type of work. In Denmark, pollen analysts, petrologists and archæologists are successfully collaborating at the National Museum, and it was felt that the volume of such work in Britain would remain small until some similar scheme were put into operation.

It was further stressed that definite instructions should be issued to prevent the destruction or loss of valuable material (particularly botanical and osteological) and records (for example, of the preservation of buildings), and that these should be centrally stored and suitably catalogued; so that even if there should be no facilities for immediate examination, the material would be available later. Other suggestions included the preparation of sets of slides of petrological specimens from archæological finds, and organic-carbon assays (perhaps at university centres) to determine whether a sample is suitable for carbon-14 analysis. It is—as so very frequently in scientific work—most important to develop a battery of techniques for any one type of problem in order to obtain reliable results; thus no fewer than six methods were used in the recent investigation of the Piltdown mandible.

Secondly, it is important that archæologists should frame specific questions to accompany their material; this would considerably ease the investigators' burden, and serve to prevent friction and loss of time. In certain cases (for example, bones) excessive cleaning prior to dispatch from the site is undesirable.

Thirdly, it was obvious from all that had been said that the closest co-operation between archæologists and scientists at all stages is essential, not forgetting regular contact between, for example, the petrologists themselves who are engaged on archæological work.

Finally, this aspect becomes vital when (as in most cases) the problem has to be considered statistically. The examination of human bones can take on a wider significance only when its results can be related geographically. Only the archæologist can tell, in the last instance, which copper implements form a homogeneous series suitable for metallurgical analysis in attempting to trace the ores that have provided the metal; sometimes museum specimens of ores, selected on a different basis, may not include inferior material that might well have been used by early metal-workers.

In carbon-14 determinations, quite apart from the statistical errors due to equipment and method, structural differences between young and mature wood, and contamination both during and after burial may be expected to affect the results. A number of such 'rogues' have in fact been encountered, and single or even duplicate estimations may well be more misleading than helpful unless considered on a wider statistical basis. This calls for full and accurate publication of results, and the Council was urged to oppose firmly any unilateral 'editing' of scientific appendixes in archæological journals. It further points clearly to the need for planned research and, ultimately, for an Archæological Research Institute embracing all aspects and capable of both research and routine work. Concrete proposals for such a body, it was felt, should be worked out and submitted through the Council to the appropriate quarters as soon as possible.

In one of the concluding remarks the hope was expressed that, as a result of the conference which had thrown this aspect into relief, something might be done to make it easier for archæologists and scientists to understand one another; so that the archæologist could come to know the limitations of scientific techniques, and the scientist in his turn would be able to appreciate archæological requirements. The president, Dr. D. B. Harden, in thanking members of the conference on behalf of the Council, had no doubt that the latter would be glad to do what it could, particularly about 'vetting' material sent for expert examination, in order not to strain the limited resources available. He said that he and other archæologists present had been most encouraged by the support given to the conference; if an Archæological Research Institute still seemed a long way off, it was well worth while working towards it in the best possible way.

As reported in *Nature* of October 9, p. 677, a Scientific Research Committee for Archæology has now been formed by the Council. Further details may be obtained from the Assistant Secretary, Council for British Archæology, 10 Bolton Gardens, London, S.W.5.

L. Biek

PHYSICS OF CLOUDS AND PRECIPITATION

An international symposium was held at the Federal Institute of Technology, Zurich, during October 4–6, under the auspices of the Swiss Federal Commission for the Study of Hail Formation and Prevention, to discuss recent developments in the physics of clouds and precipitation and in the artificial modification of clouds. After the delegates had been welcomed by Prof. R. Sänger, president of the Commission, opening addresses were given by H. Dessens (France) on some theories of cloud nucleation submitted to experimental test, and by B. J. Mason (Great Britain) on the physics of natural precipitation processes.

M. Dessens described studies at the Pûy de Dome of the freezing of water droplets and the growth of ice crystals in the laboratory. The droplets, supported on spiders' threads, were suspended in a cold chamber on the stage of a microscope. Although large drops generally froze at higher temperatures than small ones, he obtained no clear-cut relation between drop size and freezing temperature because the freezing mechanism appeared to be propagated along the thread. However, large drops could be maintained at temperatures above −12° C. for many minutes without freezing.

The seeding of natural supercooled stratus clouds with silver iodide produced ice crystals if the temperature was below −4° C. and was often followed by precipitation and partial dissipation of the cloud. The seeding of similar clouds with 'dry ice' generally resulted in overseeding in the neighbourhood of the source, but precipitation and dissipation of the cloud did not follow. Large-scale seeding with silver iodide was carried out in the Pyrenees during 1951–53, but the effect on the rainfall was inconclusive. Clouds in this region tended to glaciate naturally if their summits were colder than −15° C.

Mr. Mason reviewed the present state of knowledge concerning the physical mechanisms which are responsible for the release of precipitation from both shower- and layer-type clouds. Having traced recent theoretical developments, he analysed the information which has resulted from the exploration of clouds by aircraft and radar to illustrate the conditions under which rain might be produced either by the growth of ice crystals or by the coalescence of water droplets, and to point out how the cloud behaviour might be influenced by geographical and climatic conditions. The conclusion was that in middle latitudes the majority of rain from stratiform clouds is produced by the ice-crystal process and that the coalescence process is normally responsible for only drizzle or light rain. The radar echo from precipitating warm frontal clouds can be satisfactorily interpreted in terms of the growth and multiplication by splintering of ice crystals, their aggregation to form snowflakes, and the aggregation during melting of the latter to form raindrops. In the case of showers, however, it is considerably more difficult to decide which of the possible mechanisms may be dominant.

Calculations on the growth of precipitation elements in model clouds indicate the conditions under which showers may be released by coalescence (initiated, for example, by large hygroscopic nuclei), by the growth of ice particles, by the shedding of water drops from wet hailstones and by a process of raindrop multiplication due to disruption of large drops (raindrop chain reaction). In middle latitudes during the summer, and particularly over the sea, the coalescence process may forestall the ice particles in releasing precipitation even though the tops of the clouds may afterwards show glaciation. This may account for the fact that hail falls from only a small fraction of these clouds. The coalescence mechanism will be even more favoured in the deep, warm clouds of tropical regions where the conditions may often be suitable for the rapid multiplication of raindrops by a chain reaction.

In a session devoted to atmospheric aerosols, E. M. Fournier d'Albe described how the concentration and size distribution of large hygroscopic nuclei were measured at five ground-level stations in Pakistan. Near the coast the concentrations of particles with mass greater than 10^{-9} gm. were of order 100/m.^{3} but fell off rapidly inland. Although these particles were depleted during heavy rain, there was some evidence that hygroscopic nuclei were left behind when raindrops evaporated before reaching the ground. Dr. Fournier d'Albe thought that the main source of these particles was the sea and that they were responsible for releasing showers by initiating a chain reaction in the warm cumulus clouds of Pakistan.

O. Vittori (Italy) described microchemical tests for identifying microscopic and submicroscopic particles. The particles when caught on gelatine containing dissolved salts produce coloured rings of precipitate; particles of mass down to 10^{-15} gm. may be detected. This technique has been used to identify sulphate and chloride particles in the atmosphere and also various artificial aerosols such as silver nitrate. Some preliminary experiments for the physico-chemical detection of minute silver iodide particles were also described. It is not yet possible to determine accurately the masses of the particles by these methods.

Prof. C. G. Rossby (Stockholm) showed some results which had emerged from the chemical analysis of rainwater in Sweden, in particular the geographical distribution of various elements as measured over a two-year period. The total deposits of sodium and chlorine fell off very rapidly from west to east, much more rapidly than does the rainfall. The ratio chlorine/sodium by weight in the deposit showed a definite geographical pattern with values of 1·2 near the coast falling off to 0·6 well inland; these values have to be compared with a ratio of 1·8 for sea water. The distribution of calcium was fairly uniform over the country, but the ratios of calcium/sodium and potassium/sodium were generally much higher than those found in sea water.

In studying the supercooling of water drops supported on a metal plate, W. Rau (Germany) has found some evidence for the spectrum of freezing nuclei having maxima at −4° C., −11° C. and −19° C. Aqueous solutions show the same general spectrum of freezing nuclei but displaced to lower temperatures. Dr. Rau believes that precipitation from natural clouds tends to occur at rather well-defined temperatures and that this can be explained in terms of his spectra of freezing nuclei. He has measured the ice nucleus contents of air samples of different origin and has found polar air masses to contain many very efficient ice nuclei which are absent from subtropical air; he concludes that these nuclei were of maritime origin. He believes that the freezing of supercooled cloud droplets at −40° C. is brought about by freezing nuclei and that spontaneous nucleation occurs only at temperatures below −70° C. when cubic ice crystals are formed. He said that he had repeated his earlier experiments in view of criticisms that his apparatus may have been contaminated by alcohol, and he now reported that he can confirm his earlier results.

G. Soulage (France), having grown ice crystals in the atmosphere and allowed them to evaporate, found that their residues could act as centres for the formation of ice crystals at temperatures between −12° and −15° C. The particles had no particular crystalline shape, were partly insoluble and partly hygroscopic and acted as ice nuclei only after liquid water had condensed on them.

In a discussion on cloud physics, H. Byers (Chicago) described recent studies of cumulus clouds in Puerto Rico and in the middle of the United States with radar-equipped aircraft. The tropical clouds forming over the sea were relatively slow-growing and gave radar echoes when little more than 6,000 ft. deep, so that they were entirely below the 0° C. isotherm. Those forming over the island, however, showed much more rapid development, but did not precipitate until they attained considerably greater depths. The cloud droplets of tropical cumulus had a bimodal size distribution with maxima diameters of 10–15 μ and 30–50 μ, the latter no doubt being responsible for starting the coalescence process. In order to illustrate further the geographical differences of cloud populations, Prof. Byers also reviewed radar studies made of summer cumulus in New Mexico, which often reaches great heights without precipitating, and of thunderstorms in Ohio where the initial radar echo, in the majority of cases, is entirely below the 0° C. level, suggesting that the precipitation is initiated by coalescence.

F. H. Ludlam (London) described the observations made in central Sweden this summer as a part of a field-programme organized jointly by the Imperial College of Science and Technology, London, and the Institute of Meteorology, University of Stockholm. The behaviour of cumulus was studied with the aid of small aircraft, double theodolites, time-lapse photography and radar. Particular attention was paid to the growth-rates of the clouds, their development during the day and the onset of precipitation. Careful studies of the glaciation of cloud summits indicated that this sometimes occurred at temperatures as high as −4° C. Showers sometimes fell from clouds little more than 1 km. deep.

The instrumentation of the aircraft of the British Meteorological Research Flight was described by R. J. Murgatroyd. A very rapid hot-wire thermometer was used to determine the thermal structure of the air below the bases of cumulus, while the airflow around the sides of the cloud was studied by following the relative motions of packets of 'window' with radar. Vertical currents inside clouds were measured with an integrating accelerometer and the liquid-water content with both a hot-wire instrument and a refrigerated icing disk. With the latter instrument, full adiabatic values of the water content were found in cold clouds. Measurements of the drop-size distribution in clouds by means of slides coated with either magnesium oxide or oil showed drops of radius 20–25 μ near the bases of stratocumulus clouds which were occasionally observed to produce rain if more than 4,000 ft. thick. Mr. Murgatroyd has evidence that in southern England summer showers are often released by coalescence and that even small cumulus often contains many drops of diameter 50 μ. Ice crystals appeared in detectable numbers only at temperatures below −12° C.

V. J. Schaefer (United States) outlined the cloud physics programme of the Munitalp Foundation, in particular the attempts to make a survey of cloud development at various sites in the United States with the help of voluntary observers using ciné cameras. He showed a number of colour films of clouds taken by members of the United States Forestry Service and of cloud systems which were associated with jet streams. M. Bossolasco (Milan) described some observations of precipitating clouds made at a mountain observatory and attempted to correlate the onset of precipitation with the temperature at screen level. G. Fea (Rome) reported on methods which were used to measure liquid-water content of clouds on Monte Cimone. G. Yamamoto (Japan), in his studies of the initial growth stage of ice crystal on nuclei of silver chloride and silver nitrate, has found crystals which are square rather than hexagonal prisms.

The main contribution on cloud seeding came from E. Bollay, who has conducted large-scale commercial trials in the United States, mainly with the object of increasing the snowpack in the lee of the Sierras. Silver iodide smoke was released on all occasions when clouds in the target area surpassed the −5° C. evel. The results were evaluated using a regression method in which past rainfall data were used to obtain a regression curve between the rainfall of the target and a control area, this being used to predict the rainfall to be expected naturally in the target area during the seeding period. Mr. Bollay estimates that in four successive years of operations in the Central Sierras they increased the snowpack by 27, 21, 7 and 22 per cent respectively. An independent assessment of three other operations by the Statistical Laboratory of the University of California suggests that in one case the rainfall showed a decrease, in another there was a considerable increase, the third being inconclusive.

In recognizing that there are certain factors which militate against commercial undertakings being able to carry out seeding experiments in the most scientifically acceptable form, Mr. Mason said that it is important for those interested in the purely scientific aspects of the problem to give considerable thought to the design and execution of a large-scale experiment. The results can be evaluated only on a statistical basis, and he indicated how an experiment might be designed using control and target areas, the decision to seed being made on the basis of a random choice. Such an experiment would probably take at least five years if rainfall increases of order 15 per cent were to be detected with reasonable confidence. Dr. Fournier d'Albe showed a film to illustrate how warm cumulus clouds were inoculated with salt particles dispersed from the ground in two areas in Pakistan. Particles of mass greater than 10^{-9} gm. were dispersed at a rate of 10 gm./sec., about half being carried aloft by the air. Although there was some preliminary indication that the rainfall was higher in the target regions than outside, a complete analysis of the results has not yet been made.

After three days of lectures and discussions, visits were arranged to the Institute for Snow and Avalanche Research on the Weissfluhjoch, Davos, and to the observatory of the Meteorologische Zentralanstalt at Locarno. These gave delegates an opportunity of seeing something of this beautiful country in which they were received with such friendliness and hospitality.

B. J. Mason

MARIE CURIE CELEBRATIONS IN WARSAW

The twentieth anniversary of the death of Marie Sklodowska-Curie was celebrated at a special session of the Polish Academy of Sciences at Warsaw during October 6–8. This session was attended by Mrs. Irene Joliot-Curie, Madame Curie's daughter, and by specialists on various aspects of radioactivity from China, Czechoslovakia, France, Great Britain, Hungary, Norway and the U.S.S.R., as well as by a large number of Polish scientists who had gathered there from all parts of the country. Madame Curie's elder sister was a guest of honour, and in spite of her great age she was present at all the numerous functions of the session.

The first two days of the session were partly devoted to official speeches and surveys of the various physical and medical applications of radioactivity. Noteworthy was the speech by Mrs. Irene Joliot-Curie, in which she analysed her mother's work in a most vivid and personal way. Moreover, the participants attended the inauguration of a museum devoted to Madame Curie and installed in the newly rebuilt house where she was born in the so-called "New City" (which is actually an eighteenth-century extension of the Old Town). In this museum an extensive collection of documents and apparatus pertaining to Madame Curie is displayed in a most effective manner. The successive rooms are devoted to Madame Curie's childhood and family circle, her years of study in Paris, her great work in collaboration with her husband, her activities in promoting the medical use of radioactivity and her leadership of the Institut du Radium at Paris. The last rooms evoke the development of nuclear physics, which had its origin in the discovery of radioactivity, and lead the visitor to an impressive display of photographs illustrating on one hand the devastating use of nuclear energy in destroying cities and their inhabitants, and on the other the applications of nuclear energy for medical and industrial purposes (including a photograph of the first nuclear power station recently put into operation in the Soviet Union).

The last day of the session was entirely devoted to a more technical discussion of physical problems, and was held in the main lecture room of the Physical Institute. Among others, Prof. J. Rayski, of the University of Toruń (who is well known to nuclear physicists in Great Britain), presented a new interpretation of the various kinds of particles recently discovered in cosmic radiation. The Academy of Sciences and the State authorities also organized official receptions of the participants, who enjoyed, during the whole duration of their stay, the most cordial hospitality.

For the occasion the Academy of Sciences, which displays considerable activity in publishing scientific periodicals and excellent journals aiming at the popularizing of science, had issued a series of valuable books. These comprise Polish translations of Madame Curie's "Traité de Radioactivité", of Mrs. Irène Joliot-Curie's shorter text-book on nuclear physics, and also of Madame Curie's delightful short biography of her husband which originally appeared in French in 1924. Another book contains a collection of articles by various Polish scientists surveying Madame Curie's work and its implications, as well as a reprint of two articles written in Polish by Madame Curie. Last, but not least, a magnificent volume has been prepared containing a reprint in the original language (mostly French or Polish) of the complete works of Madame Curie. It is interesting to see to what extent Madame Curie was anxious to write popular articles or more technical surveys on the development of radioactivity in her native language. A bronze medal bearing the figure of Madame Curie was struck to commemorate the celebration.

The present writer had the opportunity of visiting in detail the Warsaw Physical Institute and of discussing questions of common interest with Polish physicists there. He was much impressed by the activity with which the newly reorganized Institute was teeming, and with the results already achieved in a surprisingly short time in trying circumstances. The Experimental Department of the Institute, under the direction of Prof. L. Sosnowski, pursues no less than four lines of investigation. Prof. Sosnowski himself is interested in problems of semiconductors; there is a section on nuclear physics (Prof. A. Soltan), a section on the study of cosmic rays by the emulsion technique (Prof. M. Danysz), and a section on optical and X-ray spectroscopy, which was set up by the late Prof. S. Pieńkowski, the creator of the Institute after the First World War. The Theoretical Physics Department occupies a new wing which was recently built in the space of a few months and which offers a group of very keen and active young theoreticians ideal conditions of work under the leadership of the two well-known theoretical physicists, Prof. L. Infeld and Prof. W. Rubinowicz. There are flourishing centres of research in physics at the other universities, which the writer had, however, no time to visit. The general impression from his brief contact with Polish physicists is that of a remarkably vigorous activity and growth, worthily upholding the brilliant traditions of Polish science.

L. Rosenfeld

SOCIAL IMPLICATIONS OF THE GENETICS OF MAN

In his presidential address to the Pacific Division of the American Association for the Advancement of Science, Prof. A. H. Sturtevant, of the California Institute of Technology, dealt with two matters. First, he emphasized the peculiar difficulties in the way of building up a sound body of knowledge on the formal genetics of man. These account for our gross ignorance of the part played by heredity, for example, in mental differences. Secondly, he considered the problems set by the genetical consequences of atom and hydrogen bombs.

Stressing that, for their effects on heredity, there is no lower level at which high-energy radiations are harmless, Dr. Sturtevant deprecated the statement by the Chairman of the Atomic Energy Commission that "... after every test ... there is a small increase in natural background radiation in some localities within the U.S.A. ... far below the levels which could be harmful in any way to human beings ...".

Dr. Sturtevant made the point that the risk is one to which the whole of mankind is already being subjected, and, if mankind survives for many generations, the bombs already exploded will ultimately and inevitably result in an increase in the harvest of defective individuals.

Few biologists will disagree with Dr. Sturtevant's criticism of the attitude exemplified above. The genetical consequences of a world atomic war would, clearly, be trivial compared with the immediate results. If mankind cannot avoid such a war there is not much point in speculating on the genetical consequences. But if it should be avoided, then a permanent increase, no matter how small, in radioactivity, be it due to industrial waste products or to the tests mentioned by Dr. Sturtevant, might become of tremendous importance. With present knowledge we are not even in a position to make a few intelligent guesses. It is to be regretted that Dr. Sturtevant, besides deprecating the light-hearted attitude towards biological problems mentioned above, did not also consider the consequences of the development of atomic energy for peaceful purposes. It seems to the reviewer that we are taking incalculable risks by building the factories without concentrating as much energy and money on the study of the long-term biological consequences of the atomic age.

G. Pontecorvo

UNITED NATIONS TECHNICAL ASSISTANCE BOARD

REPORT FOR 1953

The sixth report on the United Nations Expanded Programme of Technical Assistance for Economic Development*, submitted by the Technical Assistance Board to the Technical Assistance Committee of the Economic and Social Council, describes the progress of the programme during 1953, the third financial period. It also includes information on the approved programme for 1954 and some details on that proposed for 1955. Almost 200 out of the 267 pages of the report are occupied by the statements of the participating organizations and an analytical summary of the programmes for 1953–55 taken country by country. The general features of the Expanded Programme are discussed in an introduction which is illustrated by a series of diagrams and charts; and, in view of what has already been recently published in *Nature* (173, 50 and 174, 1; 1954), it is unnecessary here to refer to more than a few points.

---

* United Nations Technical Assistance Committee. Sixth Report of the Technical Assistance Board. Economic and Social Council—Eighteenth Session—Supplement No. 4. Pp. vii+267. (New York: United Nations; London: H.M.S.O., 1954.) 2.50 dollars; 17s. 6d.; 10 Swiss francs.

In the four years since the Programme began, the less-developed countries have re-examined their economic and social problems and have invited many thousands of experts from many lands to work with and for them. The technical skill and experience of many countries have been drawn upon to accelerate progress where it has lagged, and the report claims that in some measure the energies and initiative, the hopes and capacity for self-help of many peoples have been quickened. Nevertheless, the volume of technical assistance fell slightly, from 22,968,129 dollars in 1952 to 22,810,000 dollars, partly in consequence of a thorough review of the Programme, when pledges for 1953, totalling 22·4 million dollars, fell far below the cost of the technical assistance requested. The number of countries and territories receiving experts, however, increased from sixty-two to sixty-five, although fellowships were awarded to nationals of only eighty-two countries, compared with ninety-two in 1952, and sixty-seven, as compared with seventy-six, countries or territories acted as hosts to Fellows.

Attempting to distinguish features of the Programme on the basis of five years of operation, the report points out that only a small proportion of the funds is required to meet urgent priority requests: most technical assistance is designed to assist the less-developed countries in themselves solving chronic and age-long problems and represents only a fraction of sustained national effort required for appreciable and enduring results. The approved programme for 1954, for example, includes some eight hundred projects in each of which the average number of experts is about two throughout the year, and a hundred and fifteen projects which include only one fellowship each and no experts. Secondly, relatively little equipment is provided with the expert assistance: in 1953 only 10 per cent of obligations was for equipment and only about 6 per cent is planned for 1954. Thirdly, the Expanded Programme is not related directly to any source of capital supply.

Experience seems to show that a large proportion of the Programme in widely different fields must be devoted to training national personnel in the less-developed countries. Often these training facilities are linked with, or followed by, the award of fellowships to candidates recommended by the government concerned to enable them to follow a specified course at teaching institutions abroad. In many countries international experts have assisted governments in developing the institutional framework required for experimental work, pilot projects and development. It is also emphasized that the degree of under-development and the requirements of various countries differ widely, and in most fields specific instruction and demonstration as to how to do things are taking the place of general advice as to what needs to be done.

During the year attempts were made for the first time to work out comprehensive technical assistance programmes at the country-level, and special attention to the possibilities of economy in the Board's field establishments led to a 24·5 per cent reduction in the estimated costs of these establishments for 1954. The holding of the Pledging Conference before the beginning of the Programme year also eased financial management in 1953, and the approval by the Technical Assistance Committee and the Economic and Social Council of proposals for the establishment of a reserve which might be utilized as a working capital and reserve fund should enable the Board to make advances to tide over time-lags between pledges and payment and to satisfy special currency requirements. Financial ceilings are now being imposed on obligations in order to regulate the rate of expenditure in relation to the rate of estimated collection. The Board is also re-examining the criteria and techniques to be used in judging the results of individual projects and the effectiveness of country programmes as a whole. In spite, however, of the improvement in financial management, the determined attack on administrative costs, the stronger co-operation between governments, agencies and the Board's representatives at the country-level and the improved co-ordination with other technical assistance programmes, much remains to be done to improve the operation of the Programme, to make more effective use of limited resources and to come to terms with the dimensions of the task for which the Expanded Programme was created. Once again it is clear that educational and economic advance should go side by side. Neither should dominate the other. This report should assist in formulating a clear conception of the principles involved in technical aid and what they require; and to overcome the difficulties encountered in obtaining a sufficient supply of experts and retaining their services, it may well prove necessary to form an international cadre with continuous and guaranteed agreed terms of service operating for something in the nature of a World Development Authority.

FISH CULTURE IN INDONESIA

THERE has recently been published by the Food and Agriculture Organization (F.A.O.) a highly important report* on fish culture in Indonesia. This report comprises a selection of the papers delivered and discussed at a seminar on brackish- and fresh-water fish culture, held at Djakarta during April 11–May 23, 1951, under the ægis of the Indo-Pacific Fisheries Council.

It is now generally recognized that the fish resources of the sea, vast though they be, are not limitless, nor are they uniformly distributed throughout the seas and oceans of the world. In many highly populated regions of the earth, especially within the tropics, the marine fisheries are as yet poorly developed and their yields make inadequate contributions to the needs of the inhabitants. In consequence, great effort is being made in many such regions—much of it under the inspiration and guidance of the Food and Agriculture Organization—to increase the yield of sea foods.

---

* Fish Culture in Indonesia. G. L. Kesteven, General Editor. Indo-Pacific Fisheries Council (F.A.O.) Special Publication No. 2. I.P.F.C. Secretariat, F.A.O. (Regional Office for Asia and the Far East, Bangkok, 1953.) n.p.

This can be done only by streamlining and improving fishing methods and intensifying fishing effort. It is already clear, however, that in many places the ultimate yields from the sea's natural resources can never fully meet the unsatisfied demands for animal proteins; and no means have yet been found of adding appreciably to the sea's productivity by culture methods. Fish farming is not feasible in the sea; but in brackish lagoons and fresh inland waters it is both possible and profitable and has long been practised in various parts of the world.

Great effort to improve and extend the practice of fish culture in fresh and brackish waters is therefore now being made, especially in the Indo-Pacific region. This volume on fish culture in Indonesia is thus a most valuable document. It opens with a general description of the inland fisheries of Indonesia followed by reports on: (1) the anatomy and physiology of the milkfish or bandeng, *Chanos chanos*; (2) the capture and transportation of its fry for stocking purposes; (3) the breeding of carp, *Cyprinus carpio*; (4) the plankton populations of brackish-water ponds; (5) the occurrences of *Anopheles* larvæ in rice fields during combined cultivation of rice and fish. There are also brief notes on many other allied problems.

Practical fish culturists and all others interested in improving and extending the science and art of fish culture will be grateful to the Food and Agriculture Organization for providing in this publication such a rich fund of useful information.

The Organization has also published a second (revised) edition of its valuable List of Scientific and other Periodicals published in the Indo-Pacific Area*.

PARTICIPATION OF COENZYME A IN THE OXIDATION OF FAT*

By Prof. F. LYNEN

Biochemical Department, University Chemical Laboratory, Munich

RESEARCH in recent years has greatly increased our understanding of the pathways involved in fat metabolism and has confirmed the classical β-oxidation theory of Knoop[1] as the chief process by which fatty acids are oxidized. Fatty acid chains undergoing this process are cleaved into C_2-fragments, until recently known as 'active acetate', as their true nature was a mystery. The discovery of coenzyme A by Lipmann[2] was followed by that of the 'energy-rich' acylmercaptans or thioesters[3]. This led to the identification, three years ago, of 'active acetate' as the thioester formed from coenzyme A and acetic acid (acetyl-coenzyme A)[4]. Knowing this, it was possible to formulate a provisional scheme for the oxidation and synthesis of fatty acids[4-6]. The essentials of this scheme were soon confirmed, owing to the rapidity with which the enzyme systems involved were isolated and studied by several laboratories[7-10], including my own in Munich[11].

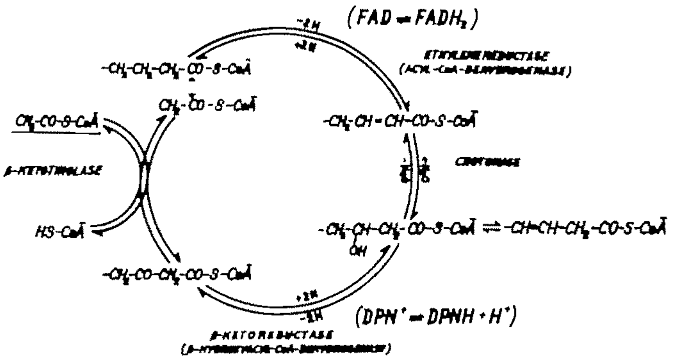

Fig. 1. Fatty acid cycle

This scheme (Fig. 1) represents a 'fatty acid cycle'. The synthesis of fatty acids is achieved by a repetition of four consecutive steps, catalysed by four new enzymes, which hand to each other substrates of different chain-length. (Recent experiments show that there exist two ketothiolases[7] and two ethylene reductases[8], each specific to substrates with certain chain-lengths.) I have named these enzymes according to the direction of their equilibria under physiological conditions. The four steps are as follows: (1) one molecule of acetyl-coenzyme A condenses with another, giving acetoacetyl-coenzyme A; (2) acetoacetyl-coenzyme A is reduced to β-hydroxybutyryl-coenzyme A in the presence of reduced diphosphopyridine nucleotide; (3) β-hydroxybutyryl-coenzyme A undergoes dehydration to crotonyl-coenzyme A; (4) crotonyl-coenzyme A is reduced to butyryl-coenzyme A in the presence of reduced flavine.

In these four steps the carbon chain of the original acetyl-coenzyme A is extended by two carbon atoms. An additional acetyl-coenzyme A and four additional hydrogen atoms are required. The butyryl-coenzyme A so formed can re-enter the cycle through condensation with another molecule of acetyl-coenzyme A to give ketocaproyl-coenzyme A, afterwards undergoing reduction to caproyl-coenzyme A. The repetition of the cycle eight times in a spiralwise manner will produce stearyl-coenzyme A (C_{18}). Fatty acid coenzyme A derivatives formed in the 'spiral' can transfer their acyl groups to α-glycerophosphate, forming diacyl phosphatidic acids[12], possible precursors of the phosphatides and true fats. The transferring enzyme concerned is highly specific for fatty acid chains of 16, 17 or 18 carbon atoms, which may account for

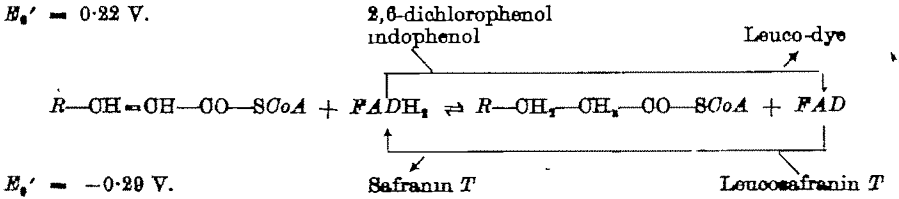
* Summary of a lecture given on March 8 at University College, London. The experimental work reported was aided by grants from the Deutsche Forschungsgemeinschaft, Bad Godesberg, and the Rockefeller Foundation, New York.

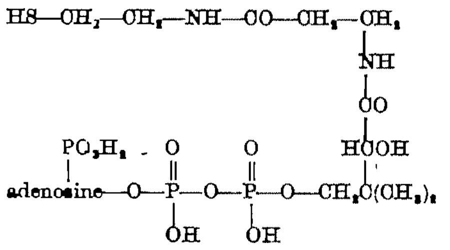
the preponderance of palmityl and stearyl glycerides in Nature. By reversing the 'spiral' the complete degradation of a fatty acid chain into C_2-fragments can occur, provided that the fatty acid is first activated by combination with coenzyme A.



$$R\text{—CH=CH—CO—}SCoA + FADH_2 \rightleftharpoons R\text{—CH}_2\text{—CH}_2\text{—CO—}SCoA + FAD$$

(*FAD* = flavine adenine dinucleotide, *FADH*$_2$ = reduced *FAD*)

The study of these four new enzymes in our laboratory in Munich has been based on the application of the elegant optical methods of Warburg[12], and on the wide use of model derivatives of coenzyme A—the derivatives of N-acetyl cysteamine, an analogue of coenzyme A.



Coenzyme A

HS—CH_2—CH_2—NH—CO—CH_2—H

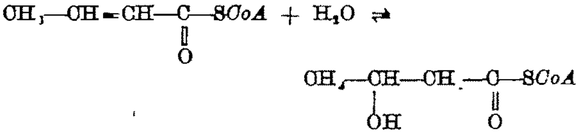
N-Acetyl cysteamine

These model compounds were first prepared by us with the object of obtaining information about the chemical properties of the predicted intermediaries of the fatty acid cycle (Table 1). They also proved to be of great value in the study of enzyme reactions. Not only are they inexpensive and readily available (unlike coenzyme A and its derivatives), but they can also be prepared in the laboratory as analytically pure compounds. Some of them possess, in common with the coenzyme A derivatives, strong absorption bands in the ultra-violet. The S-crotonyl and S-acetoacetyl derivatives possess absorption bands at 263 mμ and 303 mμ ($pH > 8$, enolic form) respectively, and the thioesters of the saturated fatty acids and the β-hydroxyacids have a band at 233 mμ [14]. The model compounds must be used at higher concentrations than the corresponding coenzyme A derivatives, as the enzymes concerned have a lower affinity for them. The models possess the correct configuration of atoms next to the active group but lack the anchor, perhaps provided by the phosphate groups of coenzyme A, for their firm attachment to the enzyme. In this respect the enzymes of the fatty acid cycle may resemble the triose phosphate dehydrogenase[13,15].

Ethylene reductase is a flavoprotein enzyme with flavadenine dinucleotide as prosthetic group, an observation made independently in Munich[16] and in Madison[17,17a]. It catalyses the oxido-reduction between saturated fatty acid derivatives of coenzyme A and flavine, and can also react with the model compounds. This reaction may be followed spectrophotometrically by observing either the bleaching of 2,6-dichlorophenol indophenol by the saturated fatty acid derivatives, or the regeneration of colour from leucosafranin *T* by the S-crotonyl derivatives.

The enzyme was purified four hundred times from sheep liver extract, using the second reaction for the assay system[16]. The enzyme has the same affinity for model as for natural compounds, but, in order to achieve the same velocity at identical substrate concentrations, three times more enzyme is needed with the model compound than is needed with the natural one. This suggests that the transfer of hydrogen from the natural substrate to flavine is three times more rapid than the transfer from the model compound. The rate of oxidation of the model fatty acid derivatives increases with chain-length. We have evidence that our purified ethylene reductase is different from the 'acyl-coenzyme A dehydrogenase', isolated in Madison[17].

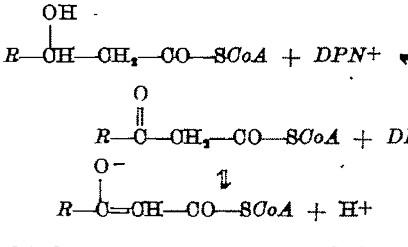
Crotonase catalyses the reversible hydration of the thioesters of the unsaturated acids to the corresponding β-hydroxyacids[18,19].



$$CH_3\text{—CH=CH—}\underset{\underset{\displaystyle O}{\|}}{C}\text{—}SCoA + H_2O \rightleftharpoons CH_3\text{—}\underset{\underset{\displaystyle OH}{|}}{CH}\text{—CH}_2\text{—}\underset{\underset{\displaystyle O}{\|}}{C}\text{—}SCoA$$

This reaction may be followed by measuring changes in the absorption band of S-crotonyl derivatives at 263 mμ[7]. The extinction coefficient of this band is sufficiently high to prevent significant interference by the adenine band of coenzyme A at 260 mμ. Crotonase can remove water from β-hydroxybutyryl-coenzyme A to give vinyl-acetyl-coenzyme A[18,19], an unsaturated fatty acid with the double bond between carbons 3 and 4. The incorporation of such a fatty acid into a chain undergoing synthesis in the 'spiral' could explain the distribution of double bonds, in a number of naturally occurring unsaturated fatty acids (for example, linolenic, $C_{9:10}$, $C_{12:13}$, arachidonic, $C_{5:6}$, $C_{11:12}$).

β-*Ketoreductase* catalyses the reduction of the S-acetoacetyl derivatives of coenzyme A and N-acetyl cysteamine to the corresponding β-hydroxyacid derivatives, using reduced diphosphopyridine nucleotide (*DPN*H) as hydrogen donor[20,20a].



$$R\text{—}\overset{\overset{\displaystyle OH}{|}}{CH}\text{—CH}_2\text{—CO—}SCoA + DPN^+ \rightleftharpoons R\text{—}\overset{\overset{\displaystyle O}{\|}}{C}\text{—CH}_2\text{—CO—}SCoA + DPNH + H^+ \rightleftharpoons R\text{—}\overset{\overset{\displaystyle O^-}{|}}{C}\text{=CH—CO—}SCoA + H^+$$

Of the two enantiomorphs of the β-hydroxyacid, only the D-compound takes part in the reaction[19]. This may be followed by using S-acetoacetyl-N-acetyl cysteamine as the substrate, and measuring the disappearance of reduced diphosphopyridine nucleotide.

Considerable purification of the enzyme from sheep liver was obtained, using this assay system[18]. The affinity of the enzyme for its natural substrate is one hundred times greater than its affinity for the model compound. At physiological pH the equilibrium of the reaction lies towards oxidized diphosphopyridine nucleotide and β-hydroxyacyl-coenzyme A, but shifts towards the S-acetoacetyl compound with rising pH. Above pH 8·5 the acetoacetylmercaptan dissociates to give the enolate ion. The latter effect can be used in the preparation of S-acetoacetyl or higher β-ketoacyl derivatives of coenzyme A. This was first done in our laboratory in Munich[20] and later elaborated by Bemert in Madison[21]. Various tissues have been examined for the presence of the enzyme. Of all the organs tested, the brain was found to contain very little (Fig. 2), which agrees with the well-known fact that this organ can metabolize carbohydrate but not fat.

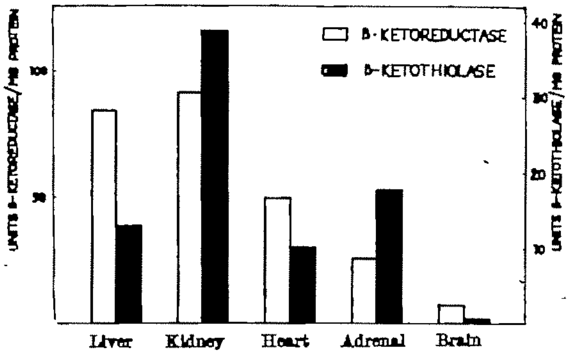


Fig. 2. Occurrence of β-keto reductase and β-keto thiolase in various sheep tissue-extracts

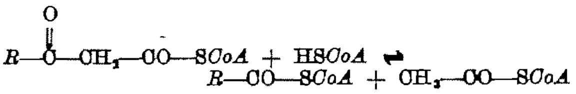
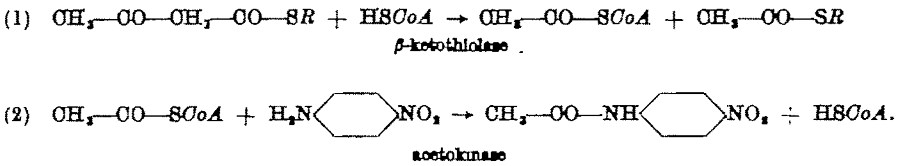
β-*Ketothiolase* catalyses the reversible cleavage of acetoacetyl-coenzyme A into two molecules of acetyl-coenzyme A[7,21]. The equilibrium of the reaction under physiological conditions lies towards the thiolytic cleavage, one thousand molecules of acetyl-coenzyme A being in equilibrium with about five molecules each of acetoacetyl- and free coenzyme A.



$$R-\overset{\substack{O\\ \|}}{C}-CH_2-CO-SCoA + HSCoA \rightleftharpoons R-CO-SCoA + CH_3-CO-SCoA$$

The reaction may be followed by observing changes in the absorption band of acetoacetyl-coenzyme A at 303 mμ[14]. The model compound, S-acetoacetyl-N-acetyl cysteamine, can replace the natural substrate, but at such high concentrations that the reaction cannot be followed at 303 mμ. This difficulty can be overcome by coupling the enzyme with the acetokinase for aromatic amines from pigeon liver. The acetyl-coenzyme A formed by the thiolytic cleavage acetylates p-nitroaniline, giving an almost colourless compound[22], and the overall reaction can be followed optically[23].



$$(1)\quad CH_3-CO-CH_2-CO-SR + HSCoA \underset{\beta\text{-ketothiolase}}{\rightarrow} CH_3-CO-SCoA + CH_3-CO-SR$$

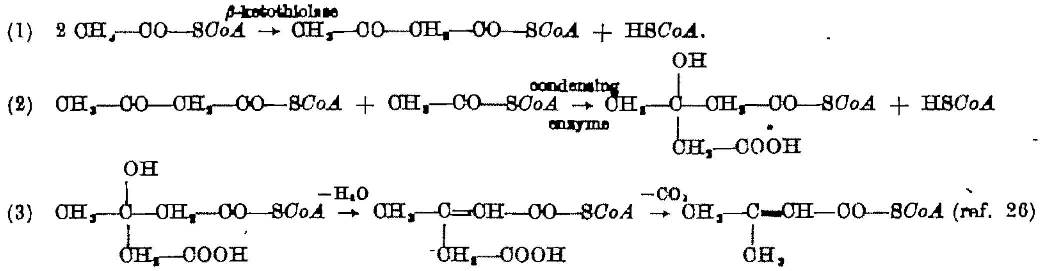
Acetoacetyl-coenzyme A and acetoacetyl-glutathione will also react in this system, showing the wide range of the β-ketothiolase, the only enzyme so far known which will react with the S-acyl derivatives of glutathione.

We have come to the conclusion that the enzyme participates in the reaction, in the following stoichiometric manner, by means of a thio group, which is essential to its activity[14].

$$(1)\quad \text{Enzyme } SH + CoAS-CO-CH_2-CO-CH_3 \rightleftharpoons \text{enzyme } S-CO-CH_3 + CoAS-CO-CH_3.$$

$$(2)\quad \text{Enzyme } S-CO-CH_3 + CoASH \rightleftharpoons \text{enzyme } SH + CoAS-CO-CH_3.$$

The distribution of the enzyme in certain tissues is shown in Fig. 2. The great accumulation of the enzyme in the suprarenal gland suggests that it might participate in the synthesis of steroids from acetyl groups, via squalene[24]. We suggested more than two years ago that a 'building block' suitable for such biosyntheses, and containing five carbon atoms in an isoprene structure, could be produced in a fashion analogous to the *in vivo* synthesis and transformation of citrate[25].



$$(1)\quad 2\,CH_3-CO-SCoA \xrightarrow{\beta\text{-ketothiolase}} CH_3-CO-CH_2-CO-SCoA + HSCoA.$$

$$(2)\quad CH_3-CO-CH_2-CO-SCoA + CH_3-CO-SCoA \xrightarrow[\text{enzyme}]{\text{condensing}} CH_3-\underset{\substack{|\\ CH_2-COOH}}{\overset{\substack{OH\\ |}}{C}}-CH_2-CO-SCoA + HSCoA$$

$$(3)\quad CH_3-\underset{\substack{|\\ CH_2-COOH}}{\overset{\substack{OH\\ |}}{C}}-CH_2-CO-SCoA \xrightarrow{-H_2O} CH_3-\underset{\substack{|\\ CH_2-COOH}}{C}=CH-CO-SCoA \xrightarrow{-CO_2} CH_3-\underset{\substack{|\\ CH_3}}{C}=CH-CO-SCoA \text{ (ref. 26)}$$

Activation of fatty acids. In the fatty acid cycle fatty acids are not metabolized in the free form, and prior to oxidation must undergo activation by combination with the thio group of coenzyme A[7,26a,26]. Three enzymes are known which catalyse this reaction. One, which has received the most intensive study, activates acetate and propionate[7,26a,26]; another activates fatty acids, unsaturated fatty acids and β-hydroxy-acids of chain-length C_4–C_{11} [27]; and a third activates higher fatty acids up to C_{22} [28]. The activation needs energy from adenosine triphosphate[29], which was shown by Lipmann and his co-workers to split into adenosine monophosphate and pyrophosphate during the activation of acetate[30]. The recent collaboration of our team with Lipmann's elucidated the mechanism of acetate activation[31]. This seems to require the stoichiometric participation of a group (X) on the enzyme in a three-step reaction:

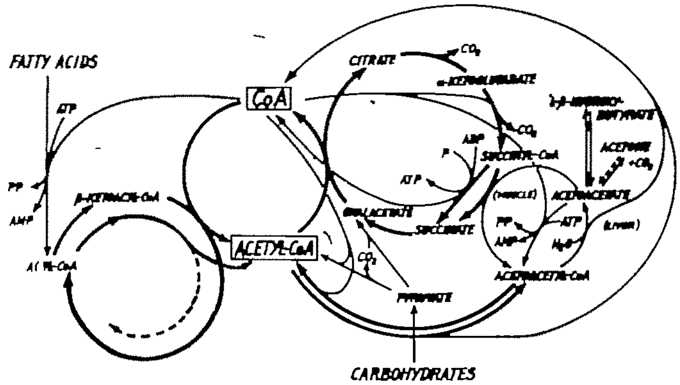


Fig. 3. Interaction of the fatty acid cycle and the citric acid cycle

(1) $\text{Enzyme } X + Ad{-}P{\sim}PP \rightleftharpoons \text{enzyme } X{\sim}P{-}Ad + PP.$

(2) $\text{Enzyme } X{\sim}P{-}Ad + HSCoA \rightleftharpoons \text{enzyme } X{\sim}SCoA + Ad{-}P.$

(3) $\text{Enzyme } X{\sim}SCoA + CH_3COOH \rightleftharpoons \text{enzyme } X + CH_3CO{\sim}SCoA.$

(Ad = adenosine, $Ad{-}P$ = adenosine monophosphate, PP = pyrophosphate).

It has been known for many years that the metabolism of fat is closely integrated with that of carbohydrate, but only now is it possible to have a clear picture of this integration at the enzymatic level (Fig. 3). For the synthesis of fat the fatty acid cycle is dependent upon the supply of acetyl-coenzyme A and reduced diphosphopyridine nucleotide, derived from the breakdown of carbohydrate. A high concentration of these substrates must be maintained, and the concentration of free coenzyme A kept low, if the equilibria of the β-ketothiolase and the β-ketoreductase are to be shifted in the direction of synthesis. In the living organism the supply of these two substrates is crucial in deciding if fat is to be synthesized or oxidized. In diabetes, where the metabolism of carbohydrate is depressed, the stationary concentration of reduced diphosphopyridine nucleotide in the liver is lowered[23] and the synthesis of fatty acids restricted.

The acetyl-coenzyme A derived from the oxidation of fatty acids passes into the citric acid cycle by condensation with oxaloacetate, to be oxidized to carbon dioxide and water. The level of fatty acid oxidation is therefore determined by the rate at which oxaloacetate becomes available. If this rate falls off, through the depression of carbohydrate metabolism, as in diabetes, then acetyl-coenzyme A cannot be metabolized completely. Acetoacetyl-coenzyme A accumulates and gives rise to the 'ketone bodies' of the blood by being hydrolysed by a deacylase, found only in liver, to give free acetoacetate. Acetoacetate may be reduced or decarboxylated to β-hydroxybutyrate or acetone. In normal animals acetoacetate can be used to provide energy[33], for once activated with coenzyme A it will give rise to acetyl-coenzyme A, which enters the citric acid cycle. Two such activating mechanisms are known. Stern[34] and Green[35] discovered independently an enzyme which exchanges acetoacetate with the succinate of succinyl-coenzyme A (arising from the citric acid cycle) to give acetoacetyl-coenzyme A and free succinate. There is also an enzyme, found mainly in kidney[36], which catalyses the direct activation of acetoacetate with coenzyme A and adenosine triphosphate. The level of the blood acetone bodies will be controlled by the inter-relationships of such systems producing and utilizing acetoacetate.

The smooth integration of fat and carbohydrate metabolism depends upon a steady turnover of coenzyme A. Free coenzyme A is acylated in the activating and thiolysing steps, and is liberated from the acylated form by condensation reactions involving acetyl-coenzyme A. This turnover explains why coenzyme A does not appear on the balance equation of β-oxidation, and provides a beautiful example of the catalytic functioning of coenzyme A in the living organism.

Ion-Exchange Chromatography of Guanidino Amino-acids from Synthetically Modified Gelatin

Elution chromatography of amino-acids on columns of 'Dowex 50' by the method of Moore and Stein[1] has proved a versatile technique for the analysis of biological materials[2-4]. Application of the method to chemically modified proteins has received little attention. The present investigation, in which it has been used to separate two amino-acids, considered to be homoarginine[5] and hydroxyhomoarginine, from hydrolysates of a guanidated gelatin, illustrates its power in this connexion.

The parent gelatin (17·9 per cent nitrogen), prepared from cattle hide after prolonged treatment with lime[6], was guanidated[7] by treatment with O-methyl isourea at *p*H 10–12. The guanidino gelatin (18·7 per cent nitrogen) had an isoelectric point, determined by the method of Janus, Kenchington and Ward[8], at *p*H 4·91, identical with that of the original gelatin, whereas its titration curve showed almost complete removal of ε-amino-groups. This would suggest conversion of the ε-amino-groups to guanidino-groups which, if complete, would give rise to an increase in total nitrogen of 0·87 per cent.

The gelatin and the guanidated product were de-ionized[8] with mixed-bed ion-exchange resins to remove all small ions and hydrolysed in sealed tubes with 6 *N* hydrochloric acid at 100° for 24 hr. The hydrolysates were chromatographed on 15 cm. × 0·9 cm. columns of 'Dowex 50' and eluted with 0·1 *M* sodium citrate, *p*H 4·95 for the first 25 ml. The elution curve of the gelatin (Fig. 1,*a*), in which the actual optical density of the test solution from each fraction is plotted against eluant volume, showed peaks corresponding to hydroxylysine, histidine, ornithine, lysine, ammonia and arginine. The asymmetry of the hydroxylysine peak was attributed to partial separation of the diastereoisomers[9]. The small ornithine peak partially merged into the leading edge of the lysine peak. This gelatin contained an abnormally large proportion of ornithine, formed by alkaline decomposition of guanidino-groups during manufacture. Collagen and acid-process[6] gelatins have been shown to contain no ornithine[10], whereas gelatins prepared after short lime treatments have small amounts.

The chromatogram of the guanidino gelatin (Fig. 1,*b*) showed almost complete absence of hydroxylysine, ornithine and lysine, increased arginine and the appearance of two new peaks. The first of these peaks, emerging between ammonia and arginine, was attributed to hydroxyhomoarginine, formed by guanidation of hydroxylysine. The peak emerging after arginine was considered to be homoarginine derived from lysine. The high and variable blank, in the region of the ammonia peak, due to emergence of ammonia accumulated from the buffer solutions, necessitated the removal of ammonia from alternate fractions to permit accurate estimation of hydroxyhomoarginine. The 1-ml. fractions were brought to *p*H 11·5 by addition of 0·051 ml. of *N* sodium hydroxide and ammonia was removed by evacuation at 15 mm. pressure for 4 hr. The fractions were then brought to *p*H 5·0 by addition of 0·097 ml. of 2 *N* hydrochloric acid before addition of ninhydrin reagent[11].

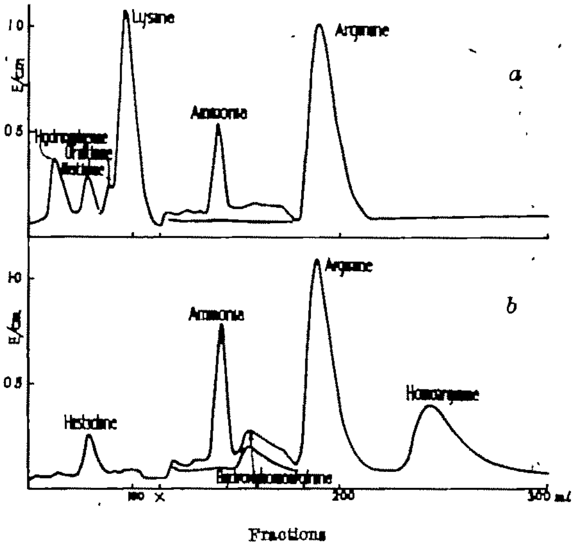

Fig. 1. Elution curve from 15 cm. × 0·9 cm. columns of 'Dowex 50' of hydrolysates of (*a*) 11·07 mgm. of gelatin, and (*b*) 11·07 mgm. of guanidated gelatin. The lower curve for fractions 120–180 indicates values obtained after removal of ammonia. The eluant buffer was changed from *p*H 6·75, 0·1 *M* sodium phosphate to *p*H 6·50, 0·2 *M* sodium citrate at the point marked *X* (115 ml.)

The contents of basic amino-acids of the gelatins are shown in Table 1. The 'colour yields'[11] of homoarginine and hydroxyhomoarginine were assumed to be the same as for arginine. The sum of the hydroxyhomoarginine and residual hydroxylysine of the guanidino gelatin is rather less than the original hydroxylysine content. This may be due to errors in the integration of the small hydroxylysine peak, arising from uncertainty in the position of the base line. Rather lower hydroxylysine values have been obtained with other gelatins[10]. The increase in the arginine content exceeds what would be expected from guanidation of ornithine. Errors in the estimation of ornithine are substantial, although these do not affect the combined figure for lysine and ornithine. The sum of the homoarginine, the increase in arginine and the residual lysine of the guanidated gelatin (35·0 residues per 10^5) agrees with the original total of ornithine and lysine (33·9 per 10^5), confirming that the discrepancies arose from the analysis of the overlapping peaks.

Arginine, homoarginine and hydroxyhomoarginine all give rise to asymmetrical peaks, each having a gradually falling trailing edge which appears to be

Table 1. Content of Basic Amino-acid Residues and Amide Nitrogen of a Limed Hide Gelatin, before and after Guanidation

characteristic of the guanidino-group. The sharp separation of arginine and homoarginine, each of which contains the same three ionizable groups and which differ only by one carbon atom in chain-length, illustrates the high resolution of basic amino-acids on 15-cm. columns of 'Dowex 50', eluted with nearly neutral buffers. Substitution of a hydroxy-group in homoarginine has the effect of causing an earlier emergence of the hydroxy amino-acid, a result also shown by the pairs lysine and hydroxylysine and alanine and serine.

Colour Reaction for Deoxyribose Compounds

THE two most commonly used methods for detecting deoxyribose compounds are the diphenylamine reaction[1] and the cysteine–sulphuric acid method[2,3], both originally discovered by Dische. Overend and Stacey[4] have made the most recent survey of the usefulness of these methods. Both methods suffer from the same fault, that neither measures pyrimidine-bound deoxyribose quantitatively. Brody[5] has used the cysteine–sulphuric acid method under conditions of precise temperature control for the quantitative determination of deoxyribose nucleic acid. It was not determined whether or not the pyrimidine-bound deoxyribose compounds were as chromogenic as the purine-bound sugars. The observations presented here show that the method can be employed for a variety of compounds containing deoxyribose.

The only change from the description by Brody was to decrease the final volume from 5·55 ml. to 3·33 ml., and the amounts of reagents used were reduced accordingly. The intensity of colour that developed was determined in the Beckman spectrophotometer at 474 mμ. Assuming that each mole of deoxyribose is quantitatively converted to the chromogen, Table 1 shows the apparent molar extinction coefficient of this chromogen as derived from tests with a variety of compounds containing deoxyribose. Within experimental error, the observed molar extinction coefficient is the same. It appears, therefore, that pyrimidine-bound deoxyribose reacts as well, quantitatively, as purine-bound deoxyribose. One can therefore use this method to determine the total deoxyribose content of a given sample. One can also determine the amount of purine-bound and pyrimidine-bound deoxyribose in any sample by a combination of the diphenylamine reaction and the cysteine–sulphuric acid method as described by Brody.

Table 1. REACTION OF DEOXYRIBOSE COMPOUNDS IN THE CYSTEINE–SULPHURIC ACID METHOD.

The test was carried out under the conditions described in the text. 50 μgm. of each substance was used, and the apparent molar extinction coefficient calculated from the value obtained

Substance	Apparent molar extinction coefficient of the chromogen (× 10⁴)
Adenine deoxyriboside	1·6
Thymidine	1·5
Cytosine deoxyriboside	1·3
Deoxyguanylic acid	1·4
Deoxyadenylic acid	1·3
Thymidylic acid	1·4
Thymidine diphosphate*	1·5
Deoxycytidylic acid	1·5
Thymus deoxyribonucleic acid†	1·4

* A commercial sample obtained from the California Foundation for Biochemical Research, Los Angeles, Calif.

† A commercial sample obtained from General Biochemicals, Inc., Chagrin Falls, Ohio. The apparent molar extinction coefficient was calculated on the basis of the composition of the deoxyribonucleic acid being a statistical tetranucleotide.

Correlation between Endogenous Auxin and its Destruction *In vivo* by 2:4-Dichlorophenoxyacetic Acid in Plants

SEVERAL investigators have recently pointed out the accelerating effect of 2:4-dichlorophenoxyacetic acid (2,4-D) on the destruction of auxin in dicotyledonous plants[1–3]. In addition, one group[3] has revealed that the opposite effect prevails in oat coleoptile sections, that is, 2,4-D effects a prevention or 'sparing action' of the previously reported destruction of indolylacetic acid in oat coleoptiles[4].

Experiments *in vitro* using etiolated oat coleoptile, pea epicotyl and sunflower hypocotyl sections (3 mm.), have shown that these two phenomena do indeed occur under similarly controlled conditions. Table 1 indicates that 2,4-D in increasing concentrations causes a continuously retarded destruction of added indolylacetic acid (50 mgm./l.) with oat sections. The opposite is shown for the pea and sunflower sections.

Next, intact plants grown in 'Terralite' were sprayed *in vivo* in the greenhouse and in the *Avena* dark room with 1,000 p.p.m. (4 × 10^{-3} *M* of sodium salt) of 2,4-D and allowed to stand 12–48 hr. (or longer for beans). Plant parts, exclusive of leaves, were extracted in the cold room (0–2° C.) with two successive portions of wet, peroxide-free ether over a 16-hr. period. The extracts were then made up in the usual manner for use in the Went *Avena* assay.

The results, as shown in Table 2, indicate that there is fairly good correlation between the previously cited effect of 2,4-D on auxin destruction (Table 1)

Table 1. Time in hours to cause complete destruction of indolylacetic acid (50 mgm./l.) in 30 sections of 3 mm. length (total volume of medium 12 c.c.). Phosphate buffer, pH 6·5. Continuous shaking at 110 oscillations per minute at 30° C

Species	Concentration of 2,4-D (p.p.m.) 0	250	500	1,000
Oat	4·5	5·0	6·0	9·0
Pea	6·0	4·5	4·5	6·0*
Sunflower	4·0	3·5	3·25	4·0*

* Destruction possibly inhibited by disorganization of the tissues in the sections due to high concentration of 2,4-D.

Table 2. Endogenous auxin in plants treated with 2,4-D at 1,000 p.p.m. (after 48 hr.) Tested by *Avena* assay of Went

Species	Wet wt. (gm.)	Curvature of *Avena* coleoptiles Untreated	Treated	Standard IAA 25 γ/l.
Oat*	2·0	7·2	8·2	11·7
Sunflower	5·0	13·8†	7·8†	9·7
Pea	5·0	9·0	5·8	10·0
Bean	2·3	73·0	16·4‡	av. 10·5

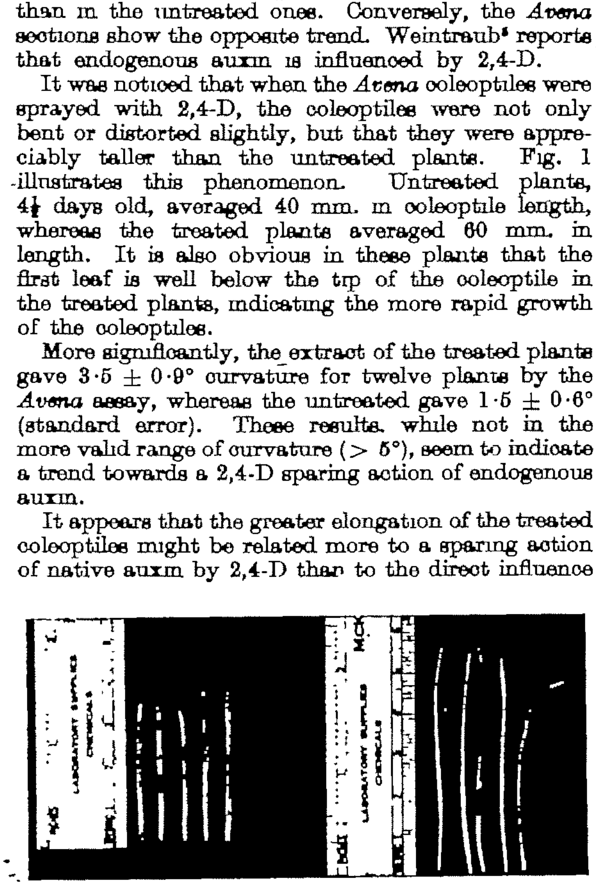
* Average of four separate runs made at widely different times
† One run out of three gave untreated, 13·5°; treated, 8·8°
‡ These plants were treated with 10, 100 and 1,000 p.p.m. 2,4-D; results: 52°, 18°, 16°, respectively.

and the amount of endogenous auxin remaining in the plant sections. It is obvious that the dicotyledons are definitely influenced by 2,4-D either in their auxin synthesis or in its destruction, since the levels of auxin in the treated plants are significantly lower than in the untreated ones. Conversely, the *Avena* sections show the opposite trend. Weintraub[5] reports that endogenous auxin is influenced by 2,4-D.

It was noticed that when the *Avena* coleoptiles were sprayed with 2,4-D, the coleoptiles were not only bent or distorted slightly, but that they were appreciably taller than the untreated plants. Fig. 1 illustrates this phenomenon. Untreated plants, 4½ days old, averaged 40 mm. in coleoptile length, whereas the treated plants averaged 60 mm. in length. It is also obvious in these plants that the first leaf is well below the tip of the coleoptile in the treated plants, indicating the more rapid growth of the coleoptiles.

More significantly, the extract of the treated plants gave 3·5 ± 0·9° curvature for twelve plants by the *Avena* assay, whereas the untreated gave 1·5 ± 0·6° (standard error). These results, while not in the more valid range of curvature (> 5°), seem to indicate a trend towards a 2,4-D sparing action of endogenous auxin.

It appears that the greater elongation of the treated coleoptiles might be related more to a sparing action of native auxin by 2,4-D than to the direct influence of the latter on cellular elongation. Sufficient evidence exists that this could be the possible explanation, just as it appears to be the cause for the continued acceleration of respiration in the coleoptile sections under the influence of added indolylacetic acid and 2,4-D[3]. Experiments are under way, using decapitated and non-decapitated coleoptiles, in an attempt to elucidate whether the increased growth is a result of the 2,4-D or native auxin.



Untreated

Treated with 1,000 p.p.m. 2,4-D

Fig. 1. *Avena* coleoptiles (sample of five out of c. 200) untreated and treated with 2,4-D, the latter after 36 hr. exposure to 1,000 p.p.m. All plants grown in *Avena* 'dark' room

Thus, it is possible that these observations might bring about a new interpretation of some of the previously unexplained results involving the use of 2,4-D on plants.

Some Cytological Observations on the Delayed Effect of Mustard Gas

IN the course of a quantitative study of re-arrangements induced by mustard gas in *Drosophila melanogaster*[1], 757 progeny of treated males have so far been analysed by the salivary gland method. Among sixteen structural changes, one was a mosaic for two inversions involving separately the *X* and *3R* chromosomes. Mosaic glands have also been found in the progeny of X-irradiated males[2]; the special features of the present case are: (1) mosaicism for two independent changes and (2) the fact that in any one nucleus both changes were either present or absent. Of thirty-eight nuclei analysed, seventeen contained both inversions, twenty-one neither. Since in the preparation of the slides only one larva was used at a time, a mixture of two sets of glands on the same slide could not occur. The possibility that nuclei in unanalysed parts of the larva may have contained only one of the inversions cannot be ruled out; but the simplest interpretation is that both changes arose simultaneously either immediately after fertilization or through delayed effect at a later mitosis. The first alternative requires that in both *X* and *3R* only one of the broken sister chromatids formed an inversion, while the other was restituted in the old order, and that at anaphase the two inverted chromatids segregated to the same pole. The second alternative dispenses with these requirements and is therefore rather more probable. It suggests that conditions which affect the nucleus as a whole may result in the simultaneous opening up of latent breaks in several chromosomes.

Another structural change consisted of a reversed repeat involving regions 7 and 8 of the *X*-chromosome. Repeats, whether in reverse or normal order, which occur in the progeny of treated males, must have arisen as chromatid changes. The individuals containing them presumably are mosaics, carrying the duplication in part of their cells and the complementary deficiency in the remainder. With a favourable distribution of the two types of cells, this kind of mosaicism has indeed been observed after treatment with X-rays[2,3] and mustard gas[4]; in other cases the deficiency may not have been accessible to analysis, or it may not have given rise to viable tissue.

The origin of such a duplication-deficiency in the newly fertilized zygote need not involve a true delayed effect, but only differences in the way in which the broken sister chromatids undergo reunion. X-ray duplications presumably arise by this mechanism. Their frequency in Bauer's experiments[5] was seven duplications out of 688 structural changes; Kaufmann[6] found a similar frequency. After mustard gas treatment of males, Mehtab[7] obtained two reversed repeats among eleven structural changes. Added to the present sample, this gives a frequency of three reversed repeats among twenty-seven changes, a markedly higher value than that found for X-rays. It suggests that some special effect of chemical treatment, probably its after-effect, favours the occurrence of repeats. It should also be noted that reverse repeats cannot arise without previous breakage of the chromosomes; the frequent occurrence of this type of change after mustard gas treatment indicates that at least many of the structural changes induced by mustard gas cannot be explained by non-homologous crossing-over (see ref. 8).

Inability of Acetylcholine Antagonists to protect Mice against the Toxicity of 'Tensilon'

The anticurare action of 'Tensilon' (3-hydroxy-*N*-dimethylethylanilinium bromide) was considered by Randall[1,2] not to depend upon cholinesterase inhibition. Hobbiger[3] and Hall and Parkes[4] showed, however, that 'Tensilon' does not reverse neuromuscular block after treatment of the preparation with tetraethyl pyrophosphate, implying the necessity of active cholinesterase for the effect.

We have recently described the protection afforded to mice against the toxicity of anticholinesterase drugs by antagonists of acetylcholine[5]. Animals were injected intravenously with atropine, 10 mgm./kgm., tubocurarine, 0·1 mgm./kgm., or hexamethonium, 40 mgm./kgm., and the decrease in intravenous toxicity of simultaneously injected neostigmine or tetraethyl pyrophosphate may be quoted as examples:

	Neostigmine	Tetraethyl pyrophosphate
LD 50 alone	0·306 mgm./kgm	0·2 mgm./kgm.
LD 50 with atropine	0·66 "	0·56 "
LD 50 with tubocurarine	4·19 "	0·73 "
LD 50 with hexamethonium	4·5 "	0·666 "

Corresponding values obtained with 'Tensilon' have shown, however, that these antagonists provided no protection at all against the toxicity of this substance.

LD 50 of 'Tensilon' alone	18·6 (17·6–19·6) mgm./kgm.
LD 50 with atropine	17·4 (16·35–18·5) "
LD 50 with tubocurarine	c. 20 mgm./kgm. (2 dose-levels only)
LD 50 with hexamethonium	17·6 (16·45–18·8) mgm./kgm.

These results would certainly seem to be inconsistent with the participation of cholinesterase inhibition or the augmentation of cholinergic function in the toxicity of 'Tensilon'.

Toxicity of Erythromycin

In the course of experiments using young guinea pigs as test animals, it was found that erythromycin given orally or intraperitoneally caused the animals to look ill after two to three days, with ruffled fur, anorexia, disinclination to move and subnormal temperature, followed by death on the sixth to eighth day with emaciation and signs of diarrhœa. No obvious common cause of death could be found macroscopically or microscopically in sections of liver, spleen, kidney or lung, although occasionally liver necrosis and renal tubular degeneration were seen, accompanied by albuminuria, red cells and casts in the urine and slightly raised blood urea.

It may be seen from Table 1 that, with small numbers of animals, toxicity is independent of age (weight) of the animal or the type of preparation, but is related to the dosage and route of administration, that is, blood and tissue concentration. Guinea pigs weighing 160 gm. were given erythromycin orally or intraperitoneally in doses of 62·5 mgm./kgm. at 12-hr. intervals, and killed 2 hr. after the third dose. The serum and liver concentrations were 2 μgm./ml. and 16 μgm./ml. respectively after injection, and 0·1–0·2 μgm./ml. and 0·9 μgm./ml. orally. A high degree of toxicity is indicated by the lethality of 500–600 μgm./kgm. injected in one dose, where the blood and tissue concentrations must have been extremely low and transient. Guinea pigs injected intraperitoneally with 100 - mgm. erythromycin (625 mgm./kgm.) died in 3–6 hr. Doses used as in Table 1 caused death in 3–12 days, averaging 7·1 ± 0·2 days for forty-five guinea pigs.

Hamsters of 50–60 gm. weight treated intraperitoneally with 30–200 mgm./kgm. erythromycin in one or more doses also died after approximately thirteen days, with a terminal illness closely resembling that of guinea pigs.

This delayed toxicity has not been recorded in other work on erythromycin, where the oral *LD*50

Table 1. Toxicity of Erythromycin for Guinea Pigs

Potent Diphtheria Toxin within the Cells of *C. diphtheriae*

All the exotoxins except diphtheria toxin have been demonstrated within the bacterial cells in a very early stage of culture. So far as diphtheria toxin is concerned, it has been postulated, but never proved, that the exotoxin is formed within the cell. I have, however, previously deduced the possibility of temporary existence of the toxin within the cell from the morphological and biochemical characteristics of this organism[1,2]. I believe that the failure to show the presence of the toxin was due to the fact that physiologically young cells of *C. diphtheriae*, however early they might be harvested, could not be obtained when static culture was used.

By using shaking cultures, I have obtained physiologically young cells containing the highest toxicities ever found. The shaker rotated at the rate of approximately 130 cycles per min. with an amplitude of 13 cm. Each flask of 200 ml. capacity contained 20 ml. of Pope's medium. A series of flasks was sampled at the three stages of growth: logarithmic phase, that of negative acceleration, and maximum stationary phase. The bacilli harvested from each flask were washed with water, suspended in 0·01 per cent merthiolate solution and then tested for toxicities by subcutaneous or intraperitoneal injection. Toxicities of the bacilli harvested at the three stages, such as, for example, 12, 15 and 35 hr. intervals, are compared in Table 1.

Table 1

	Incubation time (hr.)	Bacterial growth (mgm. *N*/20 ml.)	*Lf*/ml. (in culture filtrate)	*MLD*/mgm. *N*
No. 1	12	7·7	0	< 25
No. 2	15	11·8	15	> 300
No. 3	35	13·9	55*	< 25

* Maximum titre produced in this medium. As the toxin titre in the filtrate already reached to 50 *Lf* at the 24th hour, almost all the toxin produced within the cell is thought to be excreted outside in 24 hr.

Table 2

MLD/gm. (dry weight)	Authors
75	Prigge, R. (ref. 3)
1	Bieler, M. (ref. 4)
21,400*	(in this report)

* Cell suspension of *C. diphtheriae* corresponding to 1 mgm. nitrogen was dried at 60° C., measured for its weight, and proved to be 14 mgm.; *MLD* 300 in Table 1 was multiplied by 1,000/14.

It was found that both the very young and the very old bacilli contained little toxin within the cells, and the toxin content of the bacilli was highest in the period of decelerating rate of multiplication. This result was different from that for other exotoxins, because the bacilli harvested in the logarithmic phase, for example, at the 12th hour (see Table 1), showed remarkably lower toxicity than in the period of decelerating growth-rate. About 200–350 *MLD* per mgm. nitrogen was usually obtained from the bacilli during the period of decreasing growth-rate, but once the value of 750 *MLD* per mgm. nitrogen was obtained.

It is inevitable that the toxin content of the bacilli in this period is variable because toxin production and excretion occur together for such a short time. My titre is compared with the highest toxicities reported by other authors in Table 2. The toxicity I obtained was identified by the findings at adrenal glands of injected guinea pigs and by the neutralization test by diphtheria antitoxin. Thus, this work shows that diphtheria toxin is formed within the cell.

I thank Prof. T. Tani for his encouragement and guidance.

Growth- and Inhibiting-Substances in Relation to the Rest Period of the Potato Tuber

In an investigation of the growth- and inhibiting-substances in the potato tuber in relation to its rest period, Hemberg[1] has shown that potato peelings contain an acid and a neutral growth-substance in addition to acid and neutral growth-inhibiting-substances. On the basis of molecular weight determinations by diffusion through agar, and sensitivity towards acid and alkali, he concluded that the acid growth-substance is in all likelihood indole-3-acetic acid. In addition, he was able to show that the neutral growth-substance could be converted to the acid growth-substance by enzyme action, and concluded that the former is probably indole-3-acetaldehyde. The disappearance of the acid growth-inhibiting substance from the potato tuber towards the end of the rest period is considered by Hemberg to be the primary cause of the breaking of dormancy in the potato tuber.

The purpose of the experiments reported here was to determine and possibly to identify the growth- and inhibiting-substances present in the potato tuber by the method of paper chromatography, followed by the *Avena* bioassay as originally described by Luckwill[1] and Bennet-Clark *et al.*[3]. The methods used were as follows. Peelings from potatoes of the variety Kennebec, stored at room temperature in the dark, were extracted at regular intervals from the time the potatoes were lifted up to the time of sprouting eight weeks later. Peelings were cut into small pieces, covered with peroxide-free ether, and placed in a refrigerator at 4° C. for 48 hr. Ether extracts were then separated into neutral and acid fractions according to the method of Larsen[4]. The final ether fractions were concentrated to small volume and applied as spots to the starting line of chromatograms (Whatman No. 1 paper), run for $3\frac{1}{2}$ hr. at 30° C. with *n*-butanol saturated with $2N$ ammonia as solvent. The ascending test-tube method as described by Rockland and Dunn[5] was employed. Bioassay of developed chromatograms was carried out by the *Avena* straight-growth method using a local oat variety, *Avena byzantina* var. Jongensklip, as test material. Developed chromatograms were divided into fifteen 1-cm. segments, each covered with 1 ml. distilled water in small specimen tubes, and ten 3·3-mm. subapical oat coleoptile sections floated on each eluate followed by incubation at 30° C. for 6 hr. The mean elongation of ten coleoptile sections expressed as a percentage of the original length was plotted against the position of the paper segments on the chromatograms as shown by histograms. Results obtained with the acid fractions of five potato peeling extracts taken at consecutive dates from the time the potatoes were lifted up to the time of sprouting are shown in Fig. 1. The results are purely qualitative, but give an indication of the relative growth-activity of the substances present in each extract. Dotted lines indicate the mean percentage elongation of control segments from blank chromatograms run concurrently, a difference of 2·4 per cent (2 × standard error) above or below the control being considered significant. The positions of the synthetic growth-substances indole-3-acetic acid (IAA), indole-3-butyric acid (IBA), indole-3-acetaldehyde (IAc) and indole-3-acetonitrile (IAN) run concurrently on similar chromatograms were marked by guide lines, and could be revealed as coloured spots by spraying chromatograms with Ehrlich's reagent (1 per cent *p*-aminobenzaldehyde in $1N$ hydrochloric acid). The respective R_F values for the above growth-substances were: indole-3-acetic acid, 0·28–0·30; indole-3-acetonitrile, 0·87–1·0; indole-3-butyric acid and indole-3-acetaldehyde, 0·40–0·42.

Based on a comparison of growth activity with that of guide spots of the synthetic compounds, all extracts apparently contain indole-3-acetic acid and a second acid growth-substance which is invariably separated from this region by a definite zone of inactivity on the chromatogram and could therefore not be ascribed to tailing of the indole-3-acetic acid spot. This second growth-substance occupies the same position on the chromatogram as both indole-3-butyric acid and indole-3-acetaldehyde. It is not an aldehyde, as it invariably occurs in the acid fraction of the extract and does not form an addition product with sodium bisulphite. Consequently it is suggested that this second growth-substance could possibly be indole-3-butyric acid. It will be noted that as dormancy is gradually broken, this second growth-substance shows a constant increase in activity relative to that of indole-3-acetic acid, and when sprouting commences its relative activity is even larger than that of the latter.

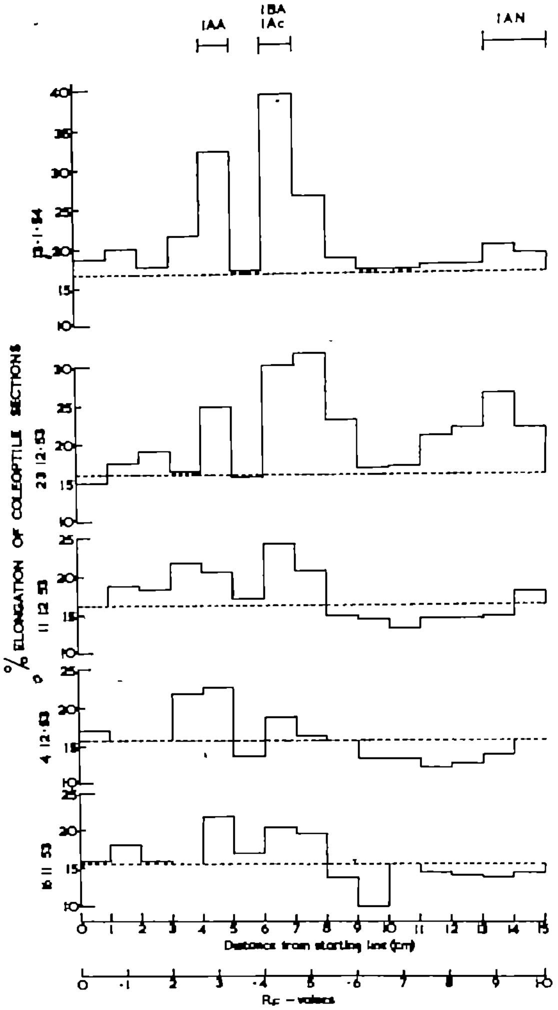

Fig. 1. Histograms showing coleoptile extension-growth in the presence of 1-cm. sections cut from chromatograms of the acid fraction of potato-peeling extracts. Bottom to top: consecutive dates from time potatoes were lifted up to time of sprouting. Dotted lines indicate extension growth of controls. Position of synthetic growth-substances shown by guide lines marked IAA, IAc, IBA and IAN

The presence of an acid inhibitor in the position 8–11 cm. (R_F 0·52–0·74) is strongly evident during the first five weeks, but gradually diminishes up to the time of sprouting, when it has entirely disappeared. However, as will be seen from the histograms, the disappearance of the inhibitor approximately three weeks (23.12.53) before sprouting is apparently associated with the appearance in the extracts of a third growth-substance which is not detectable in the earlier stages of dormancy. This third growth-substance occupies the same position on the chromatogram as synthetic indole-3-acetonitrile, and as the presence of that substance in potato tuber extracts has previously been reported by Bennet-Clark and Kefford[6], it is suggested that it is the same substance. In all extracts there are indications of a fourth growth-substance with an R_F value of 0·08–0·15. Bennet-Clark and Kefford[6], Lexander[7] and Terpstra[8] have reported a growth-substance which moves more slowly than indole-3-acetic acid with approximately similar R_F values. Recently, Stowe and Thimann[9] have suggested that this growth-substance is probably indole-3-pyruvic acid, which they have identified in maize endosperm. It would appear that here again our fourth growth-substance with low R_F may be indole-3-pyruvic acid.

Neutral fractions of potato peeling extracts assayed at the same time as the above gave indications of one or more inhibitors which do not, however, disappear at the end of the rest period. Except for the presence of the nitrile at the time it appears in the acid fraction, no other growth-substances were evident in the neutral fractions. The presence of the nitrile in both acid and neutral fractions is, according to Bennet-Clark and Kefford[6], due to its being carried over from ether into bicarbonate solution and back to ether on re-acidification during fractionation of the original extract. The neutral growth-substance of potato peelings described by Hemberg[1] may be identical with indole-3-acetonitrile as the latter can, like indole-3-acetaldehyde, be converted to indole-3-acetic acid[10].

From the point of view of dormancy, the above results support the theory of Hemberg[1] that the breaking of dormancy in the potato tuber is primarily due to the disappearance of an acid inhibitor. The simultaneous increased activity of both indole-3-acetic acid and indole-3-butyric acid with the disappearance of the acid inhibitor indicate that the latter may function as an anti-auxin or competitive inhibitor. As the disappearance of the acid inhibitor is associated with the appearance of a growth-substance which may be indole-3-acetonitrile, it is possible that the latter is also in some way connected with breaking of the rest period.

A detailed report of the above investigation will be published elsewhere.

Varietal Susceptibility of Brassicas to Molybdenum Deficiency

MOLYBDENUM deficiency under Irish conditions has previously been reported to occur in clovers and swede turnips[1]. During the 1953 season, a severe outbreak of whiptail on cauliflowers occurred on a commercial plot at one of the centres mentioned. The soil, which had an initial pH of 5·3, had received a dressing of 1¼ tons of ground limestone per acre as well as a dressing of superphosphate, muriate of potash and sulphate of ammonia at 5, 2 and 3 cwt. per acre respectively.

Severely affected	Moderately affected to slightly affected	Unaffected
Cauliflower : Cambridge No. 6 Cambridge No. 7 Self-protecting	Cauliflower : Yates Progress Autumn Giant Brussels sprouts : Cambridge No. 3 Cambridge No. 1 Broccoli : Early Feltham	Cauliflower : All-the-Year-Round Brussels sprouts : Masterpiece Cluseed Broccoli : Mid June 1949 May Wonder April Queen Cabbage : Primo Winningstad Rearguard Kale Savoy : Perfection Market Garden January King Sprouting Broccoli : Early Purple

Shortly after the plants were set out, severe symptoms of whiptail appeared on the varieties Cambridge No. 6 and Cambridge No. 7. The variety All-the-Year-Round, which had received identical cultural treatment, was not affected, though it did show some effects of manganese toxicity.

In another plot where a number of varieties of Brassicas were grown, the Cambridge varieties again showed a severe incidence of whiptail, whereas most other varieties of Brassicas were either unaffected or but slightly affected.

Duplicate plots of affected varieties were treated with sodium molybdate at 2 lb. and 4 lb. per acre; this treatment effected a considerable improvement and resulted in head formation where buttoning had not already taken place. The same varieties were sown on a similar soil type in 1954, and again the Cambridge varieties of cauliflower showed a pronounced susceptibility to whiptail, No. 6 being the most severely affected and No. 7 the least affected. Cambridge No. 5, which was sown in 1954 only, was also affected.

The soil in which the condition occurred showed a level of available molybdenum as determined by

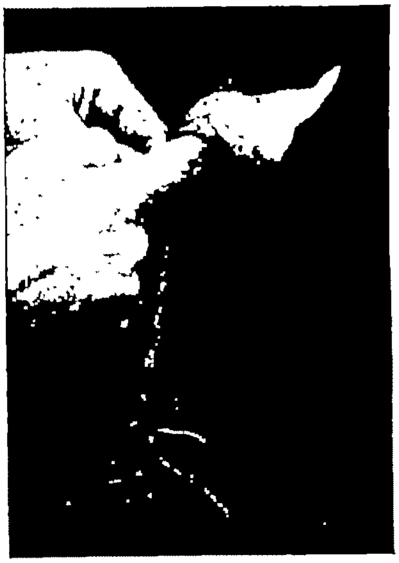

Fig. 1

the oxalate method to be in the region of 0·14 p.p.m.[2]. A symptom of the deficiency which does not appear to have been previously recorded is the production of bell-shaped leaves (Fig. 1). These would appear to result from the fusion of the lamina of basal leaves followed by abscission of the growing point. The level of molybdenum at which particular varieties of Brassicas become affected by whiptail is at present under investigation.

A Remarkable Disintegrative Effect of Skatole upon Certain Rumen Ciliate Protozoa

Hogg and Elliott[1] noted that indole and skatole were both highly toxic towards the aerobic free-living ciliate *Tetrahymena pyriformis*. A concentration of 0·01 per cent of indole, for example, killed all organisms in a vigorous culture in two hours, but these workers made no mention of any characteristic change in appearance of the cells. We have now shown that these substances are highly toxic to the anaerobic ciliates of the sheep's rumen, particularly the holotrichs (*Isotricha* and *Dasytricha*) and also *Ophryoscolex*. These ciliates had been separated from strained rumen contents, washed and maintained alive and active for several hours in a phosphate buffer (without antibiotic) at pH 7·2 as described by Heald, Sugden and Oxford[2]. On a molecular basis skatole was much more toxic than indole to the rumen ciliates; but if the comparison was made at concentrations near saturation in the buffer employed, indole being the more soluble compound, the respective effects upon the final appearance of the cells were almost equally spectacular. Briefly, not only did all ciliary motion cease in two hours at 37°, but also a phenomenon resembling a drastic mechanical disintegration took place. The outer pellicles of the holotrichs, and also of *Ophryoscolex*, were torn asunder with liberation of the internal contents of the cells, so that after gently shaking the tube, instead of the rapid re-formation of a layer of ciliates at the bottom below a clear supernatant, there was a dense uniform turbidity throughout due to the release of storage polysaccharide granules and other inclusions from the disrupted cells.

The effect is markedly similar to that due to the anionic detergent 'Teepol', as described by Oxford[3]; but since indole and skatole do not, of course, greatly lower the surface tension of the buffer, another explanation of their action has to be found. Any such explanation must take account of the following facts:

(1) The rapid disruptive effect is only exhibited near the saturation point, that is, c. 0·1 per cent for indole, and 0·025 per cent for skatole (c. 0·002 *M*) in the buffer employed. This applies also to those isomers of skatole which have so far been tested, namely, 2- and 7-methylindoles. These appear to have similar solubilities to skatole, which, however, acts much more rapidly than either of the others and produces a denser final turbidity.

(2) Isatin, which is also sparingly soluble in the buffer (c. 0·12 per cent), acts in a fashion very similar to indole. Aniline, however, is not highly toxic.

(3) More highly polar indole derivatives related to tryptophan, like tryptamine, tryptophanol and indole-3-acetic, -propionic and -butyric acids, are not highly toxic and have no disintegrative effect at pH 7 at a concentration of 0·1 per cent.

(4) The toxic effect of indole or skatole cannot be nullified by addition of tryptophan, serine, casein hydrolysate or glucose to the buffer.

It would appear that although a fairly close resemblance to the tryptophan structure, as in skatole, increases the disruptive power of these indole derivatives, the primary requisites for toxicity are physical, namely, slight water- and ready lipoid-solubility, and the absence of any strongly polar centre in the molecule. Since indole—and perhaps skatole—are possible products of bacterial degradation of protein in the rumen, the presence of these and similar compounds may provide an explanation for some of the puzzling variations in density and composition of ciliate population in the normal rumen which undoubtedly occur from time to time.

Our thanks are due to Prof. H. N. Rydon, Department of Industrial Chemistry, College of Technology, Manchester 1, for a gift of a specimen of 7-methylindole.

Goitre and the Iodine Content of Cow's Milk

During a recent systematic investigation in the Netherlands, it was found that at all seasons marked differences existed between the iodine contents of milk supplied to creameries in goitrous and non-goitrous areas. The location of these areas, in general, corresponds with those found by investigations on thyroid enlargement and thyroid histology in humans and farm animals[1].

In addition to the local differences, a seasonal variation, roughly corresponding inversely to the milk yield, was observed. Therefore, it is essential to make the period of collection of the milk samples as short as possible in order to get strictly comparable results. In the present investigation, some hundreds of samples were collected each time on the same day. The variation of iodine content with time has often been disregarded in previous investigations, and as a result the distinction of goitrous from non-goitrous regions by examination of the milk supply has been needlessly obscured.

In Table 1 a summary of the iodine values, obtained with our method of analysis[2], is recorded.

For a general survey of the iodine status of cattle, the determination of iodine in the milk offers distinct advantages over determination in the blood or histological investigation of thyroid glands. Collection of milk samples is comparatively easy, and the large number of contributing animals living in the same conditions rules out factors of individual variation in quite a simple way.

Table 1

Area	No. of creameries (N)	Mean iodine content of milk: ($\bar{I}$) Summer (in μgm./100 ml.)	Winter
Goitrous	78	0·97 (σ* = 0·026)	2·06 (σ = 0·053)
Transitional	37	1·38 (σ = 0·047)	3·21 (σ = 0·13)
Non-goitrous	43	2·11 (σ = 0·077)	4·88 (σ = 0·15)
Extreme coastal	14	3·43 (σ = 0·21)	8·85 (σ = 0·59)

* $\sigma = \sqrt{\frac{\Sigma(I - \bar{I})^2}{N(N-1)}}$; in which I stands for the actual iodine contents.

I wish to thank Prof. E. Brouwer for suggesting this work, a detailed account of which will be published elsewhere.

Analysis of Milk in Deficiency Diseases and Intoxications of Cattle

IN the diagnosis of deficiency and of poisoning of animals, one generally relies on the chemical analysis of the classical substrates like blood and liver. Eventually the composition of the food is also taken into consideration. It is surprising that in farm animals, and even in lactating animals, general methods largely derived from medical routine are used and that, for example, the milk as a substrate has been neglected.

Nevertheless, in the Netherlands some successful attempts have been made to obtain information by other methods. Thus examination of urine has been shown to offer an insight into the ingestion of potassium, sodium, chlorine and sulphate by cows at pasture or stall-fed[1]. Information about iodine metabolism may be obtained by histological examination of thyroid glands of newborn calves[2]. (In contrast to the situation for other farm animals and humans, it is possible to collect large quantities of thyroid glands because approximately 45 per cent of all newborn calves are slaughtered a few days after birth.)

We believe that more precise information about iodine ingestion can be obtained by the analysis of milk samples. In the preceding communication, the occurrence of marked differences in the iodine content of cow's milk is reported, reflecting the goitre status in cattle.

Because iodine is not the only variable milk constituent, we suggest the chemical analysis of milk as a method in all cases in which a distinct variability in milk composition depending on food intake has been established. This should include the determination of vitamins[3] and trace elements like iodine and copper[4] in deficiency, and of manganese[5], zinc[5], molybdenum[6], arsenic[6], lead[7], insecticides[8] and other toxic substances in excess (a review of the latter is in preparation).

For a quantitative evaluation of the results of the analyses, undoubtedly some fundamental investigations remain to be carried out in connexion with the influence of the milk yield, stage of lactation, etc. In a research programme requiring a preliminary survey of the availability of the above-mentioned compounds in the food of milking cows over a large number of homogeneous districts, much of the individual variation can be ruled out by examining milk samples obtained from creameries in these districts (see preceding communication).

Elements such as molybdenum and manganese, which may be constituents of the metal of milk containers, etc., are not likely[6] to contaminate the milk to the same extent as surface coatings, like zinc, copper and nickel.

Autonomous Differentiation of some Chick Neurons isolated in Chorion-Allantoic Grafts

THE problem of differentiation of neurons consists in identifying the factors, of intrinsic or extrinsic nature, that act upon the neural embryonic cells and the time and modality of their action.

The methods of studying the isolated development of neuroblasts (ectopic transplantation, explantation, destruction of connexions or of peripheral organs, etc.) have been employed with clear results for the Mauthner cells of amphibians[1]. Extending these researches to other types of neurons, I have taken into consideration different neurons of the chick, isolating various fragments of the embryonal neuraxis by means of implants into the allantochorion membrane[2].

The purpose of this brief account is to illustrate results on the recurrent axon neurons of the optic lobes and of the Purkinje cells of the cerebellum of the chick in very small implants.

It has been demonstrated[3] that in isolated fragments consisting of about half the embryonic tectum (at the stage of the primary optic vesicle), after the nineteenth day of incubation the recurrent axon neurons are perfectly well differentiated (Fig. 1,*B*); the presence in these isolated fragments of the recurrent axons is the best proof that the peculiar orientation of these fibres is not determined by antagonistic neurobiotactic fields of physiological activity of any kind (as was supposed by Leghissa, 1946).

In implanted fragments of about one-third or one-fourth part of one-half of the tectum, we observed various degrees of deformation of the tectum cells due to great disturbance by the vessels invading the implant and especially to the abnormal organization of the fragment, which tend to reach a ball-like form. These conditions and the limited growing space are factors that make normal differentiation

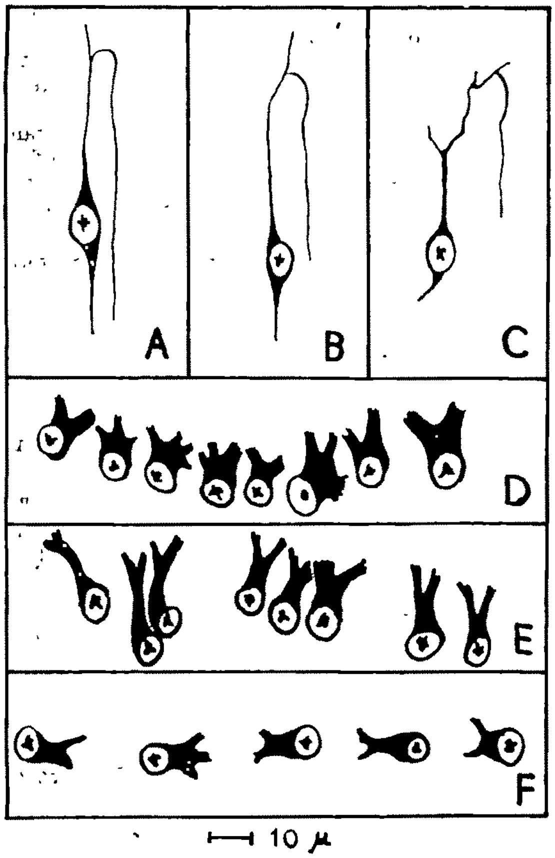

Fig. 1. Camera lucida drawings of some spindle-shaped tectal cells with recurrent axon and of some Purkinje cells of the cerebellum of a normal chick after the nineteenth day of incubation (*A*,*D*), compared with cells of the same age isolated at the primary optic vesicle stage and implanted in the allanto-chorionic membrane; *B*,*E*, from a fragment equal to half the organ (tectum or cerebellum) and *C*,*F*, from a fragment equal to about one-fourth of one-half (see text)

impossible. Nevertheless, even in the smallest bits of tissue these neurons tend to become spindle-shaped, and the axon tends to direct itself in a recurrent way. Very often in these conditions the curve of the axon is wider than the normal, and some collateral branches are present (Fig. 1,*C*).

Similar experiments with cerebellar fragments show Purkinje cells to be very well ordered in a single layer and with the dendritic lobe normally oriented towards the external surface (Fig. 1,*E*). Also, in very small fragments with few Purkinje cells and without any organization of surfaces, the cells are arranged in a single layer and distributed at a regular distance from each other; but the dendritic pole, still clearly evident, is not oriented in a unique direction owing to the absence of a directional organization of the fragment, but is indifferently directed against the neighbouring cell (Fig. 1,*F*).

These experiments lead us to the conclusion that the shape and form of the neurons are intrinsically determined, at the moment of histogenetical determination, and completely independent of any physiological activity. Also the orientation of fibres (for example, the recurrent axons of tectal spindle cells) is to be considered as an intrinsically determined susceptibility of the fibre to react specifically to morphological (not physiological) orientating factors such as the polarity of the fragment and the polarity of the cell itself.

The fundamental importance of physiological factors is shown later by many results, among which hyperplasia is especially evident, when the differentiated cells are physiologically connected.

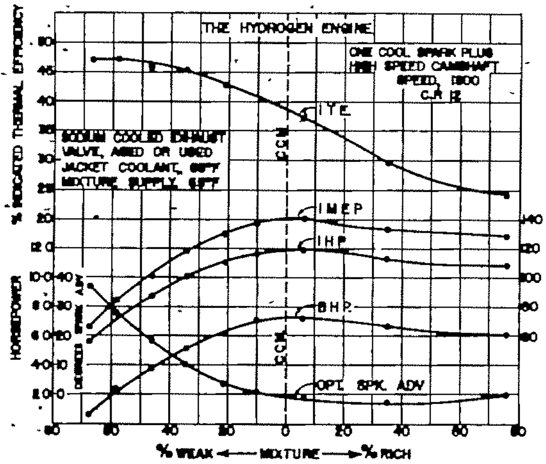
The Hydrogen Engine

It has always been stated by others that it is necessary to use weak mixtures with air when hydrogen is used as a fuel for Otto-cycle engines. Thus Ricardo[1] reported that "if an attempt were made to run with a rich hydrogen–air mixture violent pre-ignition occurred, accompanied by firing back in the carburettor, which rendered further running impossible. Even with the compression ratio lowered to 3·8 : 1, the same thing occurred". Similar effects were obtained later by A. F. Burstall[2] when using a Ricardo *E*.35 engine in the Engineering Laboratory, Cambridge, and still later by Egerton, Smith and Ubbelohde[3], when using an ethyl knock-testing engine for experiments at Oxford.

The igniting effect is generally described as pre-ignition, but by some observers as 'detonation'. Downs, Walsh and Wheeler[4], as a result of experiments with an *E*.6 Ricardo engine, state that "in most cases, owing to the extreme ease with which it ignites, a mixture strength richer than about 25 to 30% weaker than chemically correct cannot be used. If the attempt is made to run with a richer mixture, self-ignition occurs so early on the compression stroke that the mixture is eventually ignited in the induction manifold". Similar igniting effects were obtained by Anzilotti and associates when using a *C.F.R.* engine in a Du Pont Laboratory, Wilmington, U.S.A.

We have found as a result of experiments with a *C.F.R.* engine that premature ignition of hydrogen–air mixtures occurs solely when the exhaust valve or the ceramic core of the spark plug attains an igniting temperature in respect of the mixture, and otherwise only by nuclear ignition due to finely divided carbon produced by the decomposition of lubricating oil. Thus by reducing the temperatures of the spark plug core and the exhaust valve, and avoiding the passage of lubricating oil into the combustion chamber at an excessive rate, it has been possible to run the engine at speeds rising to 1,800 r.p.m., and with a compression ratio as high as 12 : 1. A maximum of 47½ per cent has been obtained for indicated thermal efficiency, and one of 146 lb./sq. in. for indicated mean effective pressure was obtained at 1,500 r.p.m. These values exceed those recorded in the literature of the subject by a wide margin. To obtain still higher values would require an engine designed to avoid leakage of hydrogen past the piston, and a combustion chamber having a reduced surface-to-volume ratio. Typical performance results as obtained with a speed of 1,800 r.p.m. and a compression ratio of 12 : 1 for hydrogen–air mixtures ranging from nearly 80 per cent weak to more than 70 per cent rich are given in Fig. 1.

Our experimental results are not in agreement with the conclusions of Downs, Walsh and Wheeler, that



Engine speed, 1,800 r.p.m.; compression ratio, 12 : 1

self-ignition arising from a chain reaction occurs in an engine.

The experiments were carried out on behalf of the Defence Research Board (Canada), in the Department of Mechanical Engineering, University of Toronto, with the co-operation of Prof. E. A. Allcut, head of the Department, and will be described in detail in a Canadian journal.

Ultrasonic Absorption in Castor Oil, Carbon Disulphide, Benzene and Xylene

ULTRASONIC absorption in some liquids has been measured by the method of heat development. The apparatus and its working was designed in such a way as to make it free from error due to the variation of generator power and also due to reflexion. A 3 Mc./s., 100-W. quartz generator produced the beam in liquid kerosine, contained in a vessel with cork paddings at the ends. In a small double-walled metallic vessel with asbestos packing, having a suitable coat of cement, two mica windows of 0·002 cm. thickness were fitted to allow the beam to pass in and out again after absorption. Two such vessels were made with exactly similar windows and different separations; the separations of windows were 3·6 cm. and 4·6 cm. Arrangements were made to place the front windows in the same relative position with respect to the quartz. The rise in temperature in these fairly non-conducting trap vessels, with different liquids, was measured in the steady condition. The electrical wattage to produce the same steady difference of temperature between the trap vessel and the outer kerosine was determined by a separate experiment. The temperature of the kerosine in the outer vessel was controlled by running ice-cold water around the vessel.

In the experimental arrangement, the energy absorbed in the trap vessel was $I\{1-\exp(-\beta x)\}$, where β, the energy absorption coefficient, was 2α, α being the usual amplitude absorption coefficient. I is the incident intensity in the liquid, and would be the same for all liquids in the trap vessel if we consider that the interface reflexion remains the same in all cases. In cases of very viscous liquids, however, we expect interface reflexion to be large, unlike the case of ordinary organic liquids. In all liquids, however, for the two vessels, I would be the same, and comparative measurements of wattage due to absorption may be made in the two vessels, and hence the value of α/f^2 for the liquid may be estimated. The expected wattage ratios for different values of α/f^2 are shown in Table 1. The experimental mica separations are used for calculations.

The experimental values of the steady temperature differences measured with accurate thermometers and confirmed by several observations, and of the wattages in the two vessels measured by the electrical method, to give the same steady temperature-differences, are given in Table 2.

If we consider that the beam transmitted to xylene, benzene and carbon disulphide through the mica window remains almost the same, the stiffness or viscosity of the liquids being of the same order, and if we consider that α/f^2 in xylene cannot be greater than 75×10^{-17}, the observed experimental value by other methods, we find, by comparison of Tables 1 and 2, α/f^2 for benzene is also not much greater than

Table 1

Xylene	3·0° C.	3·6° C.	2·0	1·6	1·25
Benzene	3·7° C.	—	2·1	—	1·25*
Carbon disulphide	4·2° C.	4·8° C.	3·2	2·5	1·28
Castor oil	7·0° C.	11·2° C.	2·6	2·5	1·04

* Determined with a different set of observations under changed conditions.

75×10^{-17} and that of carbon disulphide not much greater than 115×10^{-17}. This gives the incident wattage on the mica windows as about 32 W. The ratio of wattages in the two vessels agree, within the experimental error of 2 per cent, with the expected values of the ratios for these values of α/f^2. If in the case of carbon disulphide the real α/f^2 was as high as $5{,}000 \times 10^{-17}$, the ratios of wattages in the two vessels would have been 1·024 and the temperature rise in the smaller vessel, from the wattage–temperature graph, would have been 6·3° C. instead of 4·8° C. This is certainly much beyond the probable error of 0·1° C. in measured values of temperature differences. That with a value of α/f^2 of $5{,}000 \times 10^{-17}$ the ratio of wattages in the two vessels should have been 1·024 is beautifully confirmed by experiments on castor oil, where the ratio of wattages in the two vessels agrees with the expected value, within the range of experimental error. The smaller wattages recorded for castor oil are evidently due to a large reflexion from the interface. The experimental results show that the mean absorption coefficients of carbon disulphide and benzene are not much beyond the values for other liquids of the same nature.

The explanation for this discrepancy between the observed mean absorption coefficient and the absorption coefficient determined by other methods may be understood on the basis of variability of velocities and absorption coefficients in the same liquids, as suggested by one of us[1]. This variability would cause the components of a wave pulse to be more and more out of step with distance. No other explanation of this discrepancy in results seems to be feasible.

A New Development in Aids for Sub-normal Vision

The optical aids conventionally used for the improvement of sub-normal vision at near viewing distances (for example, reading) comprise compound, short microscopic systems of varying magnifications, often obtained by placing an additional convex lens over the objective of a Galilean telescopic unit. These microscopic spectacles present a number of disadvantages; thus they have a very restricted field of view (usually less than 30°), they cause changes in spatial perception and, moreover, are heavy, conspicuous, and, in Australia, very costly. Compound systems are employed because of the contention, expressed throughout the literature, that single high-power convex lenses could not provide the necessary field properties.

I have recently succeeded in developing a series of single high-power convex lenses which, with respect to objects placed in their focal planes, are adequately corrected for oblique astigmatism, curvature error, and distortion over a wide field of view (60°–75°).

These lenses can thus be used as simple microscopic spectacle lenses for the improvement of sub-normal vision. They have already given excellent clinical results in a considerable number of cases, which have been reported elsewhere (*Aust. J. Optometry*, July 1954). All the experimental lenses were made by C. J. Tenukest in the Precision Optics Workshop of the School of Applied Physics of the New South Wales University of Technology[1].

Principles of lens design. With spectacle lenses generally, chromatic aberration, spherical aberration and coma are negligible, the latter two because of the small aperture stop formed by the pupil of the eye. The problem is the study of the images formed by the lens on the far-point-sphere of the eye, by pencils passing through a fixed aperture stop effectively located at the eye's centre of rotation (as the eye moves behind the stationary lens). For lenses assumed 'thin', and moderate obliquities (less than 30°), Emsley and Swaine[1] have developed the necessary third-order theory for ordinary 'best-form' spectacle lenses. By combining four of their equations we obtain for the sagittal and tangential image vergencies:

$$L'_s = L + F + \frac{y^2F}{n(n-1)^2}\left[\frac{2n+1}{2}F_2^2 + F_2\left\{(n^2-1)S - \frac{n}{2}(n+2)F\right\} + \frac{n^2}{2}F^2 - n(n-1)FS + \frac{(n-1)^2}{2}S^2\right] \quad (1)$$

$$L'_T = L + F + \frac{y^2F}{n(n-1)^2}\left[\frac{4n+5}{2}F_2^2 + F_2\left\{3(n^2-1)S - \frac{(n+2)^2}{2}F\right\} + \frac{n}{2}(n+2)F^2 - (n-1)(n+2)FS + \frac{(2n+1)(n-1)^2}{2}S^2 + 2F_2L(n^2-1) - n(n^2-1)FL + 2(n-1)(n^2-1)SL\right], \quad (2)$$

where L is object distance (in dioptres), F is total power of lens, F_2 is back surface power of lens, S is distance from lens to eye's centre of rotation (in dioptres), n is refractive index and y is effective lens aperture (obliquity).

For freedom from oblique astigmatism,

$$L'_T - L'_s = 0. \quad (3)$$

For freedom from curvature error,

$$\frac{1}{2}(L'_T + L'_s) = L + F. \quad (4)$$

By making appropriate substitutions, putting the expression inside the brackets equal to zero, and solving for F_2, a series of ellipses are obtained which give the conditions for the 'correction' of either aberration in terms of lens form (F_2) over a range of lens powers (F). Outside the range of the ellipse, the lens form which reduces the aberration to a minimum is found by differentiating the equation expressing the amount of aberration present with respect to F_2.

Emsley[2] has also recently elaborated the third-order theory for 'spectacle distortion' (based on the 'angle condition' instead of the usual 'tangent condition'), for which he gives the following equation:

$$u_1 = u'_2\left(1 - \frac{F}{S}\right) - u'^3_2\,\frac{F}{6S}\left[\frac{(n^2 - 1)}{n^2(n - 1)^2S^2}\left\{(3F^2_2 + F_2(6(n - 1)S - 3nF) + n^2F^2 - 3n(n - 1)FS + 3(n - 1)^2S^2\right\} - 1\right] \qquad (5)$$

For spectacle distortion to be corrected, the quantity in the brackets has to be equated to zero and the equation solved for F_2; again an ellipse is obtained. With respect to the rotating eye, S denotes the dioptric distance from the lens to the eye's centre of rotation, and for the stationary eye the distance from the lens to the eye's pupil.

For a lens used as a simple microscope (magnifying lens) and placed in the spectacle plane, we now have to solve equations (3), (4) and (5) for positive values of F by putting $n = 1{\cdot}5$, $S = 37{\cdot}5$ ($s = 27$ mm.) and $L = -F$.

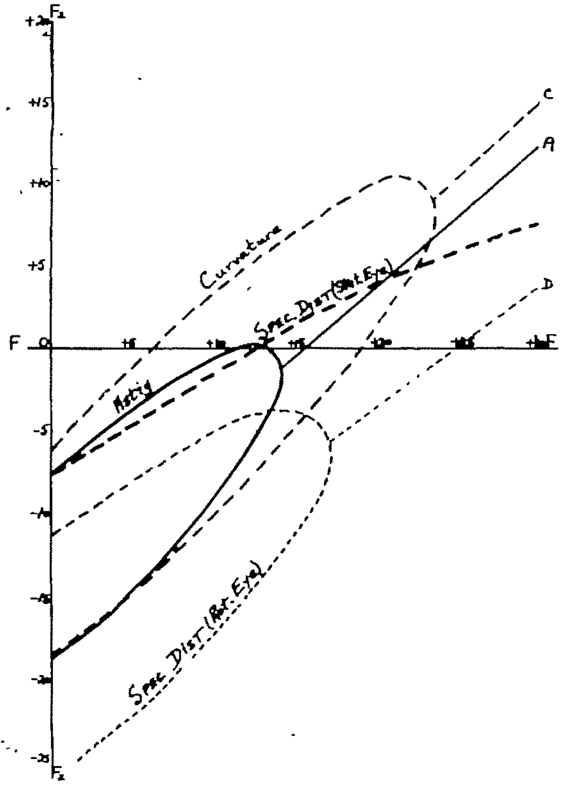

Fig. 1

The semi-ellipses showing the conditions for freedom from each aberration, together with the straight lines giving the conditions of minimum aberration outside the range of the ellipses, are shown in Fig. 1. They are given by the following equations, derived as explained above.

Oblique astigmatism:

$$F_2 = \frac{1}{7}(6F - 93{\cdot}75 \pm \sqrt{1{,}422 + 56F - 11{\cdot}2F^2}) = \frac{48F - 750}{56}\,.$$

Curvature of field:

$$F_2 = \frac{1}{7{\cdot}5}\,(6{\cdot}87F - 93{\cdot}75 \pm \sqrt{2{,}186 + 118F - 9F^2}) = \frac{55F - 750}{60}\,.$$

Spectacle distortion (rotating eye):

$$F_2 = \frac{1}{48}\,(36F - 900 \pm \sqrt{127{,}800 - 432F^2}) = \frac{3}{4}\,F - \frac{900}{48}\,.$$

Spectacle distortion (stationary eye):

$$F_2 = \frac{1}{8}(6F - 240 \pm \sqrt{30{,}704 - 18F^2})\,.$$

Inspection of the graph shows that in several regions the curves intersect or approach each other closely. (Calculation shows that in the region of the curves a change in F_2 of one dioptre will cause oblique astigmatism or curvature error to the extent of approximately $F/50$.)

It is therefore possible to design a series of single high-power convex lenses which, with respect to objects in their focal plane, are adequately corrected for oblique astigmatism, curvature error and spectacle distortion over a considerable field of view, and recognition of this forms the principle of design of the lenses referred to above.

The same principle of intersecting and approaching correction-ellipses can also be successfully applied to the design of 'best-form' spectacle lenses for objects located from infinity ($L = 0$) to a distance of 25 cm. from the eyes ($L = -4$), over a wide range of lens-powers. It is hoped to publish a further communication on this subject at a later date. Finally, consideration is being given at present to the design, along similar lines, of an achromatic doublet eyepiece suitable for various types of optical instruments.

A New Iron Boro-carbide

During a current investigation of the phase relations in the iron–carbon–boron system, X-ray diffraction has revealed the existence of a new boro-carbide which appears to have the structure of the complex cubic carbide reported by Westgren[1] in the chromium–carbon system. He showed that the idealized unit cell contains 92 Cr atoms and 24 C atoms, thus corresponding to the composition $Cr_{23}C_6$; moreover, about 25 per cent of the chromium may be replaced by iron in this carbide. Westgren also reported carbides of similar structure in the iron–molybdenum–carbon and iron–tungsten–carbon systems, in particular in high-speed steels; these carbides, which have been designated 'kappa' by Goldschmidt[2], correspond, at least approximately, to the compositions $Fe_{21}Mo_2C_6$ and $Fe_{21}W_2C_6$. Comparison of the diffraction data for the present boro-carbide with that for the complex cubic chromium carbide as described by Goldschmidt[2] is presented in Table 1. The lattice parameter of the boro-carbide is found to be 10·62 ± 0·02 A.

Specimens were prepared from mixtures of powders (ground to pass a 100-mesh sieve) of an iron–carbon alloy (4·4 per cent carbon) and an iron–boron alloy (5·7 or 8·9 per cent boron) or boron by heating in an evacuated 'Vycor' tube at 850° C. for extended periods. Although various changes in the diffraction patterns were noted during the first few days, further changes were not observed in specimens heated for periods in excess of a week.

† Goldschmidt (ref. 3); interplanar spacings converted to angstroms.
Key to intensities · VS – very strong; S – strong; MS – medium to strong; M – medium; MW – medium to weak; W – weak; VW – very weak.

This new boro-carbide has been found in several of the samples in the range 1½–2½ per cent boron and 2½–4½ per cent carbon. Analogy with the Westgren carbides would suggest a composition corresponding to $Fe_{23}(C,B)_6$. The question as to whether this boro-carbide can exist over a substantial range of compositions is not settled; however, all samples so far observed have the same lattice parameter within the stated error of ± 0·02 A.

If we choose to consider the hypothetical carbide $Fe_{23}C_6$, then it may be said that Westgren and Goldschmidt have produced carbides in which chromium, molybdenum or tungsten has been substituted for iron. To the best of our knowledge the present boro-carbide is the first reported case in which another element (boron) has been substituted for carbon in this structure. This type of carbide has generally been found in, and regarded as characteristic of, some stainless and high-speed steels. It is possible that the appearance of boron therein may eventually shed some light upon the pronounced influence of boron upon the hardening properties of steel.

Effect of Nitrogen Dioxide on the Thermal Decomposition of Ethyl Nitrite

THE value of gas chromatography as a technique for the analysis of the minute quantities of products formed during the kinetic studies of gas reactions is well illustrated by recent work on the gas-phase reaction between ethyl nitrite and nitrogen dioxide. Studies of the behaviour of ethyl nitrite, ethyl nitrate and water on a partition column of kieselguhr wetted with di-butyl-phthalate and eluted with nitrogen revealed that a complete separation of a mixture of the esters and water can be achieved. Using gas chromatography, it has thus been possible to identify three major components, namely, ethyl nitrite, ethyl nitrate, and water, in the residue from the reaction between ethyl nitrite and nitrogen dioxide at about 190° C. Few other micro-analytical techniques would have enabled this to be done so simply or so quickly.

40 mm. of ethyl nitrite and 40 mm. of nitrogen dioxide were allowed to react in a glass vessel of approximately 90 ml. capacity. The temperature of the reaction was about 190° C. Analysis of the residues from interrupted runs for periods up to one hour are given in the table. These show that the quantity of ethyl nitrate produced reaches a maximum after 10 min. and becomes negligible after one hour. The residue of ethyl nitrite was identified on all chromatograms but not quantitatively estimated.

Time of reaction (min.)	2 0	2 8	3 5	5·5	7·5	11·0	15 0	25·0	45 0	60 0
Pressure of ethyl nitrate (mm. mercury)	1·8	2 5	3 9	4 4	5·1	5·3	4·6	3 4	0 9	≃0 0

The formation of ethyl nitrate during the decomposition of ethyl nitrite in the presence of nitrogen dioxide affords direct evidence in favour of the reaction:

$$C_2H_5O + NO_2 \rightarrow C_2H_5O.NO_2, \tag{1}$$

originally suggested by Phillips[1] in explanation of the inhibition of the thermal decomposition of ethyl nitrate by nitrogen dioxide. In this event, it is possible that previous values obtained for the rate of decomposition of ethyl nitrate do not refer to the rate of the reaction:

$$C_2H_5O.NO_2 \rightarrow C_2H_5O + NO_2, \tag{2}$$

since the decomposition involves the equilibrium

$$C_2H_5O.NO_2 \rightleftharpoons C_2H_5O + NO_2. \tag{3}$$

These conclusions would mean that the effect of nitric oxide on the decomposition of ethyl nitrate previously ascribed[2] to the reaction:

$$C_2H_5O.NO_2 + NO \rightarrow C_2H_5O.NO + NO_2, \tag{4}$$

is probably due to the occurrence of

$$C_2H_5O + NO \rightarrow C_2H_5O.NO, \tag{5}$$

proceeding in preference to (1) in the presence of initially added nitric oxide. This would also explain Levy's[3] observation of the production of ethyl nitrite (in quantities greater than 70 mol. per cent) during the normal decomposition of ethyl nitrate.

Acknowledgment is made to Dr. Peter Gray (Cambridge) for recent correspondence on this subject.

Structural Changes during the Fatigue of Copper

RECENT experiments on annealed low-oxygen high-conductivity copper have shown that, under direct fatigue stresses, the structural changes revealed by back-reflexion X-ray photographs (cobalt $K\alpha$ radiation; film-to-specimen distance, 10 cm.) are markedly dependent upon mean cyclical load.

The tests were carried out on a variable-frequency testing machine, which applied alternate tensile and compressive loads to the test specimen. The mean cyclical loads were conveniently varied within restricted limits by placing weights on a counter-balance pan which was attached to the straining device of the machine by a flexible steel cable passing over a pulley.

At frequencies of both 200 c./min. and 400 c./min., small variations in the value of the counterweight attached to the straining device were found to produce disproportionate changes in the X-ray diffraction patterns of test-specimens after 1,000 stress cycles at about ± 5 tons/sq. in. At the same time, permanent dimensional changes were similarly influenced by variations in the magnitude of the counterweight, as will be seen from Table 1.

Table 1. PERMANENT STRAINS AFTER 1,000 CYCLES AT ± 5 TONS/SQ. IN APPROXIMATELY

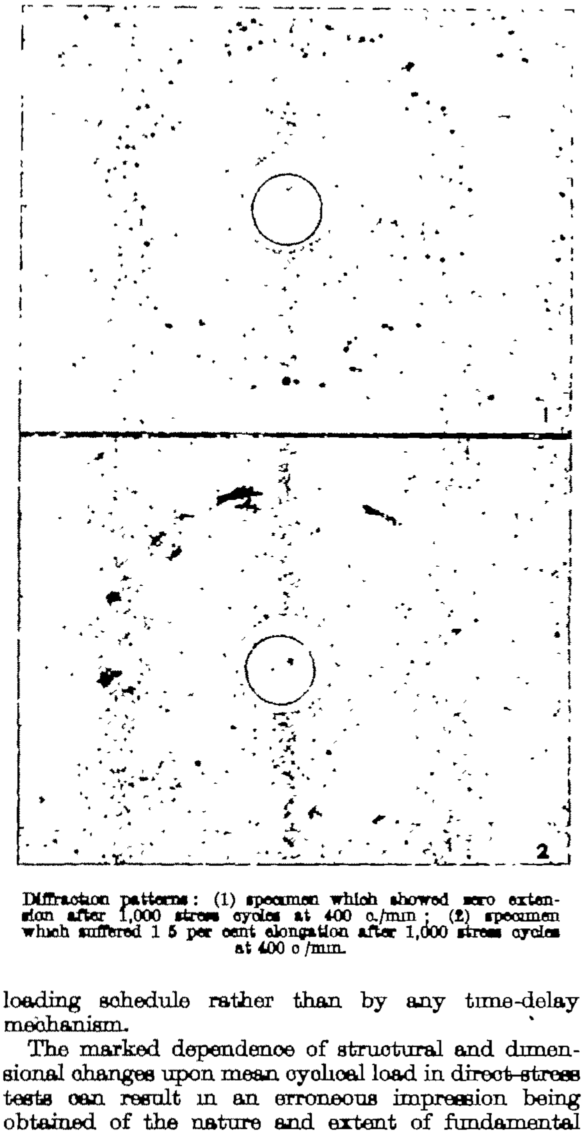
200 c./min. tests		400 c./min. tests	
Counterweight (lb.)	Permanent strain (per cent)	Counterweight (lb.)	Permanent strain (per cent)
40	− 1	40	− 1
60	− 0·8	80	Nil
80	+ 1	120	+ 1·5

In those cases where the permanent dimensional changes were slight or negligible, the X-ray patterns showed relatively small changes except for a general diffusion of the sharp diffraction spots typical of the annealed material (see Fig. 1). However, the changes in the patterns were quite pronounced in all cases where the permanent dimensional changes exceeded about ± 1 per cent, at both high and low frequencies (see Fig. 2).

Wood and Head[2], in their direct reversed-stress tests on oxygen-free high-conductivity copper, attributed their observations of pronounced diffusion and circumferential arcing of X-ray diffraction spots at 'sub-critical' testing frequencies (< 350 c./min. approximately) and the relative absence of changes at higher frequencies to the influence of a delay period, representing the finite time between application of a stress and development of the corresponding plastic strain. These tests were done on the machine used in the present work.

However, repeated tension experiments which I have carried out on similar material have shown that the use of the higher testing frequencies fails to inhibit structural changes (as revealed by X-ray diffraction) and dimensional changes, at least after 100 cycles.

Other work[3] has shown that, even under static loading conditions, annealed copper can withstand reversed stresses of ± 5 tons/sq. in. with only slight changes in X-ray diffraction patterns, providing a suitable 'stepped' loading sequence is followed. It is clear that, in this latter case, structural changes are minimized by the choice of an appropriate preliminary loading schedule rather than by any time-delay mechanism.



Diffraction patterns: (1) specimen which showed zero extension after 1,000 stress cycles at 400 c./min.; (2) specimen which suffered 1·5 per cent elongation after 1,000 stress cycles at 400 c./min.

The marked dependence of structural and dimensional changes upon mean cyclical load in direct-stress tests can result in an erroneous impression being obtained of the nature and extent of fundamental structural changes under fatigue stresses, unless load-balancing operations of high precision are practised. In the absence of confirmatory evidence from low- and high-frequency tests carried out in other types of machines (for example, rotating bending tests), it seems possible that the critical-frequency effect reported by Wood and Head[2] may have been attributable primarily to progressive dimensional changes arising from characteristics of the testing machine.

Some preliminary rotating bending tests have, in fact, been carried out, and X-ray diffraction studies have indicated that the structural changes, even at 21 c./min., may be relatively slight.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Experimental Officer to work in the Department of Entomology on Aphid Ecology—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting 104 (November 25).

Senior Technician to take charge of the workshop in the Department of Physics—The Registrar, University College of North Wales, Bangor (November 29).

Demonstrator or Lecturer in Pathology—The Registrar, The University, Leeds 2 (November 30).

Lecturer (with an honours degree in engineering and some professional experience) in Mechanical Engineering—The Registrar, King's College, Newcastle-upon-Tyne (November 30).

Senior Lecturer, Lecturer and Assistant Lecturer in the Department of Electrical Engineering—The Registrar, The University, Manchester 13 (November 30).

Assistant Agricultural Economist (graduate in economics and/or agriculture)—The Registrar, The University, Bristol 8 (December 1).

Technician or Radiographer (preferably with qualifications in science, mathematics or radiography) required for therapeutic and tracer measurements with radioactive isotopes—The Secretary, Board of Governors, Hammersmith Hospital and Postgraduate Medical School, Du Cane Road, London, W.12 (December 1).

Assistant Lecturers (2) in Botany—The Registrar, The University, Manchester 13 (December 4).

Head (with a good honours degree, teaching and industrial experience, and preferably with research experience) of the Engineering Department—The Principal, Kingston Technical College, Fassett Road, Kingston-upon-Thames (December 4).

Physiologists, Pharmacologists or Zoologists (with a first- or second-class honours degree, or equivalent qualification) at a Ministry of Supply Experimental Establishment, near Salisbury, Wilts—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting G386/54A (December 4).

University Demonstrator in Physical Chemistry—Dr. F. B. Kipping, Chemical Laboratory, University of Cambridge, Cambridge (December 4).

Scientific Officer (British nationality, with an honours degree in chemistry and postgraduate experience in agricultural chemistry, or an honours degree in agricultural chemistry) in the Chemical Research Division of the Ministry of Agriculture, Government of Northern Ireland—The Secretary, Civil Service Commission, Stormont, Belfast (December 6).

Chair of Glass Technology—The Registrar, The University, Sheffield 10 (December 11).

Mathematicians or Physicists (with a first- or second-class honours degree in mathematics or physics and preferably with experience of analyses of statistics and preparation of appreciations of trials data) at a Ministry of Supply Experimental Research Establishment, near Salisbury, Wilts, for operational research—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A 316/54A (December 11).

Senior Scientific Officers (with a first- or second-class honours degree or equivalent in physics or electrical engineering, and at least three years postgraduate research experience), at the Royal Aircraft Establishment, Farnborough, Hants, to work on research in and development of radio and other fusing techniques for guided weapons and bombs—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.320/54A (December 11).

Assistant Keeper (with a first- or second-class honours degree in electrical engineering or equivalent qualifications, and preferably a knowledge of at least one modern foreign language) in the Department of Electrical Engineering and Communications, Science Museum (Ministry of Education)—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S.270/54 (December 14).

Chair of Chemistry tenable at King's College—The Academic Registrar, University of London, Senate House, London, W.C.1 (December 14).

Curator (with an honours degree in zoology) of the Aquarium—The Secretary, Zoological Society of London, Regent's Park, London, N.W.1 (December 15).

Lecturer or Senior Lecturer (adequately qualified in chemistry with specialization in the field of physical chemistry) in Physical Chemistry, at the University of Tasmania and Hobart Technical College—The Agent-General for Tasmania, 457 Strand, London, W.C.2, or the Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 21).

ASSISTANT DIRECTOR (well grounded in high polymer and physical chemistry, and able to appreciate the impact of fundamental work in these and allied fields on the practical development of plastics, particularly from indigenous resources) OF THE DIVISION OF PLASTICS AND HIGH POLYMERS—The Secretary, Council of Scientific and Industrial Research, Old Mill Road, New Delhi, India (December 31).

BIOMETRICIAN for duties which include the design of experiments in all phases of tobacco production, together with the analysis of data and related statistical practice—The Director, Tobacco Research Board of Southern Rhodesia, P.O. Box 1909, Salisbury, Southern Rhodesia (December 31).

LECTURER IN FLUID MECHANICS in the Department of Aeronautics and Fluid Mechanics—The Secretary of University Court, The University, Glasgow (January 8)

LECTURER IN THEORETICAL PHYSICS—The Registrar, The University, Reading (January 17).

ASSISTANT LECTURER IN APPLIED MATHEMATICS—The Registrar, The University, Nottingham

BACTERIOLOGIST for work primarily concerned with the production and testing of bacterial vaccines and toxins—Head of the Biological Division, The Wellcome Research Laboratories, Beckenham, Kent.

GRASSLAND AGRONOMIST, a GRASS BREEDER, and a CEREAL BREEDER (with a good honours degree in botany or agricultural botany), and ASSISTANTS to a CYTOLOGIST and GRASS BREEDER (with a pass degree in botany or agricultural botany), at the Welsh Plant Breeding Station, Aberystwyth—The Registrar, University College of Wales, Aberystwyth.

PHYSICIST (with an appropriate science degree and preferably with a knowledge of electronics), to assist in problems related to the treatment of cancer—The Medical Superintendent, Western General Hospital, Edinburgh 4.

PHYSICISTS (4) (with a good honours degree and some research experience) to undertake research on (*a*) shrinkage and dimensional stability of fabrics (Ref. P.1), (*b*) creasing and crease-recovery of fabrics (Ref. P.2), (*c*) the fatigue of textile fibres (Ref. P.3), and (*d*) fibre assemblies (Ref. P.4)—The Secretary, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester.

RADIO CHEMIST, Principal Scientific Officer or Senior Scientific Officer grade (with a first- or second-class honours degree in chemistry, and at least three years postgraduate research experience), to work in a team engaged on fundamental research work on radioactive materials—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 154/WGH/2.

RESEARCH ASSISTANT (honours graduate, preferably with research experience) IN ORGANIC CHEMISTRY—The Secretary, University College, Exeter.

SENIOR SCIENTIFIC OFFICER or SCIENTIFIC OFFICER (with a first- or second-class honours degree in physics) to carry out research into the measurement of radiation with emphasis on the high intensity and high-energy regions—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 81/WGH/2.

THE BRITISH CIVIL SERVICE

THE centenary of the Trevelyan–Northcote report on the organization of the permanent Civil Service in Great Britain has prompted *The Political Quarterly* to devote almost the whole of its current issue to a discussion of the Civil Service in relation to its contemporary tasks and the needs of the British people. The major grounds of current criticism of the Civil Service are fairly and concisely recapitulated; but the excess of criticism and its frequent extravagances are repudiated as firmly as they are by Mr. Herbert Morrison in his recent book and by Prof. K. C. Wheare in his commemorative lecture. The implications of the Crichel Down episode are carefully weighed, but the general verdict remains that the British Civil Service continues to be the best in the world.

Most of the articles contributed to this number pay some attention to the problems with which the scientist is most closely concerned; for example, to the position and recruitment of the professional and scientific classes of the Civil Service, and the way in which expert advice should be given to the Government. Where such problems are not specifically mentioned, as in Sir John Woods's excellent article on Treasury control, the principles which guide current practice are clearly expounded. This article brings out, for example, some of the difficulties which are involved from the national point of view in the extension of the principle of quinquennial or block grants. Against the undoubted advantages from the point of view of planning research or educational policies, for example, which such a practice confers, there are certain drawbacks, which Sir John indicates. Simple or conclusive answers to such questions are rarely to be found, and this article is a valuable contribution to the understanding and goodwill on both sides on which effective public control of expenditure and the efficient use of resources—in money, materials or man-power—ultimately depend.

The essay of least interest to the man of science is that dealing with the Foreign and Commonwealth Services. It contains, apart from Prof. W. A. Robson's article, "Recent Trends in Public Administration", the only reference to the Colonial Service made in the symposium; but this brief reference ignores entirely the problems of the Colonial Scientific Service and the implications both of political developments in the Colonies and of technical assistance and the Colombo Plan for that service. The bearing of Colonial Welfare and Development Acts and the large amount of research now being conducted by or on behalf of the Colonies are nowhere considered.

Of the more general articles, one by Mr. C. R. Attlee deals with the relations of Civil servants, Ministers, Parliament and the public much on the lines of Mr. Morrison's book, and comments on the advantage to the country of recruiting more scientists in the higher ranks of the Civil Service—and also the difficulty of doing so. It may be noted here that in considering recruitment, Mr. L. N. Helsby, First Civil Service Commissioner, expresses the view that over the past nine years the Service has probably attracted at least a fair share of all scientific talent short of the highest class and also, recently, a reasonable share of recruits of exceptional ability. In spite of a serious shortage of engineers and surveyors, he does not believe that the Civil Service is seriously understaffed in comparison with the professions as a whole.

Mr. Helsby does not suggest that the final answers can yet be given to the question whether in the scientific and professional field the Civil Service is getting enough recruits and of the right kind; his present answers are conditioned by the fact that leading industrial firms themselves find difficulty in filling all their posts with exactly the type of person they desire. He maintains that the use made by the Civil Service Commission over the past nine years of the interview method in recruiting scientists has been developed sufficiently to secure the advantages of central recruitment and to meet the special circumstances of government scientific work. He does not, however, really touch on the recruitment to the administrative class, and especially at the highest levels, of scientists and technologists who show themselves possessed of the requisite administrative ability.

That problem, and also the further problem of the status and function of the specialist officer, are faced by Mr. H. R. C. Greaves. Reviewing the structure of the Civil Service, Mr. Greaves notes that, in spite of their present weakness as a group within the hierarchy, the considerable growth in numbers and significance of the professional and scientific officers in the Service, which has placed them near the sources of administrative decision and in close contact with the highest administrators, has given them opportunities of attaining such positions, which some at least have been able to seize. Mr. Greaves is not complaisant. He admits that a widening of the social basis of recruitment to the administrative class might also assist in the recruitment of those whose university training had been in science and not solely in the arts. He points out that the growth of attention to post-entry training and the recognition of Treasury responsibility in this matter give promise of the reduction of hierarchical rigidities, and one of his suggestions for improving the structure of the Civil Service and the correction of departmentalism is a more elastic, less rigid treatment of the hierarchical principle in recruitment, taking advantage particularly of the existence of the specialist or professional groups and of the newer administrators in nationalized services. With this, he suggests that much more could be done in training, in conjunction with the universities, by bringing together young officers from the Civil and other public services, and by the promotion of individuals who have distinguished themselves by creative research and training, to create a cadre of first-rate officers suited for all branches of public service. Thirdly, he suggests a lively and elastic promotion policy conducted by a body of officials, specially trained in the art of selection, ranging wide over all public employees, and concerned only to choose well to the public advantage, regardless of vested interest or departmental prejudice.

Mr. Greaves believes that for such measures to succeed it would be necessary to form a small 'machinery of government department', under the head of the Service and attached to the Prime Minister, which would provide a highly trained and carefully selected general staff for all branches of the Civil and public services. He argues that the experience and knowledge required can only be provided by a greatly strengthened body of officials, coupled with a clearer assertion of the powers of the head of the Service and a more definite assumption of authority by the Prime Minister. The suggestion is somewhat controversial, though Mr. Greaves claims support for it in an answer of Sir Warren Fisher to the Select Committee on National Expenditure in 1942, and it is not in conflict with Sir John Woods's remarks on Treasury control.

Sir John Woods is not concerned that the Treasury should be over-powerful; but he points out that the real question is the way in which control is exercised. Very little direct light is thrown on that question in this symposium. Sir Edward Bridges, viewing the reforms of 1854 in retrospect, tempers his conclusion that those reforms have stood the test of time with some observations on the qualities needed in the Civil servant which bear on this issue. He directs attention to the consequences of the infinitely wider range of duties with which the Civil Service to-day is charged, and the change in its composition compared with that of 1854. It now comprises, for example, very large scientific, professional and technical staffs, many of whom enter the Service after professional experience outside. Many problems are involved in ensuring that the relationships of these professional staffs with their colleagues in the other branches of the Service are on the best possible lines.

Such questions, Sir Edward remarks, are outside the scope of the report of 1854. It might be added that they are not entirely a matter for the Civil Service, and it is at least possible that professional bodies representing the whole of a profession, and not simply that part of the profession employed in the Civil Service, could give valuable assistance in working out solutions. That may be considered a special aspect of a second change which Sir Edward notes and which, so far as concerns the administrative, executive and clerical grades, he regards as the most significant. This is the increasing extent to which Civil servants are brought into contact with the public, through the larger concern of the State in economic affairs and industry, and through the work of the social service departments. Far more than before, the Civil servant is called upon to meet and to deal on behalf of the Minister with members of the public, either as individual citizens seeking information or redress about their benefits under social security, or with industrialists.

This calls for a wider range of qualities from the Civil servant and, because his task is changing and perhaps becoming rather more difficult than before

Sir Edward remarks that even greater care must be taken in his recruitment and training. That suggestion is endorsed in the editorial notes and comments which introduce the whole symposium; incidentally these notes put the symposium in admirable perspective, both by a brief recapitulation of current criticism and by the bibliographical footnotes which include most of the serious contributions to the discussion over the past decade or more. Training is, in fact, regarded as still the weakest part of the Civil Service, in spite of improvements since 1946, and specifically the Crichel Down episode is regarded as representing a failure of training. *The Political Quarterly* believes that Civil servants would not behave thus if they received adequate training and insight in the proper manner of treating individual citizens at an early stage in their career.

The proliferation of organs and the complexity of the machinery is regarded as a contributory factor and adds substance to criticism which has fairly been made of the Government's decision to abolish the Ministry of Food and to transfer its residual functions to a Department the internal organization of which is already complex and of dubious efficiency, and which is not entirely met by the appointment of an independent committee to review the regional and local organization of the two Ministries.

One of the merits of *The Political Quarterly* symposium is that it turns attention to the more vital problems of a modern bureaucracy, and particularly to the need for an approach from outside as well as from within the Civil Service. Two major suggestions are made in this connexion. One is that the Treasury should appoint an advisory council on the Civil Service, consisting of leading Civil servants, business men, industrialists, university teachers of politics or public administration, and others with experience of public life. The council would have the function of advising the government on general or particular matters requiring investigation or consideration concerning not only the well-being of the Service, but also its improved relations with the public and the greater efficiency of its work. The second suggestion is that the government should publish an annual report on the Civil Service. At the least, such a report might forestall the captious criticism which continually arises whenever the quarterly statistics regarding the Civil Service are published. After all is said, the fact remains that the size of the Civil Service is determined by the duties which it is required by Parliament to perform; hence it depends on the administrative implications of national policy, and only to a very minor degree on the efficiency with which the Service carries out that policy.

These suggestions are designed to focus attention, both within and without the Civil Service, on the primary questions of the proper relations between the governed and the governors, and the procedures, attitudes and ethics which should pervade public administration—and at the local government level as well as at the centre. Without due attention to these primary questions, the right answers and the right emphasis are unlikely to be found when we consider the secondary questions of recruitment, salary scales, working conditions, mobility, flexibility and the position of scientific and professional staff. It is not suggested, indeed, that such questions are unimportant; but a clear conception of the functions of the Civil Service in the modern State and of the functions and responsibilities of the scientific expert must guide decisions as to the best means by which such functions are to be discharged and the character of the organization provided for the purpose.

There are several suggestions made to this end. The idea of a Civil Service training college finds firm support as a means of countering departmentalism, in spite of the increase in staff that it would involve. A deliberate policy of interchange between departments, and between departments and nationalized industries, is advocated, instead of mobility being left to chance, as at present. Sir Edward Bridges notes that to-day, of thirty-three 'permanent secretaries' of major departments, sixteen started their official career in other departments, and four others have spent long periods in other departments; but it is not clear how much advantage is being taken of the new opportunities to avoid compartmentalism.

The symposium appears to suggest that the present system of vesting the ultimate control of the Civil Service in an administrative class drawn mainly from the universities is right; the wider basis of recruitment to the universities is securing a reasonable representation of social classes even though full equality of opportunity has not yet been achieved. The real deficiencies are in what is done in the matter of training; nor can confident answers yet be given to such questions as whether we can make the Civil Service more flexible and reduce rigidity of promotion, grading and salaries so as to permit the encouragement of real merit; though something is being done in the Scientific Civil Service (see p. 999 of this issue). Nor can it yet be said that a system of interchange can be worked out with the universities or with the nationalized industries in spite of the advantages of interchange demonstrated by war-time conditions.

The scientist will note that his own special difficulties and problems are fully appreciated, though there is not in the symposium any adequate treatment of the central problems of the limits of expert knowledge and the presentation and consideration of such advice in the task of government which Mr. D. K. Price's recent book illuminated in the American context. Nothing in the contributions to *The Political Quarterly* suggests that we have really worked out the right role of professional staffs in the Civil Service—medical, scientific or engineering—or that we can assume, without further inquiry, that the very great resources which the government is putting into scientific research and development are being efficiently operated. Even if the Civil Service is attracting a fair share of young scientists of the highest ability, it does not follow that they or their colleagues in government service are not being used for duties which could be performed equally well by others less highly trained.

On these and allied questions the symposium is a challenge to realistic and constructive thinking, both by individual scientists and by their professional organizations. Prof. W. A. Robson's article in particular should be noted by them, with its recognition of the much larger place which science now occupies in the sphere of government, and its strong support for administrative training and responsibility for the professional and scientific classes, and for the deliberate extension of their relevant experience so as to increase their usefulness. If, however, within the next few years satisfactory solutions are not found for the problems of how best to present and utilize scientific and other expert advice in the work of government at all levels, to guide policy and decisions and to secure the efficient utilization of scientific and technical man-power within the Civil Service, some large share of responsibility must clearly rest on scientists themselves for failure to grasp the opportunities now before them.

FOOD PRODUCTION AND POPULATION

World Population and World Food Supplies

By Sir E. John Russell. Pp. 514 + 44 plates. (London: George Allen and Unwin, Ltd., 1954.) 50s. net.

THIS book, with its wealth of information on the present position and possibility of development of agriculture in the different countries of the world, is a valuable addition to the growing literature on the question of whether the population will grow to a size that the earth will not be able to support.

The main cause of the present 'explosion' of population is, of course, the application of modern preventive medicine in reducing disease in countries with a high death-rate. In the limited areas where it has been applied, the population is increasing at a rate which will double it in less than thirty years. In recent years, with the help of the World Health Organization and other agencies, practically all countries are now beginning to apply modern hygiene. Hence, estimates of the size of population in the future have had to be revised upwards. In 1946 it was estimated that the population of about two thousand million before the Second World War might reach four thousand million by the end of the present century. The latest estimate is that it may reach that figure by 1980 and, if the present accelerating rate of growth continues, between five and six thousand million within the subsequent fifty years.

It is obvious that the only solution of the population problem is the reduction of the reproduction-rate to the level of the replacement-rate. There is commendable propaganda for birth control to attain that end; but owing to religious opposition, and the fact that many countries are taking measures to maintain or increase the birth-rate, it is doubtful whether the propaganda will have much immediate effect. Some take a gloomy view of the future. The present rather sudden rate of increase of population is, however, not a new phenomenon. It occurred in Western Europe in the eighteenth century, when the population of England and Wales, for example, rose from about ten to thirty-three million in spite of large-scale emigration. It is estimated that between 1800 and 1924 about sixty million people left Europe. Early in the present century, Western Europe passed through this phase of rapid expansion of population, and the birth-rate is now so low that the Western German Minister of Home Affairs recently pointed out that, unless voluntary birth control can be reduced, the European race is on the decline. It is probable that, when the countries at present in the expanding phase of population reach the standard of living and education of Western Europe, the birth-rate will fall and world population will become stable or perhaps even decline. This, however, is by no means certain. In the United States there has been a rise in the birth-rate, and the percentage rate of increase now rivals that of India.

It is impossible to predict with any degree of certainty the size to which world population may grow. The compulsory checks are war, disease and famine. If the attempts to eliminate the first two be successful, then, apart from voluntary birth control, which may take a long time to be effective, there remains only famine. This raises the vitally important question of whether population growth will outrun the capacity of the earth to produce food. On this there are two views, both of which warrant serious consideration.

One, put forward by Vogt, is that owing to soil erosion, which has destroyed about half the original fertile land on the earth and is still continuing, the only way to avoid famine is by birth control, compulsory if necessary, and the stopping of the elimination of disease in over-populated countries until the population is reduced to what the country can support. The other view, like that of Rosin and Eastman, is that with modern technology there is practically no limit to the amount of food that can be produced.

The information given in this book supports the latter view, at least to the extent of showing that a great increase of food production is possible. For example, in India, which is usually quoted as the outstanding case of an over-populated food-deficit country, the use of fertilizers in proper amounts would increase the yield of different crops by 30–100 per cent. The cultivation of rice by the Japanese method, using fertilizers, increases the yield more than 100 per cent. Then there are more than a hundred million acres of fertile land overrun by weeds and jungle which could be cleared by bulldozers. Shortage of water is a limiting factor in agriculture, but less than 10 per cent of the water in the rivers is used for irrigation. With pumps for small areas and multi-purpose dams like the Damodar Valley project, to convert the destructive force of floods to electricity and provide water for irrigating, vast areas could be brought into cultivation.

The physical possibilities for increased production in India are very much the same for all food-deficit countries. If the land at present under cultivation, or which could easily be put under cultivation, were made to yield to its maximum, the food supply of these countries could be doubled. Soil erosion could be stopped and the ruined land reconditioned. But technology cannot be applied to bring about the rapid increase of food supplies in the food-deficit countries owing to the lack of the necessary fertilizers, agricultural equipment and other industrial products. Where these are available, together with the incentive of a guaranteed market, food production can be rapidly increased, as occurred during and after the Second World War in Britain, when production was increased about 30 per cent, and in the United States, where surpluses have piled up to the value of 6,229 million dollars by March of this year. In the food-deficit countries the main obstacle is the lack of the necessary industrial products which they are too poor to purchase. The average income in these countries is only about £20 per head—less than a tenth of what it is in Western European countries. Though the Food and Agriculture Organization, the American and the United Nations Technical Assistance Scheme, and the British Colombo Plan are doing excellent work with their limited funds, progress is too slow. Up to 1951 world population had increased by 12 per cent since the Second World War, while food supplies had increased by only 9 per cent. Owing to three good harvests, the supply per head is now about equal to what it was in 1938, but the greater part of the increase is in the already well-fed countries. In the Far East, even if targets for 1956–57 are reached, production per head will still be about 10 per cent below the 1938 level when 80 per cent of the population suffered from malnutrition and periodic hunger. It is estimated that the long-term investment of about £4,000 million a year—that is, about 10 per cent of what the world is spending on armaments—would be needed to put an end to hunger and poverty within a reasonable time.

With modern engineering and agricultural technology, to the latter of which the author of this book has made a notable contribution, it is now possible to provide sufficient food for all mankind, even though the population should grow to twice its present size. The main difficulty is the adjustment of the economic and political structure of the world to the new age of abundance which science has made possible.

BOYD-ORR

A TREATISE OF GENETICS

Traité de Génétique

Par Prof. Ph. L'Héritier. Tome 1: le Mécanisme de l'Hérédité Génétique Formelle. Pp. iv+344. 1500 francs. Tome 2: la Génétique des Populations. Pp. iv+345–518. 900 francs. (Collection "Euclide": Introduction aux Études scientifiques. Biologie Animale—Section dirigée par Maurice Caullery.) (Paris: Presses Universitaires de France, 1954.)

THERE is an unquestionable demand for an elementary treatise of genetics. One written by Ph. L'Héritier, who has contributed brilliantly and decisively to two fields of genetics, cannot fail to arouse expectations. The two published parts of this treatise, however, though thoughtful and informative, are somewhat disappointing in three respects. First, they lack balance between the various parts of the subject. Second, they wander repeatedly from a logical sequence in the main argument. Third, they ignore the difficulties and evolution of basic ideas such as gene, allele, etc.

For example, in Vol. 1 (the mechanism of formal genetic inheritance) a whole chapter out of a total of six deals with interspecific hybridization, a subject which has limited relevance to formal genetics. The formal genetics of *Drosophila* is given a share far in excess of the very large one which everybody will agree it deserves. In contrast the formal genetics of man, of *Neurospora*, of *Aspergillus*, of cotton, etc., with their distinct contributions to our ideas of mutation, segregation, organization of genes, etc., are barely mentioned, if at all. In Vol. 2 (genetics of populations) the treatment is prevalently theoretical, with little reference to the vast amount of experimental work on populations either in Nature or in the laboratory. This is the more regrettable in view of the distinctive contribution which L'Héritier himself has made to this field.

An example of disconcerting sequence in the logical development of the subject is that multiple allelism and 'pseudo' allelism are dealt with before linkage and crossing-over. An example of avoidance of the terminological and semantic difficulties is the following definition: ". . . the mendelian character is represented in the hereditary make-up by a discrete particle, called the gene . . ." (p. 21).

On the credit side of this treatise there is the very elementary but clear and adequate treatment of the mathematical theory of population genetics, possibly the most extensive treatment of the subject so far still comprehensible to the non-mathematician. In the first volume, linkage and mapping of the chromosome are treated in a very satisfactory and intelligible way at the elementary level. The last chapter, on the mechanism of mutation, again gives an excellent bird's-eye view of a field which is at present rather fluid.

On the whole, it seems to the reviewer that this treatise, though useful as a reference book for people who are already well versed in the field, will not be equally useful for those who want to acquire a general balanced view of the concepts, the methods and the implications of genetics.

G. PONTECORVO

PLEISTOCENE GEOLOGY AND ARCHÆOLOGY OF NORTHERN FRANCE

Les Limons Quaternaires du Bassin de La Seine

Stratigraphie et Archéologie Paléolithique. (Archives de l'Institut de Paléontologie Humaine: Mémoire 26.) Par François Bordes. Pp. ii+472. (Paris: Masson et Cie, 1954.) n.p.

THIS magnificent volume of the Archives de l'Institut de Paléontologie Humaine is of first-rate importance to all students interested in the Pleistocene geology of northern France and the succession of early Palæolithic industries in the region. In conjunction with Commont's work in the Amiens district and the volume by Georges Dubois on the Pleistocene of northern France which was published by the Société Géologique du Nord in 1924, it gives a picture of the late geological succession in the north-eastern part of the country.

The importance of F. Bordes's new work is not so much in his conclusions but in the fact that he gives such a very large number of sections in gravel and loess pits along the River Seine from Paris to the sea and some others from neighbouring districts. Sections in the Amiens district are given to allow correlation with the work of Commont in the Somme valley. Each section has been carefully studied, and any finds, faunal or archæological, are recorded. Pages of illustrations of implements found are given. The conclusions arrived at, though clearly given, are subservient to the evidence upon which they are based. Whatever may be the final verdict on the Pleistocene successions in the valleys of the Seine and Somme and the correlation of the archæological and geological records, the facts recorded in this volume will have to be taken into account and will provide the basis for the resultant conclusions.

After a first part dealing with methods of study, the sections in a number of pits in the Paris region are considered, and afterwards the Mantes–Vernon area is dealt with in some detail. There follow accounts of sections and finds in the regions of Evreux–Nogent-le-Roi, Gisors–Fleury-sur-Andelle, Elbeuf, Rouen–Neufchâtel, Pont-Audemer and Duclair–Fécamp–Le Havre. For purposes of comparison there follow studies of sections in the Amiens, Beauvais–Clermont and Meaux–La Ferté-sous-Jouarre areas. Then comes the third part of the book, namely, several chapters dealing with the loesses of the region. M. Bordes divides the younger loess into three levels and the older loess into two. He considers the mode of deposition of the material, the fauna contained and the climate under which it was laid down. He studies the evolution of the human industries and their correlation with the loess levels, and ends with three short pages of general conclusions.

An excellent bibliography and list of the sites investigated, together with a map of the district covered, conclude the volume. Altogether, this is a first-class work, full of facts both from the geological and archæological angles, and all students of the subject will welcome it. M. C. BURKITT

ELECTRICAL MACHINES AND TRANSFORMERS

Electro-Magnetic Machines

By Prof. R. Langlois-Berthelot. Translated and revised in collaboration with Lieut.-Colonel H. M. Clarke. Pp. 535. (London: Macdonald and Co. (Publishers), Ltd., 1953.) 65s. net.

WHEN one reads the first sixty pages of this book, one gets the impression that it was written for youths, say, of fifth-form standard. But on reading further one soon realizes that the author's aim is more ambitious, and it appears that a sound knowledge of at least the elements of calculus and vector analysis is required for the full understanding of the book. But those who are not interested in the mathematical treatment of the subject will also find the book attractive, inspiring and thought-provoking. At a time when so much is spoken and written about the necessity of providing in Britain more opportunities for the education of technologists, the few pages in the last chapter on the relation between scientific and technical points of view and on the field of industrial research should appeal to many readers. Technological aspects are given prominence throughout. A special feature of the book is that the general principles and rules are outlined in a straightforward manner and that afterwards various complications to be met with in applying the rules are stated.

The book is written in that clear, logical style to be expected from a French author, and a word of praise should also be said about the competent translation. Much information is contained which is not to be found collected together elsewhere. In this connexion, mention should particularly be made of the chapters on insulation and on ventilation, as well as the section concerning standardization of dielectric test requirements and the concise treatment of transient conditions.

Numerical examples scattered all over the book will prove helpful to the student and designer, and occasional hints for practical exercises to be performed by students will be welcome to the teacher; although he will miss, perhaps, specific problems usually to be found in British and American textbooks of this kind.

The six main parts of the book deal with the following: the family of electrical machines; general anatomy and physiology of electrical machines; the machine from the designer's point of view; the machine from the user's point of view; abnormal conditions of operation; and miscellaneous general comments, including a general introduction to technique of electrical machines. Some appendixes deal with the notations and symbols used, with simple relations like sinusoidal functions, complex quantities and polyphase systems, and with a brief introduction to circle diagrams and the like.

While the book deals in a general way with transformers, synchronous and asynchronous alternating-current machines, single- and three-phase collector machines and direct-current machines, further volumes are apparently planned by the author, a second one being already in preparation dealing in greater detail with transformers and alternators.

A few critical remarks may be permitted. It is somewhat astonishing that under the heading "Various Special Machines" no mention is made of the direct-current cross-field machines invented just fifty years ago by E. Rosenberg. They have been extensively used for lighting railway trains, the feeding of searchlights and for arc-welding purposes not only in Germany and Austria but also in France, where before the First World War quite a number of trains of the P.L.M. Railway were equipped with them; and also their further development connected with the name of Pestarini might have been mentioned, as the 'metadynes', 'amplidynes', 'rototrols' and 'magnicons' are now frequently used in regulating technique—for example, as auxiliaries for the excitation of large and small alternators or of the generators of Ward-Leonard sets.

In a book of this size, perhaps more emphasis could have been laid on the importance of a good power factor in induction motors. True, the power factor is mentioned in several places, particularly also in the appendix. But in the part dealing with the machine from the user's point of view a warning might have been expressed against installing outsize induction motors in industrial plant, since this happens frequently in practice; as the power factor declines markedly at partial loads, an undesirable inductive load must be carried by the supply mains in these cases.

Very few misprints have been noticed, but one must be mentioned. In the explanation of the positive and negative phase-sequence on p. 447, the compositor apparently omitted half a sentence. But all these are minor blemishes, and the book can be strongly recommended and is a very welcome addition to the literature of electrical machines, in spite of the fact that this is already rather extensive. Author, translators and publishers can be congratulated upon this production. R. NEUMANN

Les applications de la mécanique ondulatoire à l'étude de la structure des molécules

Réunions d'études et de mises au point, tenues sous la présidence de Louis de Broglie. Pp. 224+2 plates. (Paris : Éditions de la Revue d'Optique théorique et instrumentale, 1953.) 1600 francs.

THIS volume contains the text of the eleven lectures and introductory address delivered at the eighth in the series of annual conferences on physical topics which have been held since 1944 under the general presidency of Prof. Louis de Broglie. Applications of wave-mechanics to the study of the structure of molecules was the topic chosen for the 1951 conference, and the lectures were delivered on various dates during April–June of that year. Both experimental and theoretical applications are featured. J. Lecomte gives an interesting and informative review of progress in the technique of infra-red spectrometry during 1940–50, and J. Wyart discusses the determination of interatomic distances by X-ray and electron diffraction, while O. Chalvet and C. Vroelant deal briefly with the theoretical calculation of interatomic distances.

On the more chemical side there is an excellent description by P. Ramart-Lucas of the influence of the steric effect on the electronic structure of carbon and nitrogen, and this is supplemented by a discussion by C. Sandorfy of the theories of the electronic spectra of organic molecules. In the sequence of three papers by N.-Q. Trinh, H. Lumbroso and A. Laforque, respectively, considerable detail is given, together with numerous references, of the work on electrical polarization and dipolar moments, and A. Pacault, N. Lumbroso and J. Hoarau in a short article briefly refer to the evidence concerning the structure of molecules to be gained from measurements of magnetic anisotropy.

The two remaining articles in the volume are of a more general nature. The first, by R. Daudel, is of an introductory character and outlines the part played by the de Broglie wave in the study of the structure of molecules, pointing out that there is no difficulty in principle but solely in the numerical solution of the wave-equation applicable to the particular case. The second article, by P. Chanson, describes the various methods used to obtain visual pictures of the atoms and molecules.

Though the lectures were delivered in 1951 and published towards the end of 1953, a useful attempt has been made by several of the authors to bring their material up to the date of publication by the addition in footnotes of brief references to recent important contributions. S. Weintroub

Rotgrünblindheit als Erlebnis

Führer durch die Farbwelt für Rotgrünblinde. Von Dr. Heinz Ahlenstiel. Pp. viii+47. (Göttingen: "Musterschmidt", Wissenschaftlicher Verlag, 1951.) n.p.

THIS little book, which first appeared in 1951 but which has since been translated by Mr. R. W. Burnham and printed privately by the Eastman Kodak Co., is an intriguing attempt by the author to describe the world of colour as seen by the colour-defective, the author himself being a protanope (the type of defective frequently described as red-blind).

Certain aspects of the treatment may seem a little naive, but there are some thought-provoking references both to the difficulties which face the colour-defective and also to effects which the intelligent and observant colour-defective can use to help him. This is well illustrated, for example, in the case of red object colours, which are, of course, a frequent source of confusion to persons with poor colour discrimination. In the first place, as the author points out, red objects possess an abnormally high purity to the colour-defective, even though their basic (defective) hue is yellow; and secondly, many red dyes and pigments are dichroic. This dichroism is such that, in thick layers, the appearance will, to the red-defective, be dark yellow, but in thin or diluted layers a light greyish-blue. Hence, a red surface of paint or fabric is likely to possess, on account of inevitable variations in density of the dye or pigment, a characteristic texture of yellow and blue which will enable the observer to identify the surface as red!

Effects such as these are not readily anticipated by a person with normal colour vision, and this book will prove stimulating reading not only to those interested in colour vision, but also to anyone of a philosophical turn of mind concerned with visual experience. W. D. Wright

The Physics of Viruses

By Ernest C. Pollard. Pp. xi+230. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1953.) 5.50 dollars.

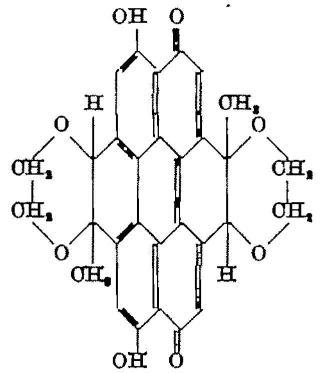
THERE is need for a book which catalogues and describes the many different techniques which the physicist has brought to the aid of the biologist, and especially the virus worker, during the past twenty years. However, it is never quite clear what the intentions of the author of this little book were, and to whom it is really directed. The treatment is too patchy and incomplete to make the work of value as a laboratory manual for the biophysicist, and the numerous erroneous statements about viruses will scarcely commend the book to the pathologist seeking a brief and reliable survey of the physical methods open to him.

The opening sentence consists of a definition of a virus that is so unrestrictive as to include ionizing radiations and many inorganic ions; such carelessness is regrettably only too common in many parts of the book. In Chapter 2, for example, Dr. E. C. Pollard mentions the use of the electron microscope for particle counting, but does not say that special techniques are necessary for the purpose, let alone describe them. Later in the same chapter, the description of, and references to, the techniques for cutting the very thin sections essential for electron microscopy are so incomplete as to be altogether misleading to anyone not already acquainted with the subject, and too many of the few electron micrographs included are of indifferent technical quality. The combined result gives no indication whatever of the range, scope and limitations of the instrument in virus research.

These deficiencies, serious though they are, should not be allowed to obscure the fact that the book does contain what is probably the only short account of the very large amount of work done since 1946 using ionizing radiation as a tool in virus research. Here the author, a nuclear physicist, is on his home ground, and this is easily the best part of the book. There are author and subject indexes, and the book is produced to the high standards one has come to expect of the Academic Press. It is a great pity that the care and obvious ability of the publishers are not matched in the text. H. L. Nixon

CHEMISTRY OF SOME NATURAL PIGMENTS

At the meeting of the British Association this year in Oxford, a symposium was held on September 6 on "Complex Natural Colouring Matters". After a short introduction by Sir Robert Robinson, Sir Alexander Todd gave a lucid account of the recent work which has been carried out in the Cambridge laboratory on the structure of aphins, the pigments obtained from the hæmolymph of various species of Aphidiae. For each species so far examined, the following four types of compounds have to be considered: the water-soluble protoaphins, which are probably glycosides and represent the 'native' precursor of the pigments; the fat-soluble xanthoaphins which are formed after the death of the insect by enzymic action; the orange chrysoaphins representing an intermediate state in the transformation chain; and the deep-red erythroaphins which represent the relatively stable end-products of each series. The two series which have so far been examined in detail are the aphins-*fb* obtained from *Aphis fabae*, the blackfly which attacks broad beans, and the aphins-*sl*, derived from *Tuberolachnus salignus*, the willow aphid. The contribution of Sir Alexander Todd was concerned entirely with the structures of erythroaphin-*fb* and erythroaphin-*sl*. Papers already published in the *Journal of the Chemical Society* have shown that both these two substances have the formulæ $C_{30}H_{[illegible]}O_{8}$, that they contain two carbonyl groups (quinone) and two hydroxyl groups, while the remaining four oxygen atoms are inert and are probably present in an ether linkage. The results of zinc dust distillation and of examination by infra-red and ultra-violet spectroscopy have shown that there is present in both compounds a 4 : 9-dihydroxyperylene-3 : 10-quinone structure. The structure now proposed for the two erythroaphins is based on the following arguments.



Substitution reactions show clearly that positions 2, 5, 8 and 11 in the perylene nucleus are free. Zinc dust fusion yields, among other products, a coronene derivative, suggesting that the saturated part of the molecule is attached to the perylene ring at positions 1 and/or 12 and 6 and/or 7. The formation of acetaldehyde on heating with hot 60 per cent sulphuric acid, and also symmetry considerations, make it appear probable that in these two erythroaphins two dioxan rings are fused with the central perylene nucleus.

Both erythroaphins are optically active, but their specific relations differ markedly. From the fact that erythroaphin-*fb* yields 1·7 moles of acetaldehyde and erythroaphin-*sl* only 0·8 mole, it is deduced that the two alicyclic ring junctions in the former are both *cis*, whereas in the *sl*-isomer one junction is *cis* and the other is *trans*. This deduction is in accordance with modern concepts of the stereochemistry of elimination reactions and also provides a satisfactory explanation of some of the complex interconversion and isomerization reactions of the erythroaphins and their derivatives. Although the structures proposed may not be established with complete certainty, all the known facts, physical and chemical, fit beautifully this ingenious interpretation.

The second contribution, by Prof. R. P. Linstead, was mainly concerned with recent work carried out in the Chemistry Department of the Imperial College of Science and Technology, London, on the chemistry of chlorophyll. This pigment, which plays an important part in photosynthesis in plants, is chemically related to the porphyrins; but, whereas the porphyrins are red and show five discrete absorption bands in the visible and near ultra-violet regions of the spectrum, chlorin, the basic macrocyclic structure present in chlorophyll, is green and is distinguished by a strong and sharp band in the red region. It has been shown, mainly by the work of the late Hans Fischer, that chlorins possess two more hydrogen atoms in the ring system than the corresponding porphyrins, and these additional hydrogen atoms are mainly responsible for the differences in colour and presumably of biological function of these two classes of complex organic molecules. The introduction of these two hydrogen atoms also creates a new element of asymmetry in the molecule and accounts for the optical activity of chlorophyll and its derivatives. Porphyrins are optically inactive, unless they acquire asymmetrical carbon atoms in their side-chains.

The placing of these two hydrogen atoms in the ring system proved to be a particularly difficult problem which was only solved in principle by Fischer in 1940 by oxidative degradation of various chlorophyll derivatives. Oxidation of porphyrins with chromic trioxide has been used for a long time in structural studies; thus with mesoporphyrin, which is related to the protoporphyrin of hæmoglobin, it produces two molecules of ethylmethylmaleimide, derived from the two non-acidic rings I and II, and two molecules of a maleimide propionic acid (hæmatinic acid), derived from the acidic rings III and IV. In 1940, Fischer and Wenderoth succeeded in isolating from a chlorophyll derivative in the form of a silver salt a dihydrohæmatinic acid which was optically active. This observation, together with other available knowledge, indicated that the two hydrogen atoms occupy the β-positions in ring IV. However, Fischer was unable, by the methods then available, to obtain the dihydro acid in a crystalline state, nor was it possible to determine the steric configuration of the compound.

Prof. Linstead and his colleagues have tackled the problem of the 'extra hydrogens' in three ways: in the first place (with Dr. M. Whalley), stable extra hydrogen atoms have been introduced into tetramethyl tetrazaporphin, which is a compound of related structure in which the four methene bridge groups are replaced by nitrogen. This azaporphin took up on catalytic hydrogenation four atoms of hydrogen. On oxidation, good yields of *meso*-1 : 2-dimethyl-succinimide and dimethylmaleimide were obtained, indicating that the hydrogen atoms had indeed entered into the β-positions. This work also demonstrated that the tetrahydride structure involving the β-positions corresponds to a moderately stable reduction-level, at least in the azaporphin series.

Although porphin, the completely unsubstituted porphyrin, had been known for some time, the corresponding chlorin had so far not been synthesized. Prof. Linstead and Dr. U. Eisner have now obtained this substance in the following manner: pyrrole is converted by a Mannich reaction to 2-dimethylaminomethylpyrrole, and this on treatment with a Grignard reagent yields a complex mixture of pigments from which chlorin is isolated in low yield by counter-current distribution and chromatography. The light absorption of the chlorin is extremely close to that observed by Stern with the various natural chlorins supplied by Fischer. Chlorin also gives the correct analysis for a dihydride and can be converted to porphin.

Finally, Prof. Linstead described recent work with Dr. G. E. Fichen on dihydrohæmatinic acid. This compound possesses two dissimilar asymmetric carbon atoms and will therefore exist in two racemic forms. The anhydrides, the imides and various salts of both series have been prepared, and a relatively easy interconversion from one series to the other has been observed to take place. Natural dihydrohæmatinic acid has been prepared by oxidation of pyrrophæophorbide-*a* (a degradation product of chlorophyll *a*) and has been separated from methylethylmaleimide by chromatography on silica gel. The natural substance has $[\alpha]_{5461} = -51°$. In respect of all other properties examined, it closely resembles one of the two racemic materials prepared by synthesis. The configuration of the two asymmetric carbon atoms has not yet been determined, and further developments of this work will be of great interest.

The third contribution, by Dr. A. Neuberger, was concerned with the biogenesis of porphyrins. After a short survey of their biological role, the structure of some of the naturally occurring porphyrins was briefly discussed and the point was emphasized that all the porphyrins associated with proteins are formally derivable from ætioporphyrin III, that porphyrins of type I are also found in Nature, while isomers of the series II and IV are apparently not synthesized by living matter.

From the wide distribution of cytochromes and catalase it can be deduced that almost all cells can synthesize porphyrins, but up to eight years ago there was no information as to the nature of the precursors. However, in 1946, Shemin and Rittenberg showed by means of labelling with heavy nitrogen that the nitrogen of glycine is used in a highly specific manner in the synthesis of protoporphyrin. Later work done in the United States by Shemin and in Britain by Muir and Neuberger produced convincing evidence that all four nitrogen atoms of porphyrin are specifically derived from glycine. When carbon-labelled glycine became available, it was shown by Altman that the carboxyl carbon atom of glycine is not incorporated into porphyrin, while parallel work done in the Columbia laboratories and at the National Institute for Medical Research, Mill Hill, demonstrated that the methylene carbon atom of glycine was used. In fact, for each nitrogen atom of glycine two methylene carbon atoms were found to be incorporated into each of the four basic units. By oxidative degradation it was found that one of these glycine methylene carbon atoms gives rise to the methene bridge, while the other is incorporated into the pyrrolic ring. Later, it was shown by Shemin that one of the two α-carbon atoms originates from the second glycine methylene group. This, of course, accounts only for eight out of thirty-four carbon atoms of protoporphyrin. Experiments with carbon-labelled acetate carried out in Columbia and at Mill Hill suggest that α-oxoglutarate and a substance closely related to it provide all these other carbon atoms; but it has been finally shown by Shemin that the substance concerned is mainly a succinic acid derivative substituted on one of the carboxyl groups, probably the coenzyme-*A* complex of this dicarboxylic acid. The position thus is that each of the four basic units of uroporphyrin can be thought to be formed by condensation of two molecules of glycine with two molecules of a succinic acid derivative and that one of the two nitrogens and the two carboxyl groups of glycine are lost before, during or after this condensation.

The identification of the intermediate between glycine plus succinic acid and the porphyrins has proved to be a difficult task and is by no means completely solved. Neuberger and Muir considered that the basic unit is a pyrrole substituted on one of the α-positions with elements of a potential methene group. This may have been formed by an initial condensation of two glycine molecules followed by combination with succinic acid. However, work with substances such as β-hydroxy aspartic acid was discouraging, and this idea was discarded also for other reasons. If the basic pyrrole has already one of the two α-positions substituted, it is easy to see how the symmetrical porphyrin of type I is formed, but the synthesis of the asymmetrical type III is more difficult to explain. A more reasonable assumption was that the basic pyrrole has two free α-positions, and this pyrrole would then combine with a further molecule of glycine giving one or other of two different α-substituted substances. It was therefore assumed that glycine would condense with succinic acid giving, in the first place, α-amino β-oxoadipic acid which would then be converted by loss of carbon dioxide to δ-aminolævulic acid. This acid might then react with a further molecule of succinic acid to give δ-succinamidolævulic acid, which could be reduced to the hypothetical pyrrole. However, biological experiments showed that the succinamido compound is inactive.

In the meantime, Westall had crystallized porphobilinogen, a substance excreted by patients suffering from acute porphyria. Its structure has been established by Cookson and Rimington as a pyrrole having an acetic acid and a propionic acid side-chain in the two β-positions and an aminomethyl group in one of the two α-positions. Soon afterwards Falk, Dresel and Rimington showed that porphobilinogen behaves as a porphyrin precursor, and it thus seems that the original idea of the Mill Hill workers may be partially correct and that an α-monosubstituted pyrrole is the first cyclic intermediate in the synthesis. From the structure of porphobilinogen it can be inferred that δ-aminolævulic acid itself might be the sought intermediate. This was shown almost simultaneously by Shemin and Russell and by Neuberger and Scott, and confirmed by Falk and Dresel. Recent work at Mill Hill, which was briefly reported by Dr. Neuberger, has greatly strengthened this concept that glycine and succinic acid combine to give δ-aminolævulic acid, which gives rise to porphobilinogen and then to porphyrins.

DUKINFIELD HENRY SCOTT (1854–1934)

By DR. AGNES ARBER, F.R.S.

A PALÆOBOTANIST, writing in the early nineteen hundreds, spoke of D. H. Scott as then belonging to the same class as Nathorst and Zeiller—these three standing head and shoulders above all others in fossil botany. For Scott this verdict is certainly borne out by his long series of books and memoirs, which covers a period of forty years (1894–1933). So many well-documented obituary notices are accessible (see list at the end of this article) that it would be superfluous to reiterate the facts of his career. In this, his centenary year, I propose to confine myself to a few special aspects of his life and work.

Scott's inborn trend towards a life of research was fostered by his personal circumstances. At the age of thirty-eight he became honorary director of the Jodrell Laboratory at Kew, and from this time onwards he was free from the daily grind of academic duties. Fourteen years later he retired into the country, thus securing a still more leisurely and unhampered existence; but, while he enjoyed the liberty of the amateur, he did not suffer from the amateur's drawbacks. He had been disciplined by reading classics at Oxford; then by an engineering training; and, later, by ten years of teaching—a long enough time to put him in possession of all that this particular form of experience had to offer him. Moreover, the absence of enforced day-to-day contacts did not involve any isolation from the scientific world. Indeed, fifty years ago he had become the focal centre of British botanical life to a degree that now, in this period of specialization and sub-division of the subject, would be impossible for any one man. His commitments included such responsibilities as the chairmanship of the Editorial Board of the *Annals of Botany*, and he did much work in connexion with the learned societies to which he belonged; he also gave unstinted time and thought to helping other research workers, whose indebtedness to him can scarcely be exaggerated. None of these doings was of a mechanical type, and they all lay in the field of his genuine interests and his chosen subject; they left his mind unstrained, so that he could put the best of himself into his studies.

In thinking about D. H. Scott, comparisons with Charles Darwin (forty-five years his senior) present themselves unbidden. Both men had the advantage of freedom from monetary cares, so that liberty and independence came to them naturally; and they had each a happy domestic existence, with an extensive but close-knit background of kith and kin. The minds of both were not so much remarkable for brilliance as for the unwearying tenacity which enabled them to pursue the same problems continuously over many years. This power of dwelling on a subject steadily for an indefinite period was one that Darwin recognized in himself, and it is known to have been a principal factor in the process through which Newton's discoveries came into being. Possibly it was this concentrated tenacity which induced in both Darwin and Scott a strict canalization of all mental energy into science; at least in later life, no branch of literature or of the arts can be said to have played an essential part in the existence of either of these biologists. Another resemblance, which though trivial is perhaps not without significance, is that both men inclined to a certain informality in the presentation of their material. This was partly, I think, a reaction against the pomposity of the professional pundit, and partly an eager desire to appeal to a wider circle than that of initiates. It may be recalled that Sachs expressed regret about the style of writing which Darwin adopted, on the ground that it degraded the severity of scientific thinking (cf. Pringsheim, E. G., "Julius Sachs", p. 167; 1932). Darwin's slightly casual approach finds some parallel in Scott's books, and also in what has been called his 'hearth-rug' manner of addressing scientific meetings. Underlying even such petty resemblances, there was undoubtedly a fundamental affinity between Scott and Darwin, which expressed itself in Scott's glowing, though not uncritical, admiration of Darwin's work.

The gains that have accrued to science from the technical progress of the present day, and from the resulting development of team-work research, are as obvious as they are vast; but they are correlated with certain losses, none the less real because they are less tangible. There is one loss, especially, that may in the long run prove tragic. It is that, as the amateur (but not amateurish) pursuit of science—typified, respectively, in a major and a minor form in Darwin and in D. H. Scott—becomes more and more impracticable, contemplative leisure fades irrevocably from scientific life. That uninterrupted periods of still meditation are essential, if the deeper insight is to be won, was recognized even long ago, when the *tempo* of day-to-day existence was much quieter than in our mechanized age. In the seventeenth century, Descartes affirmed that liberty and leisure were a necessity for the purposes of concentrated thought; moreover, he acted on this belief, betaking himself to exiled retirement, to avoid time-consuming distractions. Spinoza, again, though he was not, like Descartes, a man of means, declined a professorial chair, basing his refusal partly on the conviction that he could only teach a class at the sacrifice of his research in philosophy.

Though D. H. Scott's achievements were conditioned by his unhurried existence, which made continuous thinking possible, this does not imply that he consciously adopted the contemplative attitude. My impression is that he was not disposed to give any spontaneous consideration to processes going on in his own mind, though in correspondence he might sometimes be stimulated into revealing a defined position. He wrote to me in 1931, when he was in the seventies: "your letter causes me to enter on the religious duty of self-examination! . . . But am I an Aristotelian or a Platonist? When I read a little of the old philosophers some 55 years ago, my sympathies were certainly with Aristotle, who appeared to talk fairly plain sense. I could make nothing of Plato's philosophy, though I admired his style. . . . My interest is pure Natural History. I like to see things as they are, and to think how they became so. I don't care for Physiology. . . . But neither do I care a bit for . . . 'final patterns, eternal moulds'—all mere imaginations of the philosophising brain". In an earlier letter he had stigmatized logic as "a deceitful guide"; in his own work he relied on a strictly empirical procedure. Empirical conclusions demand, however, a theoretical basis; this, in Scott's case, took the form of a fundamental belief that "similarity (suitably determined)", distinguished from that which could be recognized as "superficial", might be accepted unquestioningly as "a mark of blood relationship". This belief was stressed in a correspondence which I had with him, in 1930, about parallelism in evolution, as contrasted with the older picture of a monophyletic genealogical 'tree' of the plant world; the visual image of such a 'tree' had, indeed, served him throughout his studies as the frame of reference for his botanical thought. He wrote: "When I have occasionally seemed to favour parallelism ('up to a certain point, you know'—like Mr. Brooke in 'Middlemarch') my idea has not been a bundle of sticks separate all the way up, but rather a Lombardy Poplar, with a trunk bearing a number of long, parallel branches". This partial acceptance of parallelism was an instance of Scott's anxious desire not to turn a blind eye upon arguments militating against his views; he was, moreover, prepared to discard his most cherished theories as soon as he had brought himself to feel that knowledge acquired since his conclusions were reached had proved his evidence to be less than adequate. A cogent example is his relinquishment of the idea of the filicinean origin of seed-plants, which had meant much to him. It is recorded that he was fond of quoting Pope's couplet:

> "And spight of Pride, and in thy Reason's spight,
> One truth is clear; 'Whatever Is is RIGHT'."

This loyalty to abstract truth had, however, to contend with an innate conservatism, involving a lesser loyalty to the purely Darwinian scheme of things, which had dominated his younger days. As a general attitude to life and to religion, the tolerant form of nineteenth-century agnosticism, which seemed the most consistent position for a convinced Darwinian, was congenial to Scott's turn of mind; but, in his later years, his views tended somewhat more in the direction of theism.

It is perhaps not too far-fetched to suggest that certain traits in D. H. Scott's scientific personality were inherited from his great-grandfather in the paternal line, the Rev. Thomas Scott (1747–1821); D. H. Scott's mother could claim collateral descent from the same cleric, so that there was more than the normal chance of the reappearance of hereditary characters derived from him. To-day, Thomas Scott is most vividly remembered for his friendship with Cowper, and for the fact that "John Gilpin" was first adumbrated under his roof, though not by him. He was, in his time, known widely as a Biblical commentator. In his spiritual autobiography, "The Force of Truth" (edit. 1, 1779), he set forth the process he had gone through in reaching his religious convictions. The passage may be quoted, since it is just what his great-grandson, D. H. Scott, might have written, if he had analysed in eighteenth-century parlance his own cautious and balanced scientific method: "I sat down very coolly to search for the truth, I proceeded very gradually, and with *extreme caution*; I took no opinion upon trust; I gave up none of my sentiments, until the arguments by which I had learned to defend them were satisfactorily answered; nor did I admit any new articles into my creed, till either every objection was obviated, or I was pressed on the other hand with such as were still more unanswerable" (quoted from the 1821 edit.).

D. H. Scott's most conspicuous impact on the study of plants has been through his classic corpus of memoirs on structural palæobotany, begun under W. C. Williamson's inspiration; but a more general effect has radiated from his original training in research (1880–82) under Julius Sachs. Scott himself said that going to work in a German laboratory, when he was in his twenties, was, to him, like a pilgrimage to Mecca to a pious Mussulman. It was fortunate that, at Thiselton-Dyer's suggestion, he decided upon the University of Würzburg, since it is no exaggeration to say that Sachs possessed one of the finest minds that have ever been devoted to plant study. Goebel, his assistant, who was about Scott's age, had been a pupil of Hofmeister (born 1824), and was thus a link with the heroic age of German botany. Sachs himself bore the impress of a wider and deeper intellectual tradition. The Czech physiologist, Purkinje (born 1787), who has been described by Nordenskiöld as ranking among the great geniuses of biological discovery, employed Sachs, from the age of eighteen, as his personal assistant. This relation with Purkinje meant that Sachs, in his formative years, had intimate contact with a man who had been directly influenced by Goethe, for it was the "Farbenlehre" that had stimulated Purkinje's early studies in the physiology of sight, and had led to his friendship with the poet. Sachs's school at Würzburg thus inherited some of the best elements in the stream of biological thought which can be traced back to the Goethe period. After Scott's sojourn in Germany, he introduced unconsciously, wherever he might find himself, the spirit of research with which he had been imbued in Sachs's laboratory, and this spirit—passed on through a succession of younger botanists—continues to work as a living leaven among students of the plant world.

Accounts of D. H. Scott's life and work, in alphabetical order of authors' names: Arber, A., "Dict. Nat. Biography", Supp. 1949, for 1931–40; Oliver, F. W., *New Phyt.*, 33, 73–76 (1934); Oliver, F. W., *Ann. Bot.*, 49, 823–40 (1935), with bibliography by Edwards, W. N., and Wonnacott, F. M.; Rendle, A. B., *J. Bot.*, 72, 83–88 (1934), with D. H. Scott's autobiographical notes; Sahni, B., *Current Science*, 2, 392–95 (1934); Scott, D. H., *New Phyt.*, 24, 9–16 (1925) (reminiscences of research in Germany); Scott, D. H., in Oliver, F. W., "Makers of British Botany", 243–60 (1913), for Scott's precursors in fossil botany, and especially for his relation with W. C. Williamson; Seward, A. C., *Nature*, 133, 317–19 (1934); Seward, A. C., Obit. Notices Fellows Roy. Soc., 205–27 (1934); Weiss, F. E., *Proc. Linn. Soc.*, Session 146, 1933–34, 166–69.

BRITISH WELDING RESEARCH ASSOCIATION

OPEN DAYS

THE laboratories of the British Welding Research Association, at 29 Park Crescent, London, W.1, were open for inspection during November 23–24, the previous occasion being in February 1950. Visitors may well have been surprised at the evident expansion in research effort, with the corollary increases in research facilities, equipment and number of staff during the space of but a few years.

The main research effort is divided equally between steels and the light alloys, though visitors heard and saw something of the working of the Liaison Department, the Library and Information Services, and the other and minor research activities now in hand.

One of the most interesting developments from the steel welding researches is a method for the assessment of weldability of high-strength low-alloy steels by means of a dilatometric method. This method depends on the relationship between hardened-zone cracking and the temperature at which transformation ceases in the hardened zone. This simple means of assessing weldability was demonstrated. Also on view was some of the work using weldability cracking tests which has led to this development.

Mechanical tests at very high temperatures are being made on specimens cut from weld metal, and the results related to the defect known as hot cracking. In these tests, a 6-kVA. high-frequency generator is used. A wider range of investigation of the same problem is being made, using the 'Murex' hot-crack machine.

An investigation is being made of the problem of fissuring in weld metal; that is, the occurrence of very fine intergranular cracks. It has been found that these are liable to occur for given threshold values of hydrogen content and cooling-rate.

Visitors saw something of some relatively new work on the welding of structural steels, using the self-adjusting arc process. The field of high-temperature brazing was represented, and creep tests of brazed turbine assemblies were in progress.

Good progress has been made in the microscopical identification of inclusions in steel plate and weld metal, using a Reichert *MeA.* metallurgical camera (with polarizing equipment) and a Reichert 'Zetopan' metallurgical microscope for visual work. Here the use of diamond dust for the preparation of metallographic specimens has been invaluable; the technique was demonstrated.

Apart from routine chemical analysis, micro-gas analysis has been increasing in importance during recent years. The latest methods for the determination of hydrogen by vacuum extraction were shown, and the way that these have been adapted to deal with the problems of determining hydrogen, not only in weld metal but also in the parent wire and plate materials. One interesting problem has been the determination of the relative amounts of hydrogen dissolved in the aluminium welding wire and that produced by reaction from corrosion products on the surface. These experimental investigations sometimes require the artificial introduction of hydrogen, and this is done by means of cathodic charging.

The light alloy researches cover a fairly wide range of welding processes and aluminium (and magnesium) alloys, but certain problems with respect to heat flow, dilution effects and porosity have been found to be basic to this field of study.

The work on heat flow, which is derived from an investigation of the welding of heat-treatable alloys, is concerned with the production of basic formulæ by means of mathematical analysis, in parallel with measurements of the thermal cycles characteristic of the weld pool and various positions in the parent plate. Methods have been developed for the location of thermocouples in the plate metal, and also in the weld pool itself. The temperatures can be recorded using a ciné camera with a sensitive millivoltmeter, or, where faster rates are involved, using a cathode-ray oscillograph with a d.c. amplifier and camera. It has been found that the arc and weld pool cannot here be treated as a point source, and some progress has been made in the determination of weld pool shapes by calculation.

An important advance has been made respecting the dilution effect; that is, the extent to which the composition of the weld metal is changed by dilution with melted parent-plate material. Nomograms have been prepared to facilitate the estimation of weld metal composition obtained with particular welding conditions. This has been found to be important in the metal-arc welding of *H*.10 plate and in the tungsten-arc welding of a high-strength heat-treatable aluminium alloy, in particular with regard to the development of suitable filler-wire compositions. In the assessment of joint properties in light alloy materials, porosity is especially important. For the measurement of porosity a code has been drawn up for its assessment under the microscope, following detailed investigations. Visitors were able to see the method used for the measurement of elongation over small gauge lengths, found necessary to investigate the variation in ductility across a welded joint. Various forms of weldability cracking tests were shown, in some of which slotted plates are used to give quite severe conditions without the necessity of employing rigid and cumbersome jigs.

Investigations are also in progress on a number of specific alloys, including the metal-arc welding of *H*.10 plate from the point of view of eliminating cracking and porosity, the development of improved filler materials for *H*.14, *H*.15 and *D.T.D*.683 alloys, and the self-adjusting arc welding of *NP*.5/6 alloy.

The relatively new self-adjusting arc process has naturally required some investigation, and, in particular, work on the fundamental characteristics of the process has been done in co-operation with the Electrical Research Association. The effect of power source characteristics on the degree of self-adjustment has been determined. In parallel, work has been done on drift in power source output. This is making possible the development of idealized generators for the process, or at least the modification of existing generators in this direction. The efficacy of the improved power source characteristics was demonstrated by comparative welding tests over a stepped plate.

OBITUARIES

Sir John Lennard-Jones, K.B.E., F.R.S.

THE death on November 1 of John Edward Lennard-Jones has deprived British theoretical chemistry of its most senior and distinguished representative. Yet he did not begin his career as a chemist. Born in 1894, he was educated at the University of Manchester and then at Trinity College, Cambridge. The First World War interrupted his studies and he became a flying officer (pilot) in the R.F.C. and later experimental officer at the Armament Experimental Station, Orfordness. In 1919, however, he returned to the University of Manchester, this time as lecturer in mathematics. This post was followed by a readership in mathematical physics and later the first professorship in theoretical physics, both at Bristol. It was during this time that he became deeply interested in the nature of interatomic forces, and introduced the semi-empirical law of force $a/r^n - b/r^m$ with which his name will always be associated. These Bristol years were productive of other new ideas, and in particular it was then that Sir John initiated the wave-mechanical study of molecular structure in the form of molecular orbitals. His first paper on this topic, published in 1929, is still a standard piece of work, and the whole subject owes a great debt to him for the way in which he brought out in a simple way the mathematical implications of experimental studies on quantum numbers in molecules then being made by R. S. Mulliken and others.

This migration from mathematics through physics to chemistry made him an excellent holder of the John Humphrey Plummer chair of theoretical chemistry established at Cambridge in 1932. At the same time (1933) he was elected a Fellow of the Royal Society. This post at Cambridge was—and still is—the only chair of theoretical chemistry in Britain. While he was in Cambridge, Lennard-Jones (or 'L. J.' as he was known to his many friends) laid the foundations of the present vigorous school of theoretical studies in Britain. During this time he extended his earlier work on molecular orbitals, he made some useful progress in the very difficult field of chemical interactions at a metal surface, and he developed the 'cage-model' of liquids. Had it not been for the Second World War, in which he played a conspicuous part as Superintendent of Armament Research and Director-General of Research (Defence) at the Ministry of Supply, there is no doubt but that he would have done even more.

At the end of the War, Sir John returned once more to Cambridge, and although he became chairman of the Scientific Advisory Council of the Ministry of Supply, he and his younger colleagues completed an extensive study of the most fundamental problem in all chemistry—what is meant by a chemical bond ? But by this time his administrative abilities were becoming widely known. He was a member of the Advisory Council for the Department of Scientific and Industrial Research, a member of the Scientific Advisory Committee of the National Gallery, and president during 1948–50 of the Faraday Society. His quiet manner and understanding approach to difficulties made him an excellent chairman on all occasions where conflicting claims had to be reconciled. It was not surprising, therefore, that in April 1953 he was invited to follow the late Lord Lindsay and become the second principal of the new University College of North Staffordshire at Keele. He threw himself whole-heartedly into this work, which he so evidently liked, and in which he had become much appreciated, not only in the College itself, but also in the neighbourhood.

Sir John received many honours. He held the D.Sc. of Manchester and the Sc.D. of Cambridge; he was made K.B.E. in 1946, was awarded the Davy Medal of the Royal Society in 1953, and an honorary D.Sc. at Oxford on the occasion of the British Association meeting there only a few weeks before his death, when he was president of Section B (Chemistry). He had recently been awarded the Longstaff Medal of the Chemical Society. All those who knew him respected the complete integrity of his life, the exceptional simplicity and clarity of his lectures and his obvious enjoyment of everything that he did. His home life was a most happy one; he is survived by his widow, a son and a daughter.

C. A. Coulson

Mr. B. H. St. J. O'Neil

The unexpected death on October 24 of Brian Hugh St. John O'Neil at the age of forty-nine has deprived the Ancient Monuments Department in the Ministry of Works of the chief inspector who followed Mr. J. P. Bushe-Fox, whose death was so recently recorded in these pages (*Nature*, November 6, p. 860).

Educated at Merchant Taylors' School and St. John's College, Oxford, of which he was a scholar, Mr. O'Neil began a career in the City of London, but soon deserted to Westminster and the Ancient Monuments Department in fulfilment of interests always near his heart. His most particular delight was in medieval and post-medieval fortifications and in early artillery, of which he had a profound and detailed knowledge, well employed, for example, in a recent visit to advise upon the treatment of early Portuguese fortifications in West Africa. He spoke and wrote of these matters with an authority and relish good indeed to meet. But his work extended also with distinction to other fields. He was no mean numismatist, as his classic study of Theodosian silver coin-hoards in late fourth-century Britain proves. He could take a prominent part in discussions concerning late-Roman copies of earlier coinage. No less notable was his discussion of the Silchester dykes and their relation to Britons and Saxons. Among his field-work should be specially cited his excavation of Frith Ffaldwyn Iron-Age fortress in Powys and the Caerau settlement in North Wales, and the unstinting unofficial help accorded in the excavations by his wife of Roman villas at Park Street, Whittington Court and Bourton-on-the-Water.

His appointment as chief inspector of ancient monuments brought him into close quarters with war-time and post-war problems in archæology. The application of State aid to the examination and record of sites threatened by destruction was liberally and wisely interpreted by him, and presently extended to cover sites of national importance which private resources, impoverished by taxation and inflation, were no longer equal to tackling. This was a valiant service to knowledge of which the full effects are not yet apparent, for he was planning publication in promising fashion, talking of the matter with the writer less than a week before his death. We have lost far too soon a judicious innovator, a good (if perhaps fatally self-sufficient) administrator, a zealous public servant, a keen scholar and a staunch friend, who in all these capacities will be widely and deeply mourned.

I. A. Richmond

Miss Rosamund F. Shove

After a long illness borne with great fortitude, Miss Rosamund F. Shove died on October 17 in Richmond Hospital, aged seventy-six. Until the last few months of her life she had hoped to renew some of her many activities in the field of science and remained keenly interested to the end. Educated at Girton (1896–99), Miss Shove was trained in research by Prof. A. C. Seward; and in 1900 "The Morphology of the Stem of *Angiopteris erecta*" appeared in the *Annals of Botany*. Miss Shove's professional career included seventeen years of science teaching in schools, followed by twenty years of university and training college work in biology and hygiene. Her last post was at the Maria Grey Training College (1921–38). She served on the council of the Linnean Society during 1943–47.

In 1937 Miss Shove became honorary secretary of the School Nature Study Union, and in 1940 undertook the editorship of its journal, *School Nature Study*, at a critical time. She sustained both the Union and the journal throughout the War and continued her labours until 1953, when the jubilee number was published. The journal had appeared regularly each quarter, thanks to her tireless devotion.

At the British Film Institute, Miss Shove was a faithful member of a volunteer panel who viewed natural history films from many sources. She contributed many film and book reviews to *School Nature Study*, besides several illustrated articles based on her discriminating observations; for example, a life-history of a beautiful, ineradicable weed, a pink-flowered *Oxalis*.

Her small garden at Kew contained many cherished plants, some under glass; in the large collection of dwarf trees, each in its own pot, are an English elm forty-two years old and a youthful common lime. I was delighted to learn that this collection had been accepted recently for the Royal Botanic Gardens, Kew.

Other evidence of the lasting influence of a gifted botanist will be passed on by her many grateful pupils, students, colleagues and other friends.

MADELINE MUNRO

NEWS and VIEWS

Botany at Singapore: Prof. R. E. Holttum

PROF. R. E. HOLTTUM, who was the first professor of botany in the University of Malaya, has just retired after spending the greater part of his life in Malaya. He intends to live at Kew, where he will continue his studies on Malayan plants, particularly ferns. Prof. Holttum was born at Linton in Cambridgeshire and was educated at Bootham School, York, and St. John's College, Cambridge. He took the Natural Sciences Tripos with first-class honours in Parts I and II, winning the Frank Smart Prize in 1920. He first went to Malaya in 1922, when he joined the staff of the Botanic Gardens. He was appointed director of the Gardens in 1925, and remained at this post until 1949, when he joined the newly created University of Malaya and brought the Department of Botany into being. Prof. Holttum's appointment was particularly valuable in the early and formative years of the University, for he has travelled widely through Malaya, Borneo and Indonesia and has an unparalleled practical knowledge of the flora of this region. During the past five years he has been very active and has set a tradition that his successor will find it hard to surpass. He has published many papers on ferns, bamboos, gingers and orchids, which are his principal botanical interests, and the past two years have been marked by the publication of some of his major works: "Orchids of Malaya" (Singapore, 1953), "Gardening in the Lowlands of Malaya" (Singapore, 1953), "Plant Life in Malaya" (London, 1954); a fourth volume, "Ferns of Malaya", is in the press. Prof. Holttum's activities in Singapore have been by no means confined to botany, for he has taken a leading part in various important societies. He will be remembered with affection by his students, his colleagues and his many friends in Singapore, who wish him a long and happy retirement near the Royal Botanic Gardens at Kew.

Research in British Power Industries: Gas and Electricity

IN a debate in the House of Commons on November 9 on the annual reports and statements of accounts of the gas and electricity industries, the Minister of Fuel and Power, Mr. Geoffrey Lloyd, said that he had agreed with the Gas Council for capital expenditure this year of £61 million. Electricity development was estimated by Lord Citrine at £1,250 million over the next six years; it should provide 1·6 million kilowatts next year and 1·95 million kilowatts in 1959. This includes a five-year programme costing £50 million to bring electricity to 70 per cent of the farms and 80 per cent of rural housing of Britain. In the first half of this year, industrial consumption of gas increased by 8 per cent and that of electricity by 14 per cent; but the gas industry had saved 250,000 tons of coal last year and the electricity industry 1 million tons. Mr. Lloyd also referred to research on the utilization by the gas industry of inferior and cheaper coals, and to the discovery of a process for making gas from fuel oil alone, for which sixteen new plants are being erected. Questioned by Mr. A. Robens as to whether sufficient money was being spent on research in these two industries, the Parliamentary Secretary to the Ministry, Mr. L. W. Joynson-Hicks, said that the figures quoted by Mr. Robens, £229,000 for the gas industry and £242,900 for the electricity industry, did not represent anything like the full expenditure on research of these two industries. Much of the expenditure, he said, is of a capital nature which is not specifically allocated to research; much work is also being done by the British Electrical and Allied Industries Research Association, and the British Electricity Authority contributes to research being carried out by at least half a dozen other bodies. He promised to attempt to obtain a figure for the total expenditure on research by the industries, but was of opinion that research is not being held up on financial grounds.

Nuclear Power

MR. LLOYD, referring to nuclear power, emphasized the dependence of industrial power from this source upon the ordinary electricity supply system, the expansion of which is already being planned to feed industry from nuclear power stations when the practical difficulties have been overcome. Mr. Lloyd explained why at present in the experimental atomic power stations steam generation is not close-coupled with the furnace, and also referred to the problem of nuclear fuel and the possibility of utilizing as fuel most of the uranium extracted from the ore. Engineers from the British Electricity Authority are already attending training courses at Harwell, and from now on there will be a steady stream of electrical engineers attending these courses. The British Electricity Authority is collaborating closely with the Atomic Energy Authority, and also with the plant manufacturers, in the design of experimental nuclear power stations by making freely available its experience regarding turbines and power-station construction generally. Mr. Lloyd also said that, with the view of encouraging enterprise and, where proper, a spirit of adventure, the Government has decided to encourage these two nationalized industries to compete with each other as actively as possible and with the oil industry. In the course of the debate, Mr. G. Nabarro expressed the opinion that the prototype and pilot nuclear power station at Calder Hall, with a capacity of 60,000 kW., would be completed by the end of 1956, and that such plants would be making a substantial contribution to grid supplies of electricity well within ten years. Mr. Joynson-Hicks, however, maintained that it would be unreasonable, in view of the vast amount of work and planning to be carried out, apart from research, to expect nuclear energy to be available on a large scale commercially through the grid system of Britain within less than about ten years. He also said that the Government will not overlook the importance of keeping a balance in capital expenditure on the development of nuclear power, on electricity supply generally and on the coal industry.

Nuffield Foundation Grant for Colonial University Colleges

THE Nuffield Foundation has announced that it is setting aside £250,000 for the benefit of the new Colonial university colleges. From this capital sum the University College, Ibadan, Nigeria, and the University College of the West Indies, Jamaica, are to receive grants of £50,000 each; grants to other Colonial university colleges, including a scheme of research into education in the Colonies, are being considered by the Foundation. At Ibadan, £5,000 of the £50,000 grant will be used to build and equip a house—to be known as Nuffield House—for academic visitors. The balance of £45,000 will be held and invested by the Foundation, and the income from this sum for five years will be used to finance a Nuffield visiting professorship for Nigeria. At the end of five years the scheme will be reviewed by the College and the future of the fund will be decided. The first Nuffield visiting professor to be appointed to Ibadan is Prof. P. W. Richards, professor of botany in the University College of North Wales, Bangor, who has published many papers on tropical rain forests. The £50,000 grant to the University College of the West Indies, near Kingston, Jamaica, will be invested in a fund to be known as the Nuffield Endowment Fund. The income from the Fund will be used by the College to finance pilot projects. The choice of projects will rest with the College Council, without emphasis on any particular subject or type of study. The progress of any project so assisted will be reviewed at the end of five years.

Archives of Machine Design: New Polish Journal

THE first number of a new engineering quarterly journal has just appeared; it is entitled *Archiwum Budowy Maszyn*—literally, *Archives of Machine Design*—and is sponsored by the Machine Design Committee of the Polish Academy of Science (Tom 1, Zesyt 1; pp. 120. Warszawa: Polska Akademia Nauk, 1954; 15 zlotys). Summaries of five hundred to a thousand words, in Russian and English, are given at the end of each contribution. This issue comprises four papers of twenty to thirty pages each and one of less than ten; they range over a wide field of mechanical engineering science and treat essentially practical problems from a scientific point of view. The first two papers, on safety factors and a statistical approach to the analysis of failures, respectively, lead to criteria for the more economic design of machine elements. A paper on the conductivity of fibrous insulating materials reports some pure research work with theoretical analysis of the results, some of which are novel. The final paper introduces an improved method for the design of internal combustion engine cams, involving a parabolic variation in the acceleration as a function of time; with the design information given, such a cam should be more effective than the traditional type and no harder to design. This new journal, which shows an outlook intermediate between the German and the Russian, is undoubtedly to be welcomed.

Microscopy of Metals

SINCE Sorby in 1864 first published an account of his work on the microscopic examination of the etched structures of metals, and after an incubation period of nearly two decades, the importance of the microscope in both theoretical and industrial metallurgy has increased greatly. During the past twenty or twenty-five years, in particular, the rate of advance has been spectacular, and the use of polarized light, dark-ground illumination, phase-contrast and the reflecting microscope, among other techniques, has increased its scope of utility enormously. It was therefore appropriate that the refresher course of the Institution of Metallurgists in 1953 was devoted to a consideration of these new, and in some directions quite exciting, techniques. The papers presented are now published by the Institution (pp. 132; from the Institution, London, 1954; 15*s*. 6*d*.) and provide an account, not easily available elsewhere, of the help that the modern microscope can give in the examination of metals and alloys. Five lectures are reprinted, two of which deal with the principles of the microscope and, in particular, of these newer techniques, and with the preparation and examination of the sample. There is then an extended treatment of the use of polarized light and of phase-contrast and interference metallography, and, a matter of growing importance, of the hot-stage microscope for the examination of materials at elevated temperatures. In this publication a condensed but sound account is given of the general, present position, and there are few microscopists interested in this field who will not benefit from its study. The papers are well illustrated by a large number of photomicrographs, and, though a few of these show too clearly from the 'screen' that they are reproductions, the general standard is good.

Cave Sites of the Mogollon Culture in New Mexico

THE finds from the cave sites of the Mogollon culture of west-central New Mexico are of no great antiquity; indeed, the earlier ones do not date before 1100 A.D. and the later group perhaps to 1300 A.D. But they are no less interesting for that, and the careful study of four cave sites, two of them containing cliff dwellings, by Paul S. Martin, John B. Rinaldo and Elaine Bluhm, has been well worth while (Fieldiana–Anthropology, Vol. 42: Pub. 731 of the Chicago Natural History Museum; pp. 227; 1954; 2 dollars). The culture of the Mogollon Indians has long been under investigation, but these are the first cliff dwellings that have been carefully dug and of which the details have been published. The caves occur in New Mexico in the Pine Lawn valley district. The excellent illustrations make it easy to follow the excavations. After describing the digs, a critical study of the pottery and other finds from the various levels follows. Several different types of arrow head were unearthed, and it is interesting to learn that certain types go with certain styles of pottery and seem to be characteristic of certain levels. This may prove to be an important check on studies elsewhere based exclusively on the pottery sequence. The volume is very well put together, and altogether constitutes an excellent piece of work.

An Actinophage for Potato Scab

A NUMBER of actinophages active against species of *Streptomyces* have already been reported. In a recent paper, F. H. S. Newbould and E. H. Garrard have described the isolation of a phage specific for *S. scabies*, the pathogen of potato scab (*Canadian J. Bot.*, 32, No. 3, 386; 1954). This phage was isolated from soil surrounding scab-infected potatoes. Tested against fifteen scab-producing *Streptomyces* cultures isolated from scab lesions, thirteen were lysed, one partially lysed and one was resistant. Against fifteen non-scab-producing strains of Actinomycetes, also isolated from scab lesions, thirteen were not lysed and two showed evidence of partial lysis. Tested against Actinomycetes cultures isolated from soil, the phage was less specific and the results were inconclusive. Lack of phage specificity is attributed to variation among *Streptomyces* cultures.

The Night Sky in December

FULL moon occurs on Dec. 10d. 00h. 56m., U.T., and new moon on Dec. 25d. 07h. 33m. The following conjunctions with the moon take place: Dec. 2d. 16h., Mars 6° S.; Dec. 12d. 22h., Jupiter 3° N.; Dec. 21d. 15h., Saturn 6° N.; Dec. 21d. 20h., Venus 7° N.; Dec. 31d. 12h., Mars 6° S. In addition to these conjunctions with the moon, Venus is in conjunction with Saturn on Dec. 16d. 00h., Venus 0·7° N. Mercury, a morning star, rises 1h. 20m. before the sun on December 1 and draws nearer the sun during the remainder of the month; it will not be easily seen at any time during December. Venus, a morning star, rises at 5h. 40m., 4h. 40m. and 4h. 20m. on December 1, 15 and 31, respectively; its stellar magnitude varies between $-4\cdot0$ and $-4\cdot3$, and the visible portion of the illuminated disk between 0·08 and 0·34. It is interesting to notice that the planet becomes brighter in spite of its increasing distance from the earth—from 28 to 45 million miles during the month—the increase in brightness arising from the large increase in the visible portion of the illuminated disk. Mars is an evening star, setting about 22h. 15m. during December: stellar magnitude 0·5–0·8, and the visible portion of the illuminated disk 0·862–0·881. The decrease in brightness, in spite of the increase in the visible portion of the illuminated disk, is due to the increase in the planet's distance from the earth from 112 to 132 million miles during the month; it moves from a little north of ι Aquarii early in the month close to the constellation Pisces on December 21. Jupiter, an evening star, rises at 19h. 40m., 18h. 40m. and 17h. 25m. on December 1, 15 and 31, respectively. Its stellar magnitude, $-2\cdot1$ during most of the month, becomes $-2\cdot2$ towards the end, the increase in brightness being due to the planet's decrease in distance from the earth by 23 million miles; careful observation will show the westward movement in Cancer. Saturn, a morning star, rises at 5h. 30m., 4h. 45m. and 3h. 50m. on December 1, 15 and 31, respectively; it has a slow movement from α towards ν Librae, and this can be easily detected by careful observation. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Dec. 11d. 05h. 19·4m., μ Gemi. (*D*); Dec. 11d. 06h. 0·8m., μ Gemi. (*R*); Dec. 12d. 04h. 16·9m., 56 Gemi. (*R*). (*D* and *R* refer to disappearance and reappearance, respectively.) The meteor shower during December 11–13, the Geminids, which attains its maximum about this time, will not be easily observed owing to moonlight. An annular eclipse of the moon on December 25, invisible at Greenwich, will be visible in South Africa and the southern Indian Ocean. Winter solstice occurs on Dec. 22d. 09h.

Announcements

MR. J. R. WHINFIELD, a member of the Terylene Council of Imperial Chemical Industries, Ltd., at Harrogate, has been made an Honorary Fellow of the Textile Institute, in recognition of his outstanding contribution to the science and technology of man-made fibres. Mr. Whinfield is the twelfth recipient of this award.

THE American Documentation Institute has presented a scroll of appreciation to Dr. Atherton Seidell, one of the founders of the Institute, for his work in establishing microfilm services, which have been of particular value to documentation centres and libraries in general. Dr. Seidell founded in 1941 the *Current List of Medical Literature*. He is also noted for his development of an inexpensive viewer for short strips of microfilm and a microfilm projector.

THE Second Middleton Memorial Lecture will be given by Prof. K. Mather, professor of genetics in the University of Birmingham and director of the Agricultural Research Council's Unit of Biometrical Genetics, in the Senate House, University of London, on December 9, at 5.30 p.m. He will speak on "Fundamental Science in Agricultural Research, with Special Reference to the Development of Genetics". Admission is free, without ticket.

AN exhibition of scientific books and periodicals from The Netherlands will be opened at the Science Library, Imperial Institute Road, London, S.W.7, on December 1. The exhibition will remain open until December 22.

THE fifth annual meeting of the Société de Chimie Physique will be held in Paris during May 31–June 3, 1955, when the chemical actions of ionizing radiations on liquids will be discussed. Those wishing to read papers must send in the titles by December 15, 1954, and the full text by February 28, 1955, so that the papers can be printed in advance of the meeting. Further information can be obtained from the secretary-general of the Society, Prof. G. Emschwiller, École Supérieure de Physique et de Chimie, 10 rue Vauquelin, Paris 5^e.

THE Meldola Medal, which is the gift of the Society of Maccabaeans and is normally awarded annually, is being offered for early award in 1955 to the chemist who, being a British subject and less than thirty years old on December 31, 1954, shows the most promise, as indicated by published chemical work brought to the notice of the Council of the Royal Institute of Chemistry before December 31. Communications should be addressed to the President, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1, the envelope being marked "Meldola Medal".

SIR GEORGE BEILBY Memorial awards, which are considered at intervals by administrators representing the Royal Institute of Chemistry, the Society of Chemical Industry and the Institute of Metals, are made to British scientific research workers, preference being given to investigations relating to the special interests of Sir George Beilby, including problems connected with fuel economy, chemical engineering and metallurgy. The administrators request that their attention be directed, not later than December 31, to outstanding work of the nature indicated. All communications should be addressed to the Convenor of the Administrators, Sir George Beilby Memorial Fund, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1.

SCIENTIFIC CIVIL SERVICE

PROMOTION OF INDIVIDUAL RESEARCH WORKERS

SPECIAL posts have again been created this year in the Scientific Civil Service under provisions included in the White Paper (Cmd. 6679; 1945) designed to provide for the promotion of individual research workers of exceptional merit. The promotions are effective from July 1.

Deputy Chief Scientific Officers

Dr. S. K. Kon, who has been head of the Nutrition Department of the National Institute for Research in Dairying since 1937, has made extensive researches which have led him to be recognized both nationally and internationally as a leading authority in nutritional science. In particular, his work has covered the nutritive value of milk and milk products, methods of assay of vitamins (especially vitamin A and the B vitamins) and the synthesis of vitamins in the animal organism, and this and studies in several other fields of nutritional biochemistry have provided both new knowledge and valuable practical applications. He has been editor of the *Proceedings of the Nutrition Society* since the inception of that Society in 1944 and of the *British Journal of Nutrition* from its beginnings in 1947.

Dr. H. R. C. Pratt studied chemistry at Birkbeck College, London, and, later on, chemical engineering, his Ph.D. thesis in 1951 on "Studies in Azeotropic Distillation" being based on work done during the Second World War. He held research and development appointments in industry before joining the Atomic Energy Research Establishment, Harwell, in 1949 as leader of a group investigating chemical engineering operations of special interest to atomic energy. Dr. Pratt has himself made a significant contribution to liquid–liquid extraction and for one of his published papers he was awarded, with R. Murdoch, the Moulton Medal of the Institution of Chemical Engineers last year. He is also interested in the methods of production of heavy water, and his developments in water distillation techniques have brought this method into the realm of practical economics.

Senior Principal Scientific Officers

Dr. H. A. H. Boot graduated from the University of Birmingham in 1938 and later, during the Second World War, was co-inventor, with Dr. J. T. Randall, of the cavity magnetron which established and maintained for the Allies so great an advantage in the field of radar. During 1945–48 Dr. Boot held a senior Nuffield research fellowship at Birmingham and was engaged on the design of the cyclotron. He then joined the Royal Naval Scientific Service and since then has been mainly occupied at the Services Electronics Research Laboratory in research, development and design for the manufacture of advanced types of magnetron of very high power.

Mr. K. V. Diprose entered the Royal Aircraft Establishment in 1935 on leaving Cambridge, where he had read for the Mechanical Sciences Tripos, being awarded the J. B. Seeley Prize in Aeronautics. He has displayed outstanding scientific and design ability in several fields, including the instrumentation of wind tunnels, the aerodynamics of airscrews, early jet-engine research, analogue computing instruments and data-reduction schemes for wind tunnels. He is a leading British authority on analogue computers, and the present general recognition of the importance of a co-ordinated approach to the whole problem of the design of experiments, processing of data and computing of results, is due in large measure to his efforts during the past ten years.

Mr. T. M. Fry worked on underwater detection problems for the Admiralty during 1939–45, before proceeding to the University of Cambridge. After graduating in 1947, he joined the Atomic Energy Research Establishment, Harwell, where he investigated changes in the properties of graphite and other solids resulting from exposure to the radiations in nuclear reactors. As well as its importance for the development of nuclear power, this type of work provides a new method for investigating the solid state. Since 1951 he has devoted his attention mainly to a study of the fast-breeder reactor, and in addition, since 1947, he has been associated with Mr. F. T. Bacon's hydrogen–oxygen cell research at Cambridge.

Dr. E. R. R. Holmberg graduated from the University of Cambridge in 1939 and entered Admiralty service the following year. He was appointed to the Mine Design Department and during the next five years played a significant part in solving the many problems involved in ship demagnetization. In 1945 he was transferred to the Admiralty Gunnery Establishment, where his mathematical ability was directed to theoretical studies of missile guidance and control systems. Since 1950 he has been serving in the Department of Operational Research. In 1952 he was elected to the Geophysical Committee of the Royal Astronomical Society and has had a number of papers published in the *Monthly Notices* of the Society in which, as in his defence research work, he has shown a marked originality of outlook and incisiveness of method.

Dr. D. Kuchemann was engaged in aeronautical research at A.V.A. Gottingen with Prof. Betz after obtaining his doctorate at the University of Göttingen in 1936. He gained a considerable reputation there for his work on basic aerofoil theory, wind-tunnel corrections and the aerodynamics of propulsion. He joined the Royal Aircraft Establishment in 1946 in the Wind Tunnels Group, where he has made important contributions to research on swept wings and the flow about high-speed aircraft configurations, both from the theoretical and experimental aspects, which have led to a greatly improved understanding of the fundamentals of high-speed aircraft design.

Mr. S. W. Noble joined the Telecommunications Research Establishment, now the Radar Research Establishment, at Swanage in 1940, after varied industrial experience. He was engaged on research in the radar field until 1944, when he commenced work on advanced circuit research with which his name is now prominently associated. He has made outstanding and distinctive contributions to electronic circuit design, in which field he is an acknowledged leading authority.

Dr. F. Pasquill has been mainly engaged in problems of atmospheric diffusion and turbulence near the surface of the earth, since his appointment to the Meteorological Office in 1937. His association with the Chemical Defence Experimental Establishment, Porton, during his early years of service, was marked by a valuable experimental study of evaporation from a plane-free liquid surface into a turbulent air stream. Later, in charge of a small Meteorological Office group attached to the School of Agriculture, Cambridge, to study micro-meteorological problems with application to agriculture, he devised a method and equipment for the investigation (by the use of accurate vertical profile measurements of humidity and temperature) of the exchange of heat and water vapour between a grass-covered surface and the air immediately above. This led to a successful evaluation of evaporation from the surface. The aerodynamic drag of grassland was also investigated. Dr. Pasquill is now engaged in research on atmospheric diffusion processes on a more extended scale.

DR. J. M. SHEWAN studied chemistry in the University of Aberdeen, being awarded a medal in physical chemistry in 1932, and gained his Ph.D. for work at the Macaulay Soil Research Institute. He then entered on a career in marine bacteriology and biochemistry at the Torry Research Station, where his work has included the only really detailed study of the strict anaerobes of fish, a survey of the aerobic microflora of gadoids, and the discovery that the microflora of fish varies considerably with species, locality, time of year and method of catching. In the preservation of fish he has shown how the microflora changes in composition, as spoilage proceeds, and he has made pioneering studies of the effect of phenolic substances in wood smoke in the curing of smoked fish. He is at present engaged in unravelling the taxonomic confusion which exists in the field of marine bacteriology, and on an extensive study of the extractives of fish which are the substances first attacked by bacteria. In connexion with the preservation of fish on ice, he has developed a sensory scoring system which, as a research tool, has become of great use in defining and controlling standards of freshness.

MR. G. W. C. TAYLOR joined the Research Department, Woolwich Arsenal, in 1929, transferring to the staff of the Explosives Research and Development Establishment, Waltham Abbey, on its formation in 1945. His early experience was in the chemical analysis and testing of explosives, which was followed by photographic and radiological investigations. Since 1939 he has been concerned with a special class of explosives, carrying his researches from the laboratory stage to full-scale manufacture, and this has led to investigations on the control of crystallization which have given rise to practical results of the greatest value. Much of his work has been of a pioneering nature in a region hitherto unexplored because of the formidable hazards and difficulties involved.

MR. J. H. WILKINSON graduated in mathematics from the University of Cambridge and then worked on ballistics in the Ministry of Supply for some six years before joining, in 1946, the Mathematics Division of the National Physical Laboratory, Teddington. He has worked on the design and exploitation of high-speed automatic electronic digital computers, and has been very closely associated with the theoretical design, electronics and practical use of the Laboratory's machine, the Pilot ACE. In particular, he has made a very thorough study of practical methods of calculating latent roots and vectors of matrices, which are of wide application, especially in problems of aircraft design.

DR. H. G. WOLFHARD studied physics at the University of Göttingen, gaining his doctorate in 1938, and later joined L.F.A. Volkenrode, where he worked until 1946, taking charge of a group on combustion towards the end of this period. He joined the Royal Aircraft Establishment in the same year, where he has worked in the Chemistry Department and, more recently, in the Rocket Propulsion Department in charge of the combustion section. During 1946–52 he worked part-time with Dr. A. G. Gaydon at the Imperial College of Science and Technology, London. He has been outstandingly successful in the application of spectroscopy to the study of flames and combustion processes.

WORLD POWER RESOURCES

IN his presidential address given before the Institution of Electrical Engineers on October 7, Mr. J. Eccles was concerned mainly with the power resources of the world. He sketched in outline the origins of the earth's main resources of fuel, first tracing the exceedingly gradual evolution of man's use of mechanical power up to the opening of the industrial era. He then showed that, with the enormously accelerated rate of consumption of fuel which has developed during the past two hundred and fifty years, a further period of several hundred years will see the substantial exhaustion of the world's resources of coal and oil; indeed, the supply of oil fuel may well become critical during the lifetime of the present rising generation.

Dealing with other available forms of energy, apart from nuclear energy, Mr. Eccles first considered water power and tidal power. Some forty per cent of the world total of inland water power is located in Africa, and this total without, of course, regard to location, could supply at least three-quarters of the world's present energy requirements. He remarked that one of the largest and most spectacular sources of water power lies at the western end of the Mediterranean, for this inland sea loses water through evaporation at a rate exceeding its river inflow, so that water is constantly flowing through the Straits of Gibraltar and, to a lesser extent, through the Dardanelles. If both straits were dammed, the level of the Mediterranean would gradually fall, and rough calculation shows that, having established a differential of 70 ft., 12 million kW. (which is 75 per cent of the present demand for electricity in Great Britain) could be developed from suitable turbines operated by inflow from the Atlantic.

Summing up the position in regard to what may be termed the conventional sources of energy, Mr. Eccles said that, when coal and oil are exhausted, and in the absence of a successful outcome of the attempts to harness the nuclear fission or fusion process for industrial purposes, it should be possible to muster man's present-day energy requirements from all the known sources, but that energy transmission or population transportation would present enormous technical and social problems.

If the present pattern of civilization is to endure, the problems of nuclear energy must be mastered. It has been established, said Mr. Eccles, that, on the basis of present costs, an expenditure of about

£50 per pound of pure metal would be sufficient to mine and to refine sufficient uranium to provide the world's present energy requirements for some 1,500 years, or on a similar basis, an expenditure of £100 per pound could furnish these requirements for 8,500 years. The abundance of hydrogen in the earth's crust could provide almost unlimited power from the hydrogen–helium reaction, but the industrial application of this must await the discovery of means of enabling the reaction to proceed at a lower sustained temperature.

Because of the possibility of supplying the world demand for power by means of nuclear fission, it is now sometimes argued that all development effort should be applied in that direction and the development of other sources abandoned. Mr. Eccles, however, did not hold this view: when there is, for example, "a local surplus of water power, the energy could be used to purify fissile material so as to provide power in lands where the alternatives are insufficient. Since fissile material, even in its natural state, is easily transportable, such packaged fuel might solve the power transmission problem".

Finally, Mr. Eccles referred to the minute fraction of existence of the human race within which this tremendous demand for power has developed, and he emphasized the paramount necessity to match, by means of continued technological advancement, the world's progressive demands for the basic necessities of food and fuel. "In sum, therefore, man having evolved during a million years has, over the past 250 years, developed a mode of living which is unique in human history. This achievement has thus lasted for only 0·025 per cent of his sojourn here and already it has made great demand on the energy resources of our planet. Unless he is able and willing to match his technology to the unfolding needs of the situation, he has no prescriptive right to a continuance of this latest civilization, and the history of civilizations discloses that discontinuity—decay and rebirth—is the normal method by which successive stages have been reached. However, to-day man is equipped with a knowledge of natural laws (science) and an ability to harness these laws to his needs (engineering) that were absent in all previous civilizations, and there is good reason for thinking that the present mode of living can be greatly prolonged if he will but use this knowledge and ability aright."

AIRCRAFT ELECTRICAL SYSTEMS

A VACATION school on "Aircraft Electrical Systems" was held in the Electrical Engineering Department of the Imperial College of Science and Technology, London, during September 20–24 and was attended by nearly seventy engineers drawn from electrical and aircraft industries, research organizations and the College of Aeronautics, Cranfield. The purpose of the school was to bring out the scientific principles underlying the design and application of all forms of equipment used in aircraft electrical systems in relation to both present and future requirements. The course was very successful, particularly since those who participated contributed a large part to the discussions. The conclusions drawn were that more co-operation is needed between design and installation engineers and that, notwithstanding the special conditions of aircraft work, much can be learned from ordinary industrial practice; educational work was also stressed, particularly the part being played by Imperial College.

In his opening address, Sir Frederick Handley Page emphasized the importance of fundamental research in that it often leads ultimately to useful practical results. After directing attention to electrical and aeronautical engineering as the two newest branches of the art, he referred to the interesting problems which have arisen as they have progressively come together, and to the need for closer liaison between members of these two branches. In an introductory survey, D. F. Welch (British Thomson-Houston Co., Coventry) outlined the problems facing the aircraft electrical engineer. Since 1940 power requirements have risen from 1 kW. to 200 kW. for large aircraft, and with these powers the potentially destructive power of a fault has focused fresh attention on circuit protection. The avoidance of any breakdown is doubly important in that the introduction of power-operated controls and the electrical operation of essential flying instruments mean that the safety of an aircraft is now dependent on the maintenance of the electrical power supply. M. Hancock (Royal Aircraft Establishment, Farnborough), speaking on environmental conditions and functional requirements, pointed out that these lead to acute differences between aircraft and ground-based electrical engineering practice: operation at high altitude increases arcing problems in switchgear and decreases machine cooling, while the wide temperature-range over which the equipment must function increases insulation and lubrication problems. Mechanical problems, vibration, weight and bulk considerations are all factors with special problems in relation to aircraft. In the third lecture, J. H. Rea (Rotax, Ltd.) dealt with power systems, and discussed the factors which determine the choice of system, methods of load analysis which distinguish between 'safety' and 'comfort' loads, and methods of weight analysis which lead to the lightest installation capable of supplying the load. The place of the battery, with particular reference to the problem of engine starting, was also considered.

The more specialized lectures given at the course commenced with that of R. F. Sims (Farnborough), who first discussed the physical causes of the abnormal brushwear experienced at high altitudes, outlining remedial measures such as the use of special materials or the control of the moisture content of the machine-cooling air, and then in the second part of his lecture considered vibration problems. After a general survey of cooling problems, Dr. C. S. Hudson (Farnborough) reviewed the effects of radiation, natural and forced convection, and conduction, and discussed methods of calculating the pressure head required in a cooling system. The topic of d.c. machines was covered in the next lecture by B. Adkins (Imperial College, London), who showed how machines must be compactly constructed in order to obtain the output required with minimum weight. He also pointed out how the insulation, the methods of connecting and securing the windings, and the grease used for lubrication, all set a limit to the permissible temperature rise.

On September 22 the members of the course visited the works of Vickers-Armstrong, Ltd., at Weybridge, including the company's Electrical Laboratory and the Research Department, and the seventh lecture, on electrical installation engineering, by H. Zeffert (Vickers-Armstrong), was partly a commentary on the visit, for Dr. Zeffert described and demonstrated many types of plugs, sockets, terminal blocks and cables. The main run of lectures was continued on the next day with one on a.c. machines by W. Philipp (Rotax, Ltd.), who discussed the problems of alternator design, both for the long speed-range machines now in use and for the constant-speed machines which will be required when a constant-speed drive, taken either from an engine-driven hydraulic gear or from a separate turbine, becomes available; he also spoke on conversion equipment, using invertors, rotary transformer or motor-alternators, and on induction motors. From machines the programme of the course turned to system operation and protection, in which K. J. Payne (British Thomson-Houston Co., Coventry) considered power system maintenance, servicing the system or correcting faults being, of course, impossible during actual operational use. After a general discussion on the limits of operation of the components of a typical system and their effects on system performance, and also protection techniques, Mr. Payne described the transient behaviour of inverters and motors and the effects of electrical and mechanical shock loads. The theme of A. Grieve's (British Thomson-Houston Co., Coventry) lecture was switchgear, the factors involved in the design of switches, and the limitations imposed on performance by the fundamental properties of the materials and of the environment in which they are to operate; in discussing the characteristics required of a circuit breaker, he said that protection against most forms of fault can be incorporated in any unit of switchgear.

In the concluding survey, in which he discussed future trends, S. F. Follett (Ministry of Supply) stated that future aircraft will fly faster and higher, so that environmental changes will most influence future practice; he felt that the need for reliability should be stressed, and that reliability should be proved on life-tests which approximate to aircraft conditions and allow for the effect of vibration.

MARINE BIOLOGY IN LATIN AMERICA

During September 15–17 a group of Latin American specialists in marine biology met in Concepción (Chile) in order to study the possibility of establishing an international network of marine biological laboratories in Latin America and other ways of facilitating the collaboration in this field among the Latin American countries. The meeting was convoked by the Unesco Science Co-operation Office for Latin America and was a sequel to the recommendations for setting up international and regional laboratories made at a meeting held in Montevideo in 1952 upon the initiative of the Unesco Office (see *Nature*, 170, 605; 1952). The scientists attending the meeting were from the Argentine, Brazil, Chile, Cuba, Mexico, Peru, Venezuela and Uruguay. The Regional Office in Santiago de Chile of the United Nations Food and Agriculture Organization collaborated in arranging the meeting.

After studying the present situation of research in marine biology in Latin America and its future possibilities, the delegates entered on an extensive discussion about the possibilities and ways of establishing an international network of laboratories. It was unanimously decided to create immediately under the auspices of the Unesco Science Co-operation Office a Latin American Committee in order to co-ordinate and facilitate the research work in marine biology. The Committee would remain in office until a permanent organization had been set up. The meeting requested the Unesco Office to prepare a draft convention for an international network of laboratories and convoke a meeting of official delegates in order to establish the corresponding organization.

The meeting also studied what other steps could be taken immediately pending the realization of the more far-reaching recommendations, in order to promote research in marine biology, and advised the Unesco Office that two training-courses on the methodology of marine biology research and a symposium on plankton should be organized in 1955. It was also recommended that the *Marine Biology Journal*, produced by the Montemar Station in Chile, should be widened in scope with a Latin American editorial board.

The Brazilian representatives to the meeting have been duly authorized by the Governor of the State of São Paulo to put at the disposal of the Unesco Science Co-operation Office for international research work the complete network of marine biological laboratories and stations and research vessels of the State of São Paulo. This offer will make it possible to initiate shortly international research and training programmes in marine biology under the auspices of the Unesco Office.

UNITED NATIONS ORGANIZATION

ANNUAL REPORT OF THE SECRETARY-GENERAL FOR 1953–54

The ninth annual report of the Secretary-General of the United Nations to the Member States on the work of the Organization during July 1, 1953–June 30, 1954* is not an encouraging document. It gives a picture of diversity of effort which closely matches that to be found in the reports on the work of the League of Nations, and, as with that organization, it is in the technical fields that progress is most marked. Elsewhere, and above all in the political field, the gap between purpose and achievement is wide; nor does it appear that all Member States are concerned to advance the declared purposes of the United Nations. The Secretary-General comments on the need for a careful balance in the development of regional arrangements outside the framework of the United Nations. Choice of such arrangements for the maintenance of peace should not be permitted to cast doubt on the ultimate responsibility of the United Nations, or to impair the right of a Member State to a hearing under the Charter.

Referring to the lack of progress in disarmament, the Secretary-General comments on the potentialities of the development of an international partnership, open to all nations, in the use of atomic energy for peaceful purposes, especially for the economically under-developed areas of the world. Apart from recording President Eisenhower's statement of December 8, 1953, the report makes no other reference to the use of atomic energy for peaceful purposes. The report also puts on record the opinion of the United Nations Commission on the racial situation in the Union of South Africa that the doctrine of racial superiority, on which the apartheid policy is based, is scientifically false, extremely dangerous to internal peace and international relations, and contrary to the dignity and worth of the human person; but the report is so careful to give both sides of the case, and to avoid giving offence, that it presents a picture of frustration which, while it may exceed the reality, completely bewilders the ordinary reader.

---

* United Nations. Annual Report of the Secretary-General on the Work of the Organization, 1 July 1953–30 June 1954. (General Assembly—Official Records: Ninth Session. Supplement No. 1 (A/2663).) Pp. xv+120. (New York: United Nations; London: H.M.S.O., 1954.) 1.25 dollars; 9s.; 5 Swiss francs.

It is a relief to turn to the chapters of the report which deal with economic and social questions where, by and large, the United Nations is carrying on so much that was begun under the auspices of the League of Nations. In the field of narcotic drugs, 6-methyl-Δ-6-deoxymorphine and its salts and five synthetic narcotic drugs have been brought under control, and a new list of factories manufacturing narcotics has been completed on the basis of information supplied by governments and will be published shortly. A programme of studies on the cultivation and wild growth of the cannabis (Indian hemp) plant, the production, licit and illicit distribution and consumption of drugs from it and their control has been approved, and papers on synthetic substances with morphine-like effects and on addiction-producing effects in relation to chemical structure have been prepared, while a programme of scientific research on opium continues to be pursued.

On the Expanded Programme of Technical Assistance for the economic development of under-developed countries, the report adds little to recent reports (see *Nature*, November 20, p. 960). Reference is made to the easing of financial management which resulted from the holding of the pledging conference before the beginning of the year, but financial resources are still inadequate to meet all the requests received. Of the 23·5 million dollars earmarked for expenditure in 1953, 18·1 per cent was for health services and 7·7 per cent for educational purposes, including research. For 1954, 75 per cent of total resources, excluding carry-overs, will be automatically available for allocation to the participating organizations, but the system of allocation for future years is under review. Commenting on the regular programme of technical assistance, the report notes that technical assistance has become an accepted means of international co-operation and has been instrumental in changing the climate of opinion in international affairs. More intensive use of its possibilities has been assisted by a better-defined conception of technical assistance in most recipient countries, and in a measure the success of technical assistance projects is indicated by the increase in their average duration. In discussing the development of public understanding generally, the Secretary-General suggests that the Technical Assistance Programme has been an important factor in the growth of public understanding at least of the non-political work of the United Nations during the past twelve months. It is clear that much remains to be done, though the means by which such educational work is best effected calls for further discussion than is possible in the present report. There are some sound comments on the role of the Secretariat; but while the Secretary-General rightly insists that there are limits to the work which can be entrusted efficiently and effectively to a Secretariat of any given size, and even to the amount of work which can usefully be undertaken by an international organization not circumscribed by such limits, his references to the question of staff loyalty and independence on which the smooth functioning of an international civil service fundamentally depends are purely factual and fail to bring out what is at stake.

ORIGINS OF THE INTERNATIONAL COUNCIL OF SCIENTIFIC UNIONS

In the 1954 Year Book of the International Council of Scientific Unions*, the secretary-general, Prof. A. V. Hill, contributes a valuable account of the origins of the Council. In the latter part of the nineteenth century a number of international scientific organizations were started. Some were to advance science by direct co-operation. Others were to facilitate personal acquaintance and interchange of opinion; international scientific congresses held periodically are in this class. Others aimed at establishing uniformity of standards of measurement, and of these the earliest was the Bureau International des Poids et Mesures, which was established at Sèvres in 1873 as the outcome of an international commission set up in 1869 for the construction of metric standards.

For some years before 1898 the Academies of Munich and Vienna, with the Royal Societies of Gottingen and Leipzig, had met annually as an association to discuss matters of common interest. In 1898 the meeting was to be held in Göttingen, and the Royal Society of Gottingen invited the Royal Society of London to take part; the latter agreed to join the association if its scope was so extended as to assume a fully international character. In 1918 the Royal Society, the Academy of Sciences in France and the National Academy of Sciences in the United States discussed informally the future organization of scientific undertakings which had been carried on before the First World War by international co-operation; ultimately the academies of all the Allied countries were invited to send representatives to a conference which took place in London in October 1918. This was followed by a meeting in Paris a month later, when an executive committee was appointed to draft the statutes for an International Research Council which, with a number of affiliated International Unions, might deal with matters of international scientific interest. A General Assembly of this Council was held at Brussels in July 1919, when the statutes of the Council were approved. International Unions for Astronomy, Geodesy and Geophysics, Chemistry and (shortly after) Mathematics were formed: and to these were later added Scientific Radio, Physics, Geography, Biological Sciences, Crystallography, Theoretical and Applied Mechanics, History of Science, and Mathematics (reconstituted in 1952).

At the start, the International Research Council retained control over the Unions and only allowed countries to join the Unions which already adhered to the International Research Council. Differences of opinion about this and other matters led to a reorganization in 1931, by which the Council was transformed into the International Council of Scientific Unions. Under the new arrangement the Unions became autonomous within the framework of the new Council, the General Assembly was permitted to meet elsewhere than in Brussels, and adherence of a country to any Union no longer required adherence to the Council.

---

* The Year Book of the International Council of Scientific Unions, 1954. Pp. ii+82. (London: International Council of Scientific Unions, c/o Royal Society, 1954.)

In 1946 the United Nations Educational, Scientific and Cultural Organization (Unesco) was formed and a formal and mutual draft agreement between Unesco and the International Council of Scientific Unions was approved by the Council in 1946 at its first General Assembly after the Second World War. This agreement was modified in 1947 and again in 1952. The present agreement is described in the year book of the Council, which also contains details of members of the various councils, statutes and rules, the activities of the Council and the state of its finances.

WEIGHING IN THE LABORATORY

The principles of the design, adjustment, use and testing of good-quality knife-edge balances and weights employed for precise weighing in scientific laboratories forms the subject of the seventh in the series of "Notes on Applied Science" issued by the Department of Scientific Research*. The information given, which is based largely on the experience gained at the National Physical Laboratory, Teddington, in maintaining the standards of mass and in testing weights and balances, should be of great value to those in industry and research who are concerned with precise weighings.

The contents, which are in two parts dealing respectively with knife-edge balances and weights, are much more detailed than in previous numbers of the series and include illustrations of the precision 1-kgm. balance at the National Physical Laboratory which is used for the comparison of national standards of mass, of the Imperial Standard Pound and the British National Copy of the International Kilogramme, and several tables and three appendixes. In Part 1 the chief features—functioning and adjustment of the simple equal-arm balance—are outlined clearly and fully with particular emphasis on the essential practical requirements. Various types of balance are discussed, and comparative information is summarized in two useful tables. The methods and technique of weighing are described, and net buoyancy corrections to obtain mass from weighings in air, and values of the density of air for the ranges 5–30° C. and 600–800 mm. of mercury are tabulated. A clear distinction is drawn between the conceptions of sensitivity and accuracy of performance of a balance, and a guide is given to the varieties of balances readily available.

In Part 2 the suitability of the various materials used for the construction of weights is considered first. Plain polished brass is unsatisfactory; and, of the coating materials, lacquer is too hygroscopic, uncoated nickel plating fogs and gold plating is often porous and is also liable to loss of weight due to wear. The construction, adjustment and tolerances are discussed next, followed by a brief description of the tests and methods of verification of weights carried out at the National Physical Laboratory, which will be of considerable interest to those who are contemplating sending weights for test at the Laboratory or who intend to carry out their own tests.

In the three appendixes, the simple fundamental analysis of the equal-arm undamped knife-edge balance substantially as given in Glazebrook's "Dictionary of Applied Physics", the mathematical discussion of the motion of the damped beam, and the effect of air-buoyancy on a single-pan balance are given separate treatment.

AGES OF URANINITES BY A NEW METHOD

By Dr. B. WASSERSTEIN
Geological Survey, Pretoria

In a previous communication in *Nature*[1], I suggested that the generation by radioactive decay of smaller atoms of tetravalent lead within the crystal lattice of uraninites caused a shrinkage in the unit cell proportionate to time; some preliminary results were given in a table. Using artificial uranium oxide (UO_2) as an end-point to denote zero time, four results clearly supported the thesis; but three others, agreeing well among themselves, were apparently too high and in conflict. Further work has indicated an obvious solution, namely, that there are, in fact, two different types of uraninites involved: those agreeing with the thesis I call α-uraninites and are considered normal; those which are apparently anomalous are called γ-uraninites.

The pitchblendes are classified as β-uraninites. As their spectra are usually too poor for accurate measurement, they are for the moment disregarded for age determination. Present work indicates that they are abnormally high in oxygen; this excess can be removed by heating in hydrogen to give cube-edges comparable with α-uraninites for purposes of age determinations; these results will be shortly announced.

The characteristic feature of γ-uraninites is that their cube-edges are reduced on heating in air to correspond to that of an α-type analogue, whereas α-uraninites upon similar treatment disintegrate to give an X-ray pattern of U_3O_8. This phenomenon was first detected in two analysed samples, previously given as from Namaqualand, but more accurately, from the Gordonia district, South Africa[1]. In presenting the data, a thoria correction—also discussed previously—has to be applied, and this is −0·0013 A. for each per cent ThO_2 when $ThO_2 + UO_2$ total 100 per cent—this suffices for a first approximation. The thoria content differs slightly in the two samples, which gave the following results:

	Gordonia	
	(Holmes) γ-type	(Mountain) α-type
Untreated	5·485 A.	5·444 A.
Corrected for ThO_2	5·462 A.	5·428 A.
Heated	5·450 A.	(disintegrates)
Corrected for ThO_2	5·427 A.	

The agreement now in the cube-edges derived from Holmes's heated sample, namely, 5·427 A., and Mountain's untreated one, which is 5·428 A., is remarkable—but not unique: similar results have been encountered from Brazil and Norway:

Boqueirao, Brazil (*ex* Harvard Coll.); untreated	5·481 A. (γ-type)
As above after calcination	5·449 A.
Same locality (*ex* Marble); untreated	5·445 A. (α-type)
Moss, Norway; untreated	5·488 A. (γ-type)
As above after calcination	5·449 A.
Saterdalen, Norway; untreated	5·450 A. (α-type)

The results agree within the limits of error in the determinations.

When γ-types are weathered, commercial nitrogen, which contains a little oxygen, serves to reduce the cube-edge and to differentiate between α- and γ-types; β-types are recognized by an increase in cube-edge when heated in hydrogen. These manipulations are necessary when the chemical differences of the three types of uraninites become apparent.

It is clear that each of the three types forms its own series showing shrinkage with time. The X-ray examinations of numerous uraninites, before and after heating, support this supposition; but the lack of accurate age determinations is a handicap in checking such results. In developing the present X-ray method, it is found preferable in practice to use results from heated γ-uraninites together with untreated α-uraninites, as generally the α-type is concentrated in the lower ages.

This classification of uraninites into three types can be deduced from certain laboratory studies of the uranium oxides, although total agreement among investigators may not have been reached. The relevant data have been largely assembled by Katz and Rabinowitch in their comprehensive text-book[2]. In dealing with the range $UO_{1\cdot75-2\cdot3}$, Zachariasen[3], Jolibois[4] and Alberman and Anderson[5] have made valuable contributions.

Jolibois provides evidence for the possible compound $UO_{2\cdot33}$ which he "... interpreted ... as a new uranium oxide U_3O_7 (or $UO_3.2UO_2$)"[2], and Alberman and Anderson prepared "... two well defined cubic phases, viz. UO_2 and a phase of composition close to $UO_{2\cdot3}$ ('β-UO_2 phase')"; further oxygenation gave them a tetragonal phase. At the other extreme, "Zachariasen found a homogeneous face-centered cubic phase with a composition of approximately $UO_{1\cdot75}$ (or U_4O_7, tetrauranium heptoxide) ... U_4O_7 may be a separate compound analogous to Th_4S_7"[2]. There is therefore considerable evidence for three oxides of uranium in the range discussed here, and these three are characterized by a fluorite structure with different parameters, namely:

$UO_{1\cdot75}$ (possibly U_4O_7)	5·488 A.
UO_2	5·470 A.
$UO_{2\cdot33}$ (possibly U_3O_7)	5·440 A.

(A confusion of A. with kX-units seems to exist in the data presented by Katz and Rabinowitch.)

Uraninites are thought to fall in the range given above, and the analogy in the laboratory is suggested to account for the threefold classification of the uraninites in this way:

γ-uraninites correspond to U_4O_7 ('γ-UO_2' ?)
α-uraninites correspond to UO_2
β-uraninites correspond to U_3O_7 ('β-UO_2').

With this classification and the thesis of tetravalent lead generation, a fine order can be brought into the apparently chaotic data on cube-edges. My investigations over a period of years on uraninites support this classification in several respects. All uraninites, after allowance for thoria, have cube-edges less than 5·488 A., and this indicates that no uraninite lies in the range $UO_{1-1\cdot75}$—where also no laboratory product exists. Three separate age-series can be recognized corresponding to the three oxides given above, using their cube-edges as criteria; and in these all α-uraninites, and all but possibly one β-uraninite, have cube-edges less than 5·470 A. and 5·440 A. respectively. As suggested in the classification, γ-uraninites require oxidation, whereas β-uraninites require reduction in order to compare their cube-edges directly with those of α-types.

Differential thermal analysis evidence was obtained upon my suggestion: an α-uraninite (Rhokana Mine) differed from a γ-uraninite (Gordonia). The latter showed a gentle exothermic curve[6] which is in harmony with oxidation of $UO_{1\cdot75}$ to UO_2.

X-ray studies of thorianites are also illuminating, as here no hexavalent state of thorium can contribute to the shrinkage of the unit cell. All thorianites belong to the γ-type and therefore suggest, in analogy to U_4O_7, the oxide Th_4O_7. Although this oxide is apparently not yet known, Th_4S_7 has been prepared and suggests its possibility. In that event thorianites may well be regarded as the equivalent of Th_4O_7 rather than ThO_2.

The amazing coincidence that three compounds closely related chemically should at the same time yield almost identical X-ray patterns has prevented the recognition of the close parallel in Nature where analogous differences exist in the uraninites. Many chemical and mineralogical differences now find a more ready explanation.

Table 1

Sample	Type	Isotope age	Cube-edge (corrected for thoria)
UO_2	α	Zero	5·470 A.
Connecticut, U.S.A.	α	250 m.y.	5·463 A.
Belgian Congo	α	620 „	5·448 A.
Bisundni, India	α	735 „	5·443 A.
Gaya, India	γ	955 ± 40 m.y.	5·436 A.
Wilberforce, Canada	γ	1,035 „	5·432 A.
Gordonia, S. Africa (Mountain)	α	1,025 „	5·428 A
Gordonia, S. Africa (Holmes)	γ	1,025 „	5·427 A.
Witwatersrand, S. Africa	γ	2,000 „ (ref. 7)	5·400 A

The previously published table has been amended and corrected to give the results in Table 1, to which for the sake of interest and completeness the Witwatersrand value has been added to show the continuation of the shrinkage with time up to 2,000 million years. [Aug. 27.

ESTIMATES OF AGE FOR SOME AFRICAN MINERALS

By Prof. J. T. WILSON, R. M. FARQUHAR, P. GRETENER, R. D. RUSSELL and H. A. SHILLIBEER

Geophysics Laboratory, University of Toronto, Ontario

ABOUT two hundred radiogenic and ore leads from Canadian Precambrian minerals and a few potassium-bearing feldspars and micas have been analysed and dated at the University of Toronto. The results have been published[1–3] or are in the press[4]. Intercomparisons are being made with other laboratories[5]. These and other earlier age determinations have led to new interpretations of the structure of the Canadian Shield[6–11].

To test these conclusions for other continents, forty-five African minerals and a few from other continents have been analysed. The results for Africa are given here so that they can be compared with African geology by those acquainted with its details. These ages appear to agree well with those for uranium, thorium and lead minerals from Africa already published by Nier[12,13], Holmes[14–17], Ehrenberg[18] and Geiss[19]; but their relation to the results of Wasserstein[20] and Davidson[21] need further investigation. The rubidium–strontium method of age determination still appears to be in a state of development[22–24].

Our experience suggests that the following general conclusions about age determinations and continental structure may be tenable.

(*a*) We agree with Nier and Holmes that the ages obtained for uranium minerals are the most reliable when concordant ages are obtained by both chemical and isotopic analyses. This is the case for the monazite from Bikita, Southern Rhodesia[17]. Such results and preliminary measurements by R. D. Russell (unpublished results) suggest that radon loss does not appreciably affect age determinations by the lead ratio (^{207}Pb/^{206}Pb) method for old, fresh, uranium minerals, although it can lead to large errors in age determinations for young and altered minerals.

(*b*) Ages calculated from the argon–potassium ratio (^{40}A/^{40}K) for potassium-bearing feldspars and micas are in agreement with those obtained by the above methods. A value of 0·089 for the branching ratio of potassium-40 has been used to calculate the argon–potassium ages. This branching ratio was obtained by using radiogenic argon measurements carried out independently at two different laboratories[25,26].

(*c*) Isotopic analyses of many old lead ores can be used to date them[2,27]. The ages agree with those determined for apparently contemporaneous uranium and thorium minerals. It is considered that this method can be made still more precise, and that the curves used for dating them[27] may be modified. The ages given in Table 1 are therefore tentative.

(*d*) Vein minerals, including galena, give only minimum ages, and, unlike pegmatites, may be very much younger than the surrounding country rocks.

(*e*) All minerals more than about 2 × 10^9 years old have been found to come from areas underlain by rocks of Keewatin and Timiskaming types and by granites cutting them. Such areas are already known and dated in or around Ontario; Yellowknife, North West Territories; Uganda–Kenya; Southern Rhodesia; Transvaal–Swaziland; Sierra Leone; North Belgium Congo; Mysore, India; Kalgoorlie, Australia, and perhaps in the Sveco-Fennidian area. They are regarded as continental nuclei. They have a different type of structure and petrology from later belts, a higher proportion of lavas, and they may have been formed when temperatures in the earth were higher than in more recent times.

(*f*) All Archean-type rocks younger than about 2 × 10^9 years old form belts, each of which is marked by pegmatites formed during a limited range in time; they are markedly gneissic; they do not

* These ratios indicate ages younger than 800 million years which cannot at present be precisely dated by this method.

† The lead-208/lead-204 ratio for No. 28 indicates an age between 1,500 and 2,000 million years, but since it appears that radiogenic lead-206 and lead-207 have been added in anomalous amounts to it and in much larger amounts to No. 33, this age cannot be regarded as certain.

Six other isotopic analyses of radiogenic leads from Shinkolobwe have already been published by us (refs. 2, 32). The range of ages, 612–655 × 10⁶ years, agrees with Nier's results. These age values have been calculated using the constants:
$(^{238}U) = 0·153(7) \times 10^{9}$ yr.$^{-1}$, $(^{235}U) = 0·972(2) \times 10^{9}$ yr.$^{-1}$; $^{238}U/^{235}U = 137·8$.

contain a high proportion of lavas and they resemble the cores of young primary mountains. The Mozambique belt is an example (0·5–0·7 × 10⁹ years old). These gneissic provinces and young mountains both form broad belts lying beside or between continental nuclei and become progressively younger at greater distances from the nuclei (for example, Keewatin nucleus, Grenville gneissic belt and Appalachian Mountains of eastern North America).

(*g*) We agree with Leith[28], who recommended that the names Archean and Proterozoic should be used for "types of rocks not time", for we find that the maximum known age of some belts of Archean gneisses is much less than the minimum age of some Proterozoic-type rocks in other places. For example, the Archean-type Grenville belt contains many pegmatites all much younger (0·8–1·1 × 10⁹ years) than the veins which cut the flat-lying Proterozoic-type rocks at Martin Lake, Saskatchewan (1·6 × 10⁹ years). There seem to be similar circumstances in Africa.

(*h*) It is considered that the sialic blocks of the continents have been built entirely in geological time, for even the present rate of extrusion of lava, which has been estimated[29] to be 1 km.³ per year, would have sufficed to build the continents in about 4 × 10⁹ years. The work of MacGregor[30] and of Ewing[31] in the West Indies shows that the lavas there are predominantly acid and are rising from the depths through a basaltic ocean floor to form new additions of continental composition at the earth's surface. This appears to be the commonest type of volcanic process.

We wish to thank the geologists named for supplying the specimens and for their advice and interest. F. Dixey, A. Holmes, J. D. Louw, B. F. J. Schonland and E. S. Willbourn have also been very helpful. Additional samples to yield at least 15 mgm. of lead or consisting of a few hundred grams of potassium-bearing minerals would be welcomed.

Grants from the National Research Council of Canada and the Geological Survey of Canada, the Research Council of Ontario and Imperial Oil, Ltd., assisted this work. J. T. Wilson wishes to thank the Bernard Price Institute for Geophysical Research and the Carnegie Corporation of New York for the opportunity of visiting Africa. [June 15.

The Positive Column of High- and Low-Current Arcs

TRANSITIONS from a diffuse to a concentrated positive column have been observed to occur in electrical discharges in hydrogen as the current is increased[1], and a similar transition occurs from the 'low-current' to the 'high-current' carbon arc in air[2a-d]. As a result of a wide investigation of arcs in these and other gases, a purely thermal theory of these transitions has been developed, in contrast to the suggested explanation based on the magnetic pinch effect[2a,3]. A development and numerical integration of the equation of energy balance for the positive column of the arc after the manner of Brinkman[4] has enabled the radial temperature distribution for different central temperatures, and the variation of central temperature with current, to be calculated. In this the characteristic relationship between the temperature and the thermal conductivity, including the contributions of the classical kinetic theory and of the diffusion of ionized and dissociated pairs, which has been studied by a number of authors[2b,4-6], is of paramount importance. The data for nitrogen are illustrated in Fig. 1. The two maxima of the thermal conductivity at about 7,000° K. and 14,000° K. result from the dissociation and ionization of the gas respectively. In diatomic gases, the 'low-current' arc exists with central temperatures corresponding to the positive slope to the first maximum of the thermal conductivity–temperature curve, and the development of the concentrated core of the 'high-current' arc occurs in the region of negative slope, that is, between 7,000° and 9,000° K., for the arc in air or nitrogen.

The two relationships referred to above are both very similar for air and nitrogen at temperatures above 5,500° K., but have only been completely calculated for arcs in nitrogen. Figs. 2 and 3 show that good agreement between theory and observation is obtained in both cases, if Gaydon's value[7] of 9·76 eV. is adopted for the dissociation potential of N_2; the previously accepted value of 7·46 eV. does not show this agreement, and in the past has led to mistaken views as to the nature of the phenomena.

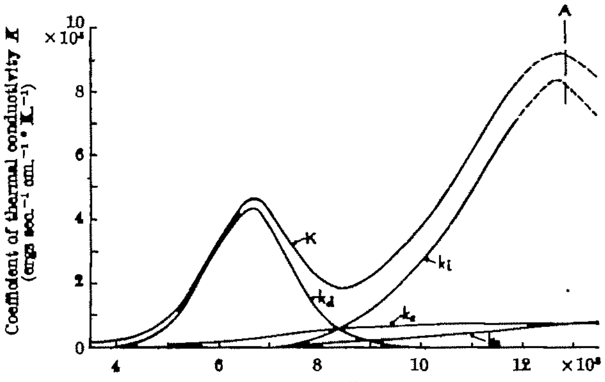

Fig 1. Variation of thermal conductivity of nitrogen, with temperature: k_a, classical conductivity of atoms and molecules; k_e, contribution of free electrons; k_i, contribution from diffusion of ionized pairs; k_d, contribution from diffusion of dissociated pairs; $K = k_a + k_e + k_d + k_i$

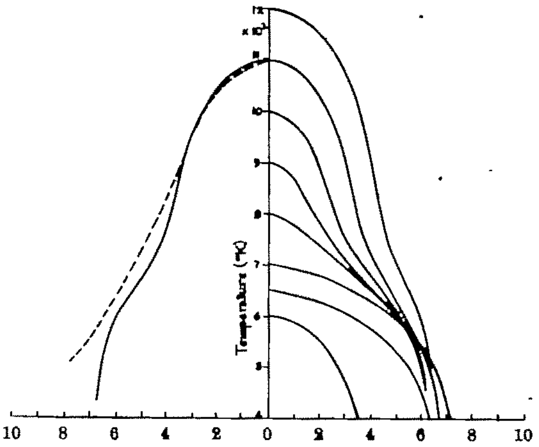

Fig. 2. Radial temperature distribution in arcs: ———, calculated (nitrogen); — — —, experimental, Maecker (air, ref. 8)

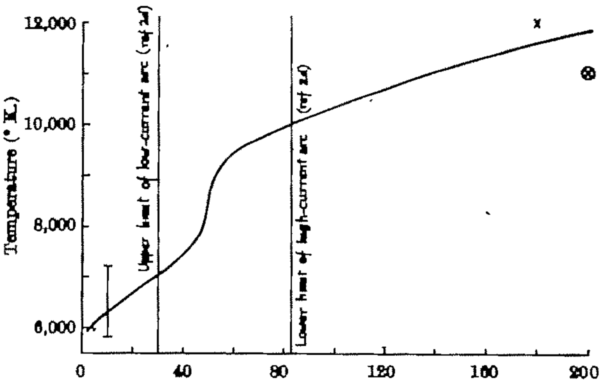

Fig. 3. Variation of central temperature with current for arcs in nitrogen. ×, Ornstein (ref. 9); ⊗, Maecker (ref. 8). Range of observed values for low-current arcs in air is indicated by vertical line on the left

Finkelnburg has suggested[2d] that the upper limit of the 'low-current' arc and the lower limit of the 'high-current' arc are about 7,000° and 10,000° K., respectively, and these values will be seen from Fig. 3 to be in general agreement with the present theory, the transition coinciding with the rapid increase in central temperature between 7,000° and 9,500° K. As regards the current at which the transition occurs, spectroscopic examination of carbon arcs in air in these laboratories showed that at about 50 amp. a narrow central core is formed emitting atomic lines and a continuous background. Though higher values are usually quoted for this transition current for the carbon arc in air, these refer to arcs between cored carbons. The positive column of these arcs contains impurities of low ionization potential which lower the arc temperature, so that the critical transition temperature is only reached at a higher current.

After the transition, the central temperature of the 'high-current' arc increases with current up to the second maximum in the thermal conductivity–temperature curve, which is caused by the increase of thermal conductivity with increase in the fraction of the gas which is ionized; when a temperature of about 14,000° K. is reached a second, inner, core is developed during the succeeding negative slope of the curve, from point *A*, Fig. 1, onwards. It is suggested that this second 'ionization' core will account for the observations by Guillery and Zill and by Beck of the "supercontracted arc stream" referred to by Finkelnburg[2d].

I wish to acknowledge my indebtedness to Dr. C. E. R. Bruce for instigating this study and to F. Goatcher for general assistance throughout, and to the director of the British Electrical and Allied Industries Research Association, Dr. S. Whitehead, for permission to publish this communication.

Resistance to Flow of Liquids over Solids by Thin Films extending from the Edge of Pools or from Menisci

In an investigation on the rate of spreading of liquids, including lubricants, (*a*) as a pool over horizontal surfaces, (*b*) between approaching and receding parallel flats, and (*c*) through capillaries, an unexpected resistance, associated with thin films extending beyond the boundary of the pools or from the menisci, has been measured in each kind of experiment. The angles of contact of water, benzene, *n*-hexane, etc., were small or zero, especially on surfaces wet with the respective liquids, and the large differences between the observed and calculated rates of movement in capillary ascent and fall could not be explained by the usual contact-angle hypothesis using the horizontal component $\gamma \cos \theta$ instead of γ, where γ is the surface tension and θ the angle of contact. Graphs relating the rate of radial spread over a horizontal surface of a pool of liquid with the height or square of the height of the pool were found to be curvilinear with an intercept on the force axis[1]. Similarly, a graph relating the rate of movement of an index of liquid in a precision capillary tube and the force acting was found to be curvilinear even with a liquid such as *n*-heptane[2]. In Fig. 1 is shown such a graph for benzene in a scrupulously clean dry tube. The dotted-line portion of the graph was for slow movement which was non-Newtonian, the index of benzene ascending a tilted tube (indicated on the graph by a negative force) or passing along a horizontal tube spontaneously. When the tube was tilted down slightly from the horizontal, the rate of movement for small forces remained non-Newtonian and was reversible, the index recoiling when the tube was placed horizontally after movement. More regular movement occurred with forces greater than three dynes, but the rate was considerably less than that calculated from Poiseuille's equation of flow. The predicted rate corrected for flow reversal at the menisci is shown by the broken line.

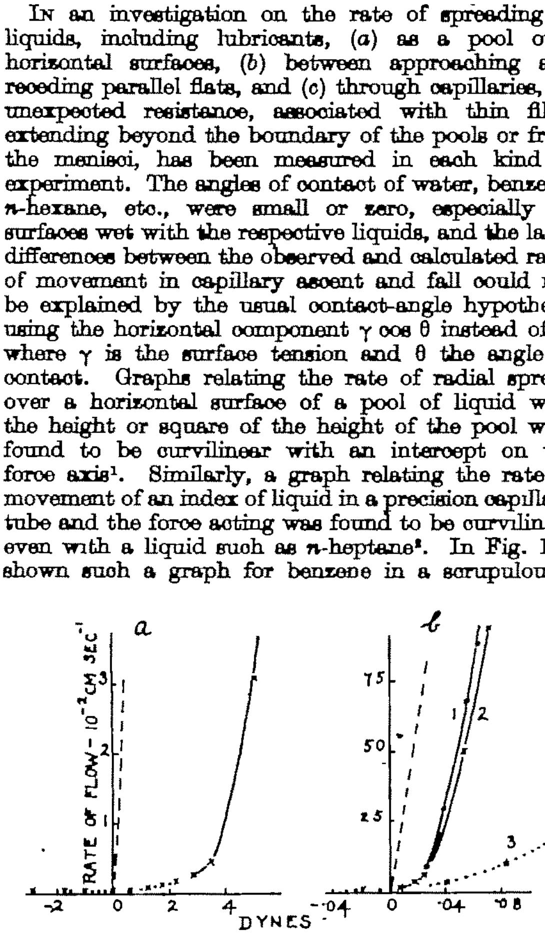

Fig 1. Relation between rate of flow in a capillary, 1 mm. diameter, and force acting: (*a*) benzene; (*b*) 1, *n*-hexane; 2, *iso*-octane; 3 toluene. Rate of flow in units of 10^{-4} cm. sec.$^{-1}$

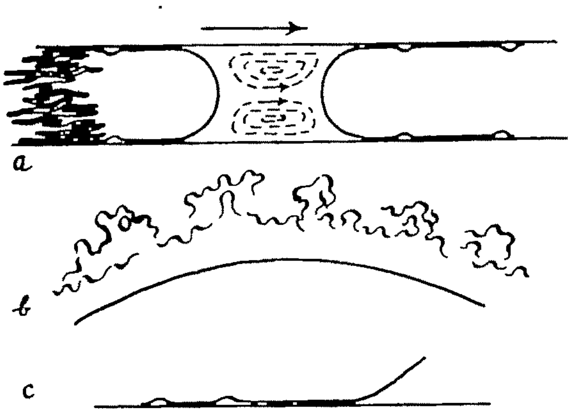

Fig. 2. Thin films adjacent to liquid menisci and pools. (*a*) Benzene index moving slowly in a wetted capillary showing filiform edging of rear thin film (rotation of liquid in index is shown by broken lines). (*b*) Edge of a drop of liquid (after Hirtz and Bernard, ref. 5), and (*c*) side view, indicating the thin film ending in a small ridge of liquid

A similar behaviour can be found with an air bubble moving in a tube filled with liquid. The contact angles appear to be zero, but the top meniscus is flattened and the bottom extended, while the graph relating force acting and rate of movement indicates non-Newtonian movement.

In a dry tube ahead of the advancing meniscus of a column, say, of *n*-heptane, it is possible to see interference colours due to the deposition of a film of heptane, while with water the formation of droplets ahead of the meniscus can be seen under the microscope. Migration of liquid molecules from the liquid front (primary creep) together with vapour deposition is responsible for the presence of thin films ahead of the meniscus and forming part of it, so that its periphery may extend to a distance of several diameters.

In recession, the meniscus is attached to the film on the wet walls, the periphery again being extended to several diameters. The resistance, which is usually much higher for the receding than for the advancing meniscus, varies with the length, elastic properties and strength of the thin films attached, the recessional flow being non-Newtonian and rhythmic in character[3]. In Fig. 2 is indicated the position of the thin films, which usually end in a ridge or in a filiform fringe.

A striking example of the high resistance offered in recessional flow is afforded by the results obtained in the spreading and retraction of a small pool, say of 0·05 ml. of liquid, between approaching and separating parallel flats respectively. In the approaching flats experiment, radial movement during the first stages is approximately in accord with the formula $r^4 = cFt$, where $c = 4V^2/3\pi^3\eta$ and r is the radius of the pool, F the force acting, t time, V the volume of liquid and η the viscosity. There is a curious hesitation in movement when the film reaches a film thickness of about 10 μ, due apparently to the instability and rupture of the film because of its much increased specific area, and there is a decided resistance to further spreading, which is usually filiform in character[4]. When the force is reversed to separate the plates a hysteresis effect is observed, especially when wetting is poor, as with a pool of 0·05 ml. of a glycerol–water mixture (viscosity, 150 centistokes) between glass surfaces slightly contaminated with oil. When the pool was 3·8 cm. in diameter, the time taken for the plates to separate with a force of 200 gm. weight was found to be 350 sec., which is several times the calculated value. Similarly, with a diameter of 4 cm. and the same force acting, no movement of separation was observed over 24 hr.; on scrupulously clean glass the observed time for separation was several times that of the calculated value, taking into consideration the surface tension forces tending to hold the plates together, namely, $2\pi^2r^4\,\gamma\cos\theta/V + 2\pi r\,\gamma\cos\theta$.

It appears that the cavitation of the film, observed during the separation of the plates, together with the filiform periphery, sets up additional surface tension forces to those given above.

Liquids flowing slowly over solids have highly versatile behaviours depending among other things on their molecular structure and aggregation; with toluene, less resistance to flow than with benzene was recorded, while with the xylenes the *para* isomer was found to be the most freely flowing. With binary mixtures of liquids it was possible to correlate increased spreading-rates with lower coefficients of friction and higher strengths of adhesion[1]. With pools of some aliphatic alcohols on brass, methyl alcohol spread the least, but on aluminium it spread the most; of some aliphatic acetic esters on metals and okerin surfaces, methyl acetate was less freely flowing than amyl acetate of higher viscosity.

Acknowledgment is made to the Chief Scientist, Ministry of Supply, for permission to publish this communication.

A New Type of Diffusion Cathode

RECENT progress in the field of thermionic emitters has largely been directed towards obtaining continuous current densities higher than those which can be obtained from oxide cathodes with reasonable lives. Examples of this trend are the *L* cathode[1], the impregnated tungsten cathode[2] and the moulded nickel–barium carbonate layer cathode[3].

A new type of cathode combining the features of the impregnated *W* cathode and the moulded cathode has recently been developed. The cathode is made by preparing a mixture of nickel powder and barium–strontium carbonate powder. A small percentage of an appropriate reducing agent is added to the mixture. The ball-milled mixture is loaded into a retaining cylinder, which may be of nickel, 'Kovar' or molybdenum or other suitable refractory material and is compressed using a pressure which is determined by the desired value of final porosity. Typical cathodes contain 70 per cent by weight of nickel powder, 29 per cent barium–strontium carbonate and 1 per cent zirconium hydride. Pressures of between 20 and 160 tons/in.² have been used. The retaining cylinder is then removed from the press tool and is mounted in the valve in the ordinary way, the pressed emitting material being mechanically strong and well able to resist the stresses experienced in handling and mounting.

The outgassing and activation procedures are similar to those usually employed with oxide cathodes except that the times are somewhat longer. The emission is allowed to build up to between 1–3 amp./cm.² on the pump before sealing off, and when carefully stabilized cathodes for measurement purposes are required, the cathode is aged at the same density for several hours after seal-off.

Fig. 1 shows typical pulsed-emission results for these cathodes, compared with conventional oxide cathodes and with published data for the *L* cathode. These results are very similar to those of MacNair, Hannay and Lynch. The graph also shows data representing conditions under which good modern oxide cathodes can be operated for reasonable lives and a tentative line for the new *BN* cathode. Diodes using *BN* cathodes have survived 3,000 hr. at 3 amp./cm.² and 1,070° C., and 6,000 hr. at 1·5 amp./cm.² and 1,020° C. They are resistant to ionic

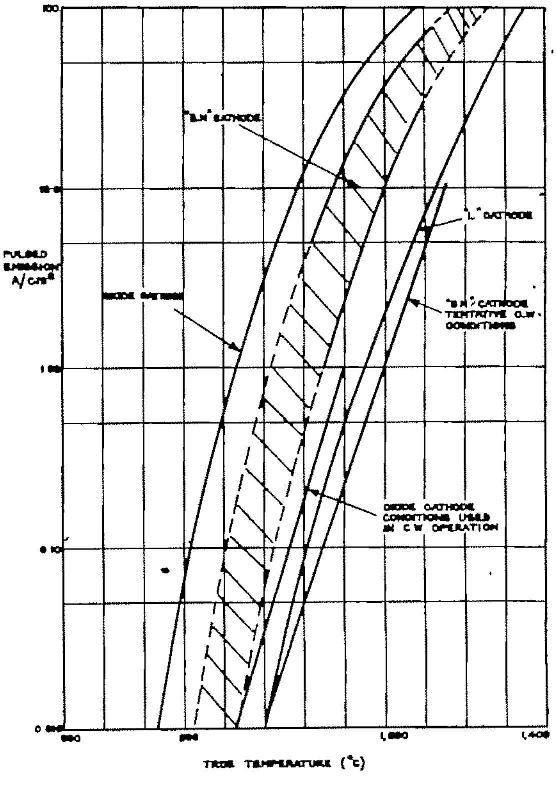

Fig. 1. Curves of emission as a function of temperature for oxide, *L* and *BN* cathodes

bombardment and have been very satisfactorily used in demountable vacuum apparatus.

Measurements of work function by the usual saturation emission method lead to a value for φ_e about 1·8 eV. Retarding field values of φ lead to a value of about 2·8 eV. We interpret these results as meaning that the emission originates from an incomplete monolayer of barium ions, with about 70 per cent surface coverage. The temperature coefficient of the work function is about $1 \cdot 4 \times 10^{-4}$ eV. per deg. K.

A paper describing this work in more detail was read at the recent Congrès International du Cinquentenaire de la Cathode à Oxydes and will be published in the Proceedings of that Congress to appear in *Le Vide*.

Thermal Expansion of Grey Tin

No work appears to have been reported on the thermal expansion of grey tin and it may be of interest, therefore, to give some X-ray measurements that we have made on this material at temperatures between room temperature and − 130° C. These are shown in Fig. 1, from which it will be seen that the coefficient of expansion is sensibly constant within the range quoted. The value actually works out to be $4 \cdot 7 \times 10^{-6}$ per degree C. The measurements were made with a 'Unicam' 19-cm. powder camera modified as described in a note to be published by us elsewhere. Unfiltered copper *K*-radiation was used.

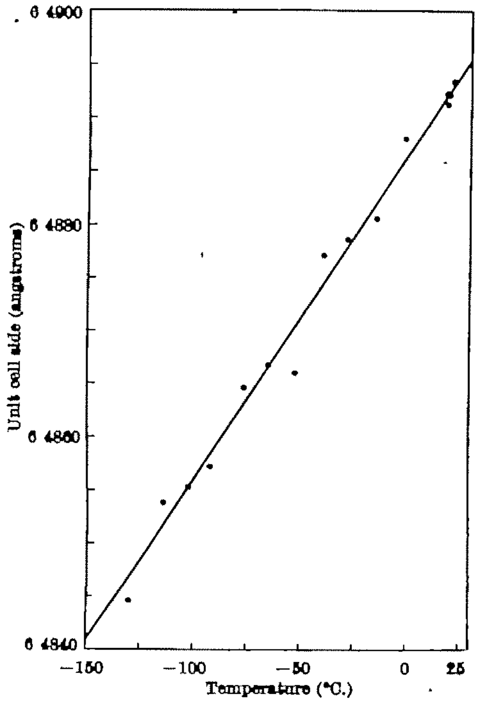

Fig. 1. Thermal expansion of grey tin

The value of the unit-cell side, 6·4892 ± 0·0001 A. at 20° C. (assuming 1·54050 A. for the wave-length of copper $K\alpha_1$), is significantly less than that reported by Brownlee[1], namely, 6·4912 ± 0·0005 A. However, the nature of our curve and the measurements actually made at room temperature (on two different specimens) suggest that our results are substantially correct, especially as the values of the lattice parameters of other materials obtained with the same camera under similar conditions are found to agree with the accepted values for these parameters within the experimental error claimed. We are informed by the Tin Research Institute, to which body we should like to express our thanks for supplying the tin, that the purity of the material we examined was 99·99 per cent, the main impurities being lead and antimony. These impurities would account at most for an error of about the same magnitude as our experimental error, and therefore the discrepancy is left unexplained.

Mr. J. T. Kendall, who supplied the tin used by Brownlee, has informed us that his sample was also very pure, being prepared from Johnson–Matthey's 'spectroscopically pure' material.

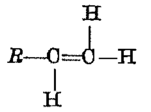
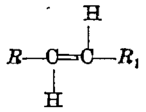
Infra-Red Assignments of Unsaturation in the Region 900–1,000 cm.$^{-1}$

The region 900–1,000 cm.$^{-1}$ of the infra-red spectrum of organic molecules is useful for characterizing the type of unsaturation that may be present. This region is associated with the bending frequencies of hydrogen attached to an olefinic carbon. Thus the groups



$$R-\underset{H}{C}=\overset{H}{C}-H$$

and



$$R-\underset{H}{C}=\overset{H}{C}-R_1$$

give rise to characteristic bands at 909–916 cm.$^{-1}$ and 964–979 cm.$^{-1}$ respectively[1].

Recent work by Jackson *et al.*[2] and Privett *et al.*[3] on the linoleates has enabled further assignments to be made in this region. *Trans-trans* conjugation is characterized by an absorption band at 988 cm.$^{-1}$, whereas *cis-trans* conjugation is characterized by absorption bands at 948 and 982 cm.$^{-1}$. However, when the spectrum of all *trans* vitamin A (which has five conjugated double bonds) is examined, there is one very strong band in the region 900–1,000 cm.$^{-1}$, but this lies at 968 cm.$^{-1}$, a position which is normally held to characterize only an isolated *trans* unsaturated bond. This is illustrated in Fig. 1, which shows the infra-red absorption spectrum of vitamin A palmitate, the 968 cm.$^{-1}$ band being characteristic of both the free alcohol and of its esters. The spectrum of β-carotene, which is a precursor of vitamin A and contains eight conjugated double bonds, is also similar in this respect.

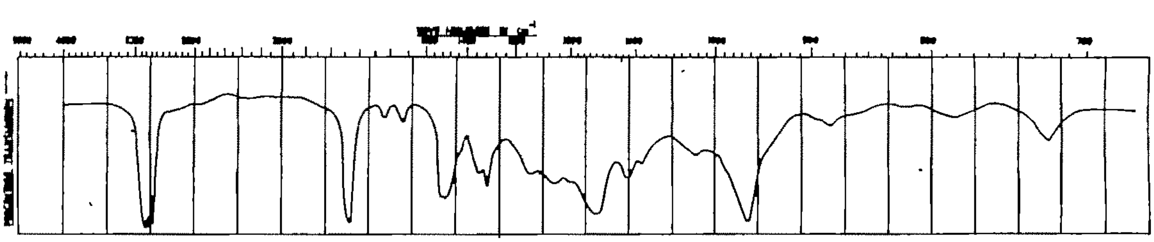


Fig. 1. Infra-red absorption spectrum of vitamin A palmitate

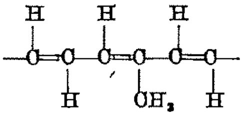
The molecular structures of these compounds show a branched methyl group on alternate double bonds thus:



$$—\overset{H}{C}=\underset{H}{C}—\overset{H}{C}=\underset{CH_3}{C}—\overset{H}{C}=\underset{H}{C}—$$

and since the hydrogen bending vibration in the $CHR_1 = CHR_2$ (*trans*) group appears to behave as though isolated and unaffected by this type of conjugation, it is to be expected that a band arising from the hydrogen bending vibration in the group $CR_1R_2 = CHR_3$ would occur in the region 803–833 cm.$^{-1}$. In fact, however, only a very weak band near 825 cm.$^{-1}$ occurs in the vitamin A spectrum.

In the C = C stretching region, if the $CHR_1 = CHR_2$ (*trans*) and $CR_1R_2 = CHR_3$ groups behaved as isolated non-conjugated groups, two bands would be expected[4] to occur near 1,670 cm.$^{-1}$; in fact, however, two bands at 1,623 cm.$^{-1}$ and 1,565 cm.$^{-1}$ are observed (Fig. 1), showing that the conjugation does affect the C = C stretching vibration.

From the practical point of infra-red analysis of unknown materials, although the 968 cm.$^{-1}$ band is generally assigned to isolated (non-conjugated) *trans* unsaturated bonds, it follows from the above that this is not always correct.

Iodometric Assay of Penicillinase

The series of iodometric methods[1] for assaying penicillinase reported here permits enzyme activity to be measured easily over wide ranges of *p*H and temperature, with higher speed, accuracy or sensitivity than were previously attainable[2]. Although designed for the penicillinase of *B. cereus* NRRL-569, it appears likely that they may be equally suitable in principle for penicillinase from other sources. 'Unit rate of penicillin destruction' is used here to mean a destruction-rate of 1 µmol./hr. Since the amount of a penicillinase which will give unit rate of destruction depends on the nature of the enzyme and the conditions to which it is exposed, a 'unit dose' (U.D.) of *B. cereus* NRRL-569 penicillinase is here defined as that amount of the enzyme which gives unit rate of destruction when exposed to 0·005 *M* sodium benzyl penicillin in 0·2 *M* potassium phosphate buffer at *p*H 6·5 and 30° C. The commercial crystalline sodium penicillin *G* of Glaxo, Ltd., is used in the following assays; its potency is stated to be 1,650 I.U./mgm.

Before performing an accurate assay it is necessary to know the approximate activity of the enzyme sample, which is determined in the following manner. To 50 ml. of 0·0014 *M* penicillin in 0·02 *M* phosphate buffer, *p*H 6·5, is added 2 ml. of 2 per cent sodium starch glycollate[3] and 0·01 *N* iodine, dropwise, until a faint blue colour persists for 3 min.: a further 6 ml. of iodine is then added. This deep-blue reagent, freshly prepared, is mixed in a test-tube in the proportion of 2·5 ml. to 0·5 ml. of enzyme, and the time-interval until decolorization is noted. At a room temperature of about 22° C. the product, *P*, of activity and time is constant within ± 10 per cent, for purified enzyme samples, over a time-range of about 0·5–15 min., which corresponds to an activity range of between 60 and 2 U.D. of enzyme. If crude preparations of enzyme with a high non-specific iodine uptake do not give a constant value for *P*, standards of known activity are included in each run. Two operators can assay about fifty samples an hour by this method.

The accurate version of the assay is carried out as follows. A stoppered 60-ml. reagent bottle containing 5 ml. of an ice-cold 0·007 *M* solution of penicillin in 0·2 *M* phosphate buffer, *p*H 6·5, is mounted so that it can be gently shaken in a water-bath at 30° C. The enzyme for assay, pre-warmed to 30° C., is added after 10 min.: it should consist of not more than 20 U.D. of activity in not more than 2 ml. of solution containing 0·5 per cent gelatin[4]. After a further 30 min., shaking is stopped, and the enzyme reaction arrested by adding 10 ml. of an iodine reagent also prewarmed to 30° C.; this reagent is 0·0166 *N* iodine, 0·06 *M* potassium iodide and 1·75 *M* sodium acetate buffer, *p*H 4·00. Ten minutes later, the bottle is removed from the bath and titrated with 0·0166 *N* thiosulphate: if the titration is less than 4·5 ml., the assay is repeated with diluted enzyme. Under these conditions, 1 ml. 0·0166 *N* iodine is equivalent to 2 µmol. of penicillin destroyed. Corrections for spontaneous decay of penicillin and the iodine uptake of crude enzyme samples are determined from suitable controls. By starting assays at 3-min. intervals, two operators can perform ten in an hour. Accuracy of the method is within the limits of good volumetric technique: sensitivity is 0·04 U.D. of enzyme, but may be increased ten-fold by lengthening the reaction-time to 5 hr.

This accurate assay may be modified to work over a wide range of conditions providing certain properties of the system are taken into account: (*a*) the K_m of *B. cereus* NRRL-569 penicillinase is about 7×10^{-5} *M*; the influence of *p*H and temperature on its effective rate of destruction of penicillin under certain conditions is shown in Figs. 1 and 2 (these properties

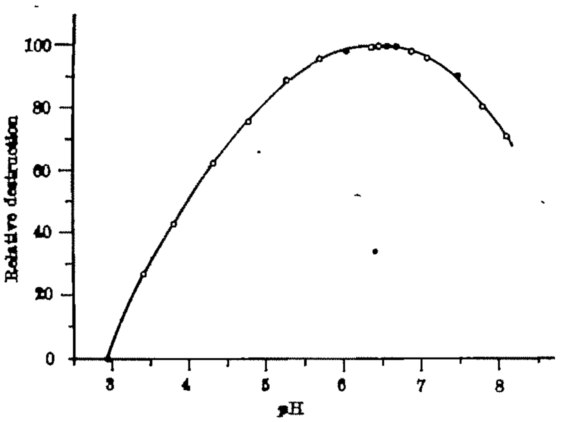

Fig. 1. Penicillin destroyed by a constant initial amount of enzyme at various pH's, expressed as percentage of penicillin destroyed at pH 6·5. Time 30 min.; temperature 30° C.; phosphate-citrate buffer. Each point is the mean of two determinations

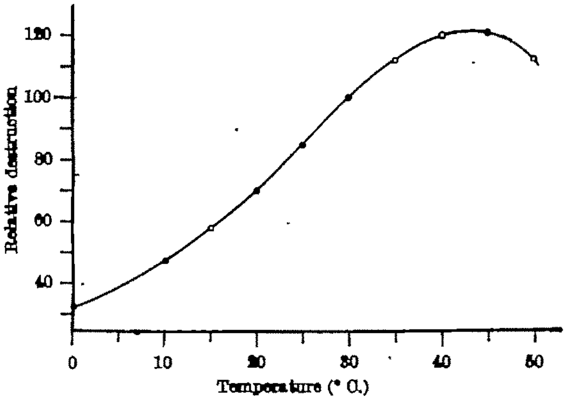

Fig. 2. Penicillin destroyed by a constant initial amount of enzyme at various temperatures, expressed as percentage of penicillin destroyed at 30° C. Time 30 min.; pH 6·5; phosphate buffer. Each point is the mean of three determinations

were determined by iodometric methods and differ slightly from those previously reported[3]); (*b*) a residual iodine concentration of at least 0·0045 *N* at the beginning of the titration seems desirable; (*c*) under the conditions described, the degradation products of 1 molecule of penicillin reduce 8·3 atoms of iodine: under other conditions, that particular relationship will probably not apply[1], and the iodine equivalence must be re-determined using the product of complete enzymic degradation of a known amount of penicillin.

A very sensitive means of detecting penicillinase exploits the widely different partition coefficients of iodine and iodide between carbon tetrachloride and water. If penicillin partially degraded by penicillinase is shaken with a solution of iodine labelled with iodine-131 in carbon tetrachloride, the aqueous phase acquires an amount of radioactivity, in the form of iodide, which is a function of the amount of penicillin destroyed. With highly purified enzyme, 2×10^{-4} *M* penicillin and 5×10^{-4} *N* iodine containing 10 μc. iodine-131/ml., it has proved possible to detect 3×10^{-4} U.D. of penicillinase (about 4×10^{-19} mol. of enzyme if its molecular activity[5] is $1 \cdot 3 \times 10^{5}$). Unfortunately, the conditions for attaining such sensitivity are so rigorous that further refinement of the method seems useless.

The iodine – penicilloic acid reaction can also be used for identifying colonies of penicillinase-producing bacteria in solid media. The indicator is incorporated in the medium; after incubation, the plate is flooded with 0·1 *M* penicillin and left for 15 min. or more at 2° C. The penicillin is then replaced by iodine of suitable strength (depending on the nature of the medium and the activity of enzyme present). Colonies of penicillinase-producers are surrounded by colourless zones which increase in area with time.

These methods and their experimental justification will be reported elsewhere in detail. I am grateful to Miss Daphne Towler and Miss Audrey Hearle for expert technical assistance.

Utilization of Formate-^{14}C for Synthesis of Deoxyribonucleic Acid by Human Bone Marrow Cells *in vitro*

Previous publications[1,2] have reported on the incorporation of adenine-^{14}C into ribonucleic acid and deoxyribonucleic acid by human bone marrow cells *in vitro*. Using a high-resolution autoradiography technique[3], the grain counts over the individual cells before and after hydrolysis with *N* hydrochloric acid at 60° C. for 6½ min. indicated a slightly larger amount of adenine-^{14}C incorporated into ribonucleic acid than into deoxyribonucleic acid, in 24-hr. cultures (see Fig. 1).

Similar experiments were performed using 0·75 μc./ml. sodium formate-^{14}C in the culture medium. Isomolar (0·75 millimolar) concentrations of formate-^{14}C and adenine-^{14}C were used, these concentrations being in excess of those permitting maximum

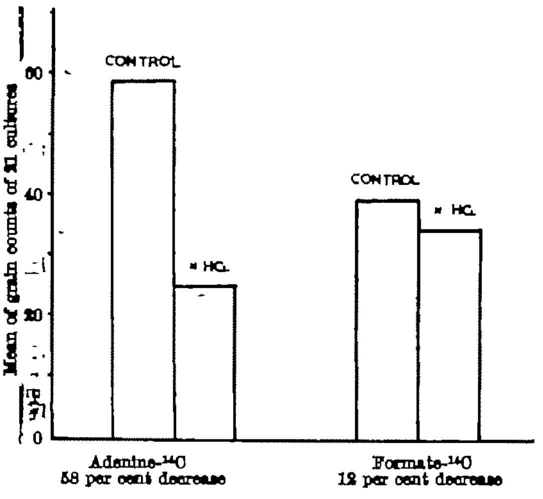

Fig. 1. Effect of *N* hydrochloric acid at 60° C. for 6½ min. on the carbon-14 content of cells

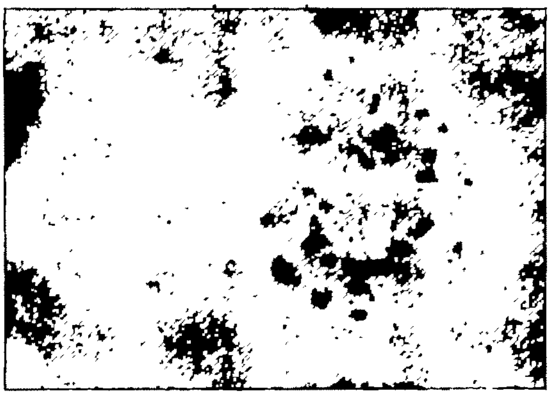

Fig. 2. Formate-^{14}C uptake by human bone marrow cells *in vitro* in 24-hr. culture with 0·75 μc./ml. formate-^{14}C medium. Smear alcohol fixed, not acid hydrolysed. Stained autoradiograph, × 2,000. Note the localization of the isotope in the chromosomes

uptake by the cells. The difference in the specific activities (1·04 mc./m*M* for formate-^{14}C, and 1·56 mc./m*M* for adenine-^{14}C) was compensated for in the exposure times of the autoradiographs, namely, ten days for adenine-^{14}C slides and seventeen days for formate-^{14}C slides. The grain counts on the acid-hydrolysed slides indicated a similar amount of carbon-14 uptake in both cases, the average maximum uptake being of the order of 1·2 × 10^7 atoms of deoxyribonucleic acid-^{14}C.

However, the comparison of the non-hydrolysed and acid-hydrolysed preparations from the formate-^{14}C cultures indicated scarcely any change in the average maximum grain counts after hydrolysis (see Fig. 1). The failure of acid hydrolysis to remove appreciable amounts of carbon-14 from the cells, together with the predominantly nuclear (and chromosomal) localization of the isotope on the non-hydrolysed preparations (Fig. 2), indicated that, as opposed to adenine-^{14}C, most of the formate-^{14}C taken up by human bone marrow cells *in vitro* is incorporated into deoxyribonucleic acid, and only a very small fraction is incorporated into other compounds (for example, ribonucleic acid).

These findings are at variance with those obtained in rat liver with formate-^{14}C [4,5]; but the cause of the difference may lie in the different rates of synthesis of deoxyribonucleic acid in bone marrow and resting liver. There is evidence that in chick bone marrow slices more than 70 per cent of the formate-^{14}C in deoxyribonucleic acid is found in the methyl group of thymine[6], and preliminary experiments in our laboratory also indicate that probably most of the formate-^{14}C administered to human bone marrow cells *in vitro* is incorporated into thymine in deoxyribonucleic acid.

This work is part of an investigation carried out under a full grant from the British Empire Cancer Campaign.

Cocarboxylasic Activity of Thiamine Phosphoric Esters

AFTER the chemical synthesis of thiamine phosphoric esters was achieved[1–4], reports were published on their cocarboxylasic activity[5–7]. Investigations have shown that monophosphothiamine has no cocarboxylasic activity, but different values have been found for the activity of triphosphothiamine. The discrepancies may be accounted for by the facts that: (*a*) chemical synthesis provides mixtures of three esters (mono-, di- and tri-phosphoric) which are very difficult to separate; (*b*) diphosphothiamine is very active; and therefore quantities as small as 0·1 γ/ml. occurring as impurities with the other esters invalidate the results; (*c*) washed yeast, which has usually been employed as apoenzyme, makes it difficult to reproduce results.

We have separated the esters by paper chromatography[7], employing Whatman No. 1 paper and *n*-propanol – water – 1 *M* acetate buffer, *p*H 5 (70 : 20 : 10), as the solvent.

The position of each ester was established by developing duplicate spots in parallel and spraying one of the series. Fragments of strips not sprayed were placed in Warburg flasks and compared with known amounts of chromatographically pure diphosphothiamine under identical experimental conditions.

As apoenzyme we have used purified apocarboxylase according to Green *et al.*[8]. Each flask contained: an amount of apoenzyme which in the presence of excess (80 γ) of diphosphothiamine produces carbon dioxide at 4·0 × 10^3 μl./hr.; 0·27 mgm. of magnesium ions and 0·19 mgm. of manganese ions; in the side bulb, 0·4 ml. of 1·09 *M* sodium pyruvate; 0·04 *M* citrate buffer, *p*H 6·0, making up the volume to 3·0 ml.; temperature, 30° C.; atmosphere, air; shaking, 160–170 oscillations/min. The rate of evolution of carbon dioxide was determined by a graphical method[9]. The manometers were read every 2 min. after allowing 15 min. for the establishment of equilibrium. The quantities of each ester were established by colorimetric determination of phosphorus[10].

The following results were obtained: (1) monophosphothiamine at concentrations of 0·025–0·13 μmol./ml. did not manifest any cocarboxylasic activity; (2) diphosphothiamine at a concentration of 0·04 μmol./ml. liberated carbon dioxide at the rate of 2·3 × 10^3 μl./hr.; (3) triphosphothiamine at concentrations of 0·005–0·020 μmol./ml. did not manifest any cocarboxylasic activity.

A Further Serological Distinction between the Hæmagglutinins of *Dolichos biflorus* and *Phaseolus lunatus*

SEED hæmagglutinins have recently been investigated in considerable detail. Many botanical species contain non-specific agglutinins for human erythrocytes and some contain agglutinins which are relatively or absolutely specific[1-4].

Krupe[4] has demonstrated the presence of incomplete antibodies in various seeds. The action of seed agglutinins on enzyme-treated cells is now being investigated in our laboratories. The enzyme used is papain and the technique that described by Stratton[5]. Detailed results will be published in due course.

Bird[6] has directed attention to the fact that there is a difference in the serological reactions of extracts of two *A*-specific seeds, *Dolichos biflorus* and *Phaseolus lunatus*. The former act strongly on A_1 and A_1B cells and relatively weakly on A_2 and A_2B, whereas the latter act more uniformly on these sub-groups.

The present communication reports a more marked serological distinction between the two agglutinins. *Phaseolus lunatus* extracts act upon papainized erythrocytes of groups *B* and *O*, whereas *Dolichos biflorus* extracts retain their specificity for *A* cells when tested under identical conditions (see table).

TITRES OF UNTREATED AND PAPAINIZED CELLS AGAINST *A*-SPECIFIC SEED EXTRACTS

	Untreated cells Group			Papainized cells Group		
	A	*B*	*O*	*A*	*B*	*O*
Dolichos biflorus	1,024	0	0	32,768	0	0
Phaseolus lunatus	2,048	0	0	65,536	8	8

These observations are in keeping with the fact that extracts of some varieties of *Phaseolus lunatus* act weakly on *B* and *O* cells[2], and the observation that these extracts act strongly on panagglutinating (infected) cell suspensions irrespective of their *ABO* group (unpublished results). On the other hand, *Dolichos biflorus* extracts are not known to act on *B* and *O* cells, and do not lose their specificity when tested with panagglutinating cell suspensions (unpublished results).

It appears that *Dolichos biflorus* agglutinins have a greater degree of specificity for the agglutinogen *A* than was originally appreciated.

Mechanism of Hypotensive Action of Reserpine, an Alkaloid of *Rauwolfia serpentina*

STUDIES on the pharmacology of extracts of *Rauwolfia serpentina* have been reported by Chopra, Gupta and Mukherjee[1], Ray *et al.*[2] and Dasgupta *et al.*[3]. Chopra, Gupta and Mukherjee[1] reported that the alkaloid with which they were working had a marked hypotensive effect which was in part due to depression of central nervous mechanisms, since it was less marked in decerebrate animals, but appeared also to result in part from a direct inhibitory effect on the musculature of the blood vessels. They demonstrated also a fall in the output of the isolated heart. Most subsequent work has suggested that the hypotensive effect of *Rauwolfia* alkaloids is mediated solely via central nervous mechanisms.

A new alkaloid, now named reserpine, was isolated by Müller, Schlittler and Bein[4], and pharmacological studies on the action of this alkaloid have been published by Bein *et al.*[5], Bein[6], and Trapold *et al.*[7]. Their results were in conformity with those of other workers on *Rauwolfia*, who reported it to act via the central nervous system, and they emphasized particularly its capacity to inhibit reflex pressor responses.

Our own studies have confirmed that reserpine diminished reflex vasomotor responses, but have also demonstrated a direct effect on the peripheral vessels independent of its nervous activity. This action is most clearly seen in the rabbit; we employed the preparation devised by Gallagher[8], in which the innervated but otherwise isolated hind-limb is perfused with a blood–dextran medium at constant rate. Changes in vasomotor tone in the limb are indicated by alterations in perfusion pressure. We have found that injections of reserpine into the systemic circulation of the rabbit produce an immediate fall in systemic blood pressure. This is accompanied by an immediate rise in limb perfusion pressure instead of a fall, as would have been expected were the fall of blood pressure mediated through the nervous system. Furthermore, injection of reserpine directly into the artery of the perfused hind-limb causes immediate diminution in vasomotor tone. Reserpine has also been shown to have a depressant effect on the action of vasopressor substances injected into the isolated rat hindquarter preparation and on the response to nervous stimuli of isolated portions of rat diaphragm. A feature of all these reactions is their remarkably prolonged duration, suggesting binding of the drug by the musculature.

We have also obtained evidence that such a direct peripheral effect may play some part in the hypotensive action of reserpine in man. We have found that the blood pressure in the supine position can be brought to a lower level by the combined action of reserpine and large doses of hexamethonium bromide than by hexamethonium alone.

Papers embodying the results of these studies are being prepared and will be published elsewhere.

A Centrifuging Method for Root Sterilization

In isolating mycorrhizal fungi present in root tissues, the external surfaces must be sterilized without damaging the hyphæ within. Existing techniques involving chemical sterilization or removal of the epidermis under aseptic conditions were found to be unsatisfactory in *Calluna vulgaris* and *Vaccinium myrtillus*, as they involved loss of hyphæ in the epidermis where the hyphæ were concentrated. Accordingly, a centrifuging technique was devised which obviated these difficulties.

The apparatus consists of a small glass tube, fitted into a 'Pyrex' centrifuge tube. A piece of fine muslin is stretched across the top of the inner tube and secured by waterproof adhesive tape. The base of the inner tube is wrapped in cotton wool. This is essential for even distribution of pressure during centrifuging. Sufficient sterile water is added to cover the muslin.

The roots to be surface-sterilized are thoroughly washed in detergent before being placed on the muslin of the inner tube. They are then centrifuged for three to four minutes at 7,500 rev./min., removed and shaken vigorously in two tubes of sterile water to dislodge contaminants still attached to the root surface. Prior to each centrifuging, 50 per cent alcohol is used to sterilize the apparatus. Three times in the centrifuge, each time followed by agitation in two tubes of sterile water, except after the last, when four tubes are used, results in a high proportion of surface-sterile root sections 3–5 mm. in length.

Environmental Determination of the Sex Ratio of a Plant Parasitic Nematode

The sex ratio of the potato root eelworm *Heterodera rostochiensis* Wollenweber has been under investigation in this laboratory since 1950. From the first it appeared that the ratio is very variable; it is now clear (*a*) that the ratio can be different on primary and lateral roots, and (*b*) that it varies with the intensity of infection.

Plants were raised in pots and grown either on a laboratory window bench or in the field: either they were grown in soil containing eelworm cysts or in sterile sand to which larvæ were added afterwards. As earlier stages are difficult to identify with reasonable ease and certainty, all plants were lifted when the males were adult but still 'encysted'; at this stage females are swollen but still within the root tissues. But as the males leave the roots soon after, care was taken to lift the plants in time. The roots were then carefully washed, treated with lactophenol-acid fuchsin in the standard way[1], and the number of adult males and females counted with the aid of a dissecting microscope; no attempt was made to sex early stages, but the total number of worms was noted. Although most of the worms are readily visible, it was nevertheless necessary more or less to dissect the root system to ensure that all worms were found; and, in the case of the field-grown plants where the root system was particularly extensive, sometimes only a sample of the root system was examined. I am most grateful to Mrs. E. Capstick for the care with which she carried out these examinations.

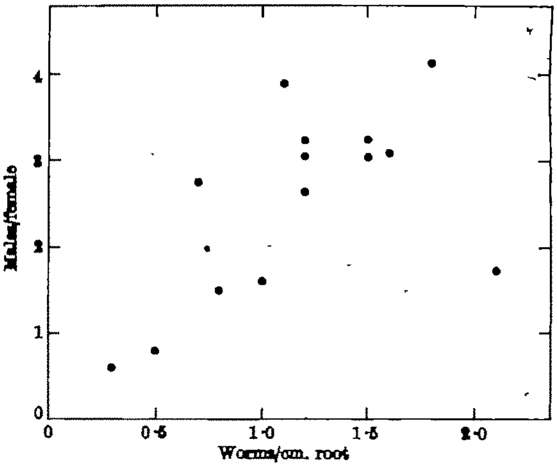

Fig. 1. Increasing proportion of males with increasing intensity of attack

The results for fourteen plants, part of a typical experiment with a number of potato varieties, are shown in Fig. 1; the different plants are compared on the basis of the length of primary roots of the root system examined. The sex ratio (males per female) is plotted against intensity of attack; it will be seen that, as the intensity increases, a higher proportion of males is found, the sex ratio changing from about 1 : 2, at the lower levels, to about four males to one female at the upper end; and higher values have frequently been found. 'Intensity of attack' was estimated from the number of worms of all stages per cm. of primary root, although, of course, worms in both primary and lateral roots are included. The method is not beyond criticism; indeed, an investigation of alternatives, such as the exclusion of juveniles, may itself help to clarify the situation. But other standards do not alter the general trend: the higher the intensity of attack, the higher the proportion of males, or the lower the reproductive rate.

Clearly, the phenomenon may help to explain the puzzling manner in which soil populations of the potato[2,3] and the closely related beet eelworm (*H. schachtii*)[4] increase; for the rate of multiplication decreases with the number of eelworm eggs in the soil.

A fully developed female with her many hundreds of eggs must be a considerable drain on the host plant. Whatever the mechanism, therefore, a reduction in the relative number of females with intensity of attack is a remarkable adaptation. There appear to be two possibilities: either the change in sex ratio is achieved as a result of a differential death-rate; or it is due to environmental influence on the process of sex determination.

A differential death-rate could operate by eliminating a progressively higher proportion of females before they reach the host plant; alternatively, progressively more females might fail to reach maturity within the plant. Careful examination of a number

Table 1. Distribution of Sexes on Primary and Lateral Roots. Figures are mean values per plant for young plants grown in pots to each of which 900 larvæ were added

	Adult male	Adult female	Male/female	Unclassified
Primary	38·3	23·8	1·61	24·9
Lateral	172·9	20·7	8·35	45·1

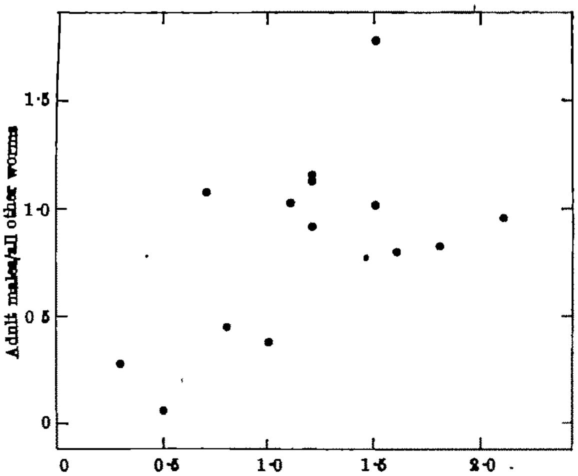

Fig. 2. For this diagram, all worms, other than adult males, have been assumed to be potential females. The increase in the proportion of males, with increasing intensity of attack, is therefore not due to a higher death-rate of females within the host plant

of plants grown in sterile sand to which larvæ were afterwards added showed in every case that the proportion of males to females was very much higher on the lateral roots than the primary roots from which they arose. The mean values are shown in Table 1; there are roughly five times more males per female on the lateral roots than on the primaries. The figures for the unclassified worms show that the difference cannot be due to any difference in rate of development, for the proportion of unclassified worms is rather higher on the primaries. This difference between primary and lateral roots would appear to eliminate the possibility of differential soil death-rate—unless it were also associated with a male preference for lateral roots.

We are confident that the worms counted as neither adult nor female were in fact juveniles and not corpses. Nevertheless, although they show no obvious signs of degeneration, it must be admitted that it may not be easy to distinguish between an eelworm which has died of natural causes and one which has been freshly killed by the fixative. Accordingly, all worms were counted as female which were not adult male; that is, all previously unclassified worms were added to the female total. The recalculated and heavily weighted 'sex-ratios' have been plotted against intensity of attack in Fig. 2; even in such unfavourable circumstances, they still show a very strong trend, the proportion of males increasing with increasing intensity of attack. This is decisive evidence against a differential death-rate in the host as the cause of the trend. Clearly, the process of sex determination is under environmental influence.

This work forms part of a programme supported by grants from the Agricultural Research Council. I am also grateful for a personal grant from the Nuffield Foundation in 1953.

Eradication of *Venturia inaequalis* (Cooke) Wint.

The control of apple scab or black spot, caused by *Venturia inaequalis*, using protective and eradicant-protective spray programmes during the parasitic phase of fungal activity has reached a stage beyond which further substantial improvement is unlikely. With modern machinery and modern chemicals, good control of the disease can be achieved in normal seasons in New South Wales, but the cost of the control programme is very high and heavy losses still occur under extreme infection conditions.

In 1937, Keitt and Palmiter[1] reported failure to eradicate the disease by attempting to break the cycle of fungal development with autumn foliage sprays of copper – lime – arsenite mixtures and with a late-winter ground spray of ammonium sulphate. Since then many attempts have been made to break the cycle during the saprophytic phase, using eradicant ground sprays. These attempts to kill the maturing perithecia have failed to eradicate the disease, due to the impossibility of hitting all fallen leaves with the chemical and to the incompletely eradicant action of some of the chemicals used.

The use of eradicants in the pre-leaf-fall period to prevent the fungus entering the saprophytic phase has received much less attention, and consequently a re-investigation of this aspect was undertaken using some new eradicant fungicides. Of these, phenyl mercuric chloride appeared most promising. In numerous reports, such as those of Fitzgibbon[2] and of Marsh[3], its outstanding fungicidal ability and low phytotoxicity at low concentration have been stressed. In 1952, Byrde *et al.*[4] reported the successful use of this chemical at high concentration as an autumn spray in preventing sporulation of *Nectria galligena* Bres. on apple trees, thereby demonstrating its extreme eradicant action and non-phytotoxicity.

In late autumn (May) 1953 at Orange, New South Wales, sprays of phenyl mercuric chloride (0·3 per cent), sodium pentachlorophenate (0·5 per cent) and sodium dinitro-*o*-cresylate (0·5 per cent) were applied to Delicious apple trees heavily infected with black spot. The latter chemical caused much leaf burning and leaf rolling, but did not damage bark or buds. The other two materials caused no injury.

Two weeks after spraying, when the foliage was falling freely, samples of leaves from each treatment and unsprayed leaves were collected and allowed to over-winter under orchard conditions at Orange. From the end of September sub-samples from each were examined at weekly intervals for the presence of perithecia and for perithecial maturity as determined by intensity of ascospore discharge in the laboratory.

In the unsprayed leaves perithecia were abundant, ascospore discharge commenced in late September, rose to maximum intensity in early November, fell away quickly at first and then gradually, until it ceased at the end of January.

In the leaves sprayed with phenyl mercuric chloride, no mature perithecium was observed and from these leaves no ascospore of *Venturia inaequalis* was discharged during the testing period (October 2–December 31). Both discrete and diffuse scab lesions were observed on most of the leaves, and the absence of perithecia suggests that the fungus was killed in the sub-cuticular stromatic layer before the initiation of the saprophytic phase.

Sodium dinitro-*o*-cresylate caused a considerable reduction in effective perithecial development, and this was reflected in a low rate of discharge of ascospores.

Perithecia were plentiful in the leaves sprayed with sodium pentachlorophenate and were more advanced in maturity than those in the unsprayed leaves, ascospore discharge reaching peak intensity in mid-October. The rate of ascospore discharge was greater than from the leaves sprayed with sodium dinitro-*o*-cresylate but much less than that from the unsprayed leaves.

Further investigations have been undertaken this autumn (March–May) to determine the minimum concentration of phenyl mercuric chloride for eradication of *Venturia inaequalis* from infected apple leaves, and to test the possibility of eradicating apple scab from heavily infected isolated orchards using phenyl mercuric chloride at high concentration immediately after the completion of harvesting. It is hoped that this eradication measure will also eliminate the fungus from infected bud-scales, a source of inoculum demonstrated by Cass Smith *et al.*[5] to be important in the disease cycle.

Full details of the techniques employed and results obtained in these investigations will be published elsewhere.

I wish to thank the field horticulturists of the N.S.W. Department of Agriculture who are assisting with these investigations, and Mr. E. C. Whittaker, fruit officer at Orange, in particular, whose co-operation in applying the sprays and forwarding sub-samples of leaves made possible the initial investigation.

Concentration of Potato Root Diffusate by Vacuum Distillation

POTATO root diffusate, which is the liquid obtained by leaching growing potatoes with water, has long been known[1] to contain an active factor which causes the larvæ to emerge from eggs contained within cysts of the potato root eelworm, *Heterodera rostochiensis*. Since the War, considerable research has been carried out in an attempt to ascertain the chemical constitution of the active factor[2]. At normal room temperature potato root diffusate is extremely unstable; hence the diffusate is stored in refrigerators, where it remains relatively stable for a considerable time.

Some method of concentrating the diffusate was imperative because it was becoming increasingly difficult to store bulk quantities of diffusate in refrigerators. The convenience of storage was the main reason for concentrating the diffusates, but other factors are also of importance.

Dilutions of the concentrate could be used for a large number of assays at the same time, hence ensuring that each experiment received the same hatching stimulus and thus removing one difficulty normally encountered in eelworm assay. Moreover, the gradual decomposition of a sample of root diffusate can be corrected by concentration and subsequent redilution. There is no reason for supposing that concentrated root diffusates differ from ordinary samples in their rate of decomposition, so that while tests are being carried out on their relative stability, the concentrates are kept at 3–4° C.

It was decided to prepare the concentrate by vacuum distillation at 5° C. and a pressure of 1 mm. mercury; the water which distilled was collected at $-20°$ C., until the volume remaining in the still was between 1 and 4 per cent of the original. In some samples further concentration was effected by freeze drying. Afterwards, dilutions were prepared for biological assay so that concentrations lay on a logarithmic scale[3].

Results showed that 90–95 per cent of the active principle remained undecomposed after vacuum distillation when comparing the diluted concentrate against the original sample. A rather greater loss, of 30 per cent, occurred with the freeze-dried material.

For all samples investigated an optimum hatch was observed (Table 1), confirming the suggestion by Calam *et al.*[2]. For concentrations higher than that which produce the optimum hatch, fewer larvæ emerged from the cysts. Thus two widely spaced concentrations of the hatching stimulant produce similar hatches, and this introduces complications into the bioassay of this substance, for which no chemical assay is as yet available.

Table 1. PERCENTAGE HATCH OF LARVÆ FROM CYST

Exp.	Dilution of root diffusate							
	$\frac{1}{1}$	$\frac{1}{4}$	$\frac{1}{16}$	$\frac{1}{64}$	$\frac{1}{256}$	$\frac{1}{1024}$	$\frac{1}{4096}$	Original sample
A	20	33	40	88	18	12·5	7·6	44
B	78	79	84	78	65	43	19	87
C	4	33	62	29	17	16	7	41

It is not yet certain whether the reduced hatch at higher concentrations is due to inhibition by soil nutrient salts or to the root diffusate factor itself. Recent experiments in which the potatoes, grown in silver sand, are leached with distilled water, suggest that the inhibition is associated with enhanced concentrations of the hatching factor.

Augmentation of Wool-growth by l-Thyroxine and Tri-iodo-thyronine in Sheep

THE photoperiodic response giving increased wool-growth in sheep[1] having been demonstrated, we are now endeavouring to trace the mode and function of this response. One section of a series of experiments designed to cover this aspect involved the use of hormone-replacement therapy. This required the acceptance as a working hypothesis that the pituitary gland is stimulated by the photoperiodic treatment so as to increase the output of the various hormones known to be associated with it, resulting finally in an increased rate of wool-growth. The availability of hormones restricted the number which could be used to three.

Ten mature Corriedale ewes were randomized on a live-weight basis into four groups. They were housed in four adjacent pens of the same shed, each pen containing a complete group. Exactly the same standard maintenance ration of concentrates and chaffed lucerne hay was fed daily to all groups throughout the experiment. This resulted in maintaining the body-weight of the control group fairly constant until shearing in mid-October, when, as would be expected, the weight of all groups fell by the weight of wool removed, that of the control group remaining constant thereafter.

The three hormones used were: (*a*) 1-thyroxine injected subcutaneously as an aqueous solution totalling 92 mgm. per ewe over the period; (*b*) tri-iodo-thyronine injected subcutaneously as an aqueous solution totalling 30 mgm. per ewe over the period; (*c*) anterior lobe pituitary extract administered orally in pill form, totalling 92½ grains of desiccated substance over the period.

The method was to use a dose-level above the physiological range to some extent indicated by Maqsood's use of thyro-active iodinated casein[2], until definite biological activity had been established by a sharp loss of live weight amounting to about 8 lb. per ewe. The succeeding doses were then spaced so as not to bring about a further alteration in live weight during the period.

Every month the wool was clipped from similar areas of skin on each sheep, clean scoured and weighed dry. The dry weight of wool clipped from each ewe in any one month was then expressed as a ratio of the same ewe's monthly production from the same area of skin during the previous December–January–February period, when nutritional conditions were identical for all sheep. Thus for each ewe the wool-growth curve at its maximum[3], is used as a standard to which subsequent production can be related. The group means have been plotted in this manner in Fig. 1, which in addition shows the period when the hormones were administered relative to the responses obtained.

During the period, the increases in wool-growth obtained from the thyroxine and tri-iodo-thyronine groups are substantial and statistically significant. It will be further noted that cessation of the injections resulted in a return to the normal curve of the controls, with which wool-growth conformed thereafter.

The obvious failure of the anterior pituitary extract to produce any effect on wool-growth may be explainable in two ways: (*a*) it has not yet been possible to trace the source from which the extract was manufactured; if this was, as appears likely, ox pituitaries, then it could be possible for the sheep injected with this substance to produce an immunity, thus preventing any biological action taking place, or (*b*) the dose-level was not high enough to cover the inefficiencies of oral administration.

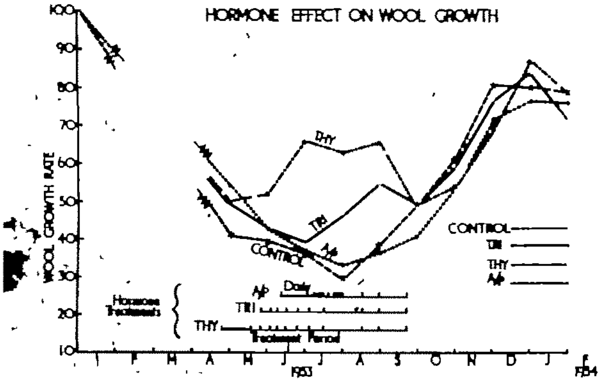

Fig. 1

These experiments are being continued and will be reported more fully elsewhere.

Thanks are due to the University of New Zealand for financial assistance and to Glaxo Laboratories, Ltd., for their active interest and co-operation in supplying the 1-thyroxine and tri-iodo-thyronine used.

Sulphydryl Groups in Wool

A method for the estimation of sulphydryl groups in hair and other insoluble proteins by means of the specific sulphydryl reagent, 1-(4-chloromercuriphenylazo)-naphthol-2, has recently been reported by Scott and Flesch[1]. In this method, the hair is pulverized, treated with water at 100° or an aqueous solution of a swelling agent at 40° and shaken with a solution of the reagent in amyl acetate, the decrease in concentration of the reagent in the amyl acetate layer being measured colorimetrically.

A modification of this method is in use in this laboratory to detect and estimate sulphydryl groups in wool. The colour reagent is dissolved in formamide, which swells the fibres sufficiently to allow penetration and thus avoids the necessity of grinding up the wool. Sulphydryl groups may therefore be detected by the orange colour of the fibres after washing out excess reagent, and an approximate measure of the concentration of these groups may be obtained by observing the decrease in intensity of colour of a standard solution of the reagent in contact with a known amount of wool. In practice, a sample of 50 mgm. of wool of known moisture content is shaken mechanically at 30° with an appropriate volume of a formamide solution of the reagent containing 4 mgm. per 100 c.c. The rate of reaction is rapid at first, but slows down considerably until after four days it has reached a small, although finite, value. The figures quoted below refer to a reaction time of four days and thus probably represent minimal values. All the untreated wool samples tested so far have become an orange colour, indicating that they contain sulphydryl groups, although samples pretreated with a mercuric chloride solution to block sulphydryl groups do not absorb the reagent.

To standardize the colour reagent, an amyl acetate solution was allowed to react with a known amount of glutathione[2,3]. The solution in formamide could not be used because the coloured derivative of glutathione is soluble in this solvent.

It has been found that, for a typical South African merino wool, the average concentration of sulphydryl groups is 7 micromoles per gm. of dry wool. There do not appear to be any reliable values for the concentration of sulphydryl groups in wool that can be used for comparison (see Park and Speakman[4]).

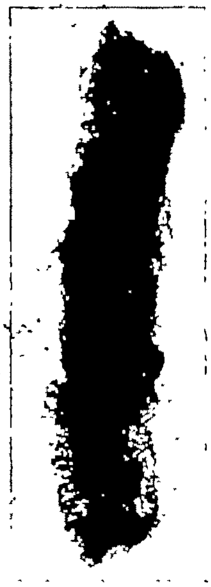

Fig. 1. Light-coloured root section at bottom

The distribution of sulphydryl groups in wool from copper-deficient sheep has been studied by this method. A number of sheep, after having been reared on copper-deficient pasture, were fed a diet adequately supplemented by copper sulphate, as in earlier experiments[2]. Samples of wool were thus available from these sheep with an easily recognizable 'copper-deficient' section and a 'normal' section near the root. Fig. 1 shows such a staple of merino wool after purifying and treating with a formamide solution of the colour reagent for three days. The 'copper-deficient' section has an intense orange colour which tends to decrease towards the tip, possibly owing to the effect of weathering on the sulphydryl groups, and a clear line of demarcation separates this section from the 'normal' section, which has a faint orange colour. The rather short length of the 'normal' section in Fig. 1 was due to felting of this section in formamide.

The average concentration of sulphydryl groups was found to be 26 micromoles per gm. in 'copper-deficient' wool, excluding the damaged tips, and 10 micromoles per gm. in 'normal' wool from the same staple. It is known from the nitroprusside test for sulphydryl groups that the region of intense staining in the wool follicle is of a much greater length in copper-deficient sheep than in normal sheep, although this test gives a barely perceptible colour for 'copper-deficient' wool that has emerged from the follicle[3]. It now appears that the conversion of sulphydryl groups to cystine linkages is less complete in 'copper-deficient' than in 'normal' wool, and this may help to explain the relative weakness of this wool (cf. the results of Palmer[6] on wool hydrolysates).

Experiments aimed at increasing the rate and degree of penetration of the colour reagent into wool fibres are now in progress. It has been found that penetration is complete in a few hours if the fibres are first supercontracted in hot aqueous phenol[7]. In this case, however, about twice as many sulphydryl groups are detected, the origin of which is under investigation.

I wish to thank Dr. P. C. Carman for advice in this work, and the South African Wool Board for a fellowship. This communication is published with the permission of the South African Council for Scientific and Industrial Research.

Pelvic Relaxation in Sheep

Pelvic relaxation in pregnant females has been studied for several species of small animals and for primates[1]. Experimental investigations on the hormonal control of this process in mice and guinea pigs are encountered frequently in the current literature. Less attention has been given to this aspect of reproductive physiology in farm animals. Work is at present in progress at Ruakura on pelvic relaxation in sheep. Study of the factors involved are important in the understanding of parturition problems such as dystocia and vaginal prolapse.

To obtain a clear picture of the physical changes which take place in the pelvic region of the pregnant ewe, sixty animals have been slaughtered. Dissected ewes were examined at monthly intervals during gestation and after parturition. Physical methods were devised to measure objectively changes in the joints and appropriate soft tissues. In these ewes there was no relaxation in the pubic symphysis at any stage. Loosening of the sacro-iliac joints and of the sacro-sciatic ligaments began between the second and third months, reaching a maximum value at, or immediately after, parturition. Regression of these joint changes was incomplete in some cases even three months after lambing. For a total of twenty-five non-pregnant ewes killed just before the breeding season, movement of the sacro-iliac joints was barely perceptible. No loosening of these joints was found in œstrous ewes. It was also found that the sacro-lumbar joint became more flexible with advancing pregnancy. Soft tissues such as those attaching the reproductive tract to the birth canal, and the muscles and ligaments of the perineum, also progressively become 'relaxed', though regression after parturition was much more rapid than in the case of the bone changes. Ewes with vaginal prolapse were generally more relaxed than normal ewes at the same stage of gestation, both in the sacro-iliac joints and soft tissues.

The dissected pelves of two full-term cows and one sow showed relaxation only of the sacro-iliac joints.

In a preliminary experiment on the hormonal control of pelvic relaxation in sheep, four spayed ewes (spayed two years previously) were injected with 10 mgm. of diethylstilbœstrol daily for five days. Two of these ewes were then injected, on the sixth day, with 650 G.P.U. of 'Releasin' (relaxin) (kindly supplied by Dr. Robert L. Kroc, Warner Chilcott Research Laboratories, Morris Plains, New Jersey). All animals, including one untreated spayed ewe, were killed and dissected twenty-four hours later, on the seventh day. In the four treated ewes quite marked loosening of the sacro-iliac joints and the sacro-sciatic ligaments occurred, equivalent to that found in ewes four months in lamb. The joints of the relaxin-treated ewes were no looser than those injected with stilbœstrol alone. No measurable changes took place in the soft tissues.

Investigations have shown that œstrogen and androgen can first be detected in the urine between the twelfth and fifteenth weeks of gestation[2], providing indirect evidence that hormones are closely involved in pelvic relaxation in the ewe.

In the experiment on spayed ewes described above, loosening of the sacro-iliac joints was caused by œstrogenic stimulation alone. However, further work is necessary to study the role of the relaxin hormone. Preliminary experiments have shown that a substance with relaxin-like activity is present in pregnant ewes' ovaries, and in very low concentrations in the blood serum. Interaction of oestrogen and relaxin may be necessary to effect marked changes in soft tissues at different dose-levels than those used here.

The mode of action of relaxin appears to vary markedly between different species. There is room for extensive study of the comparative physiology of this hormone.

Tolerance to the Maize Rust *Puccinia polysora* Underw.

THE maize rust disease *Puccinia polysora* Underw was observed in Nyasaland again in the 1953–54 growing season, its first appearance in the country having been in the 1952–53 season. At the Agricultural Research Station, Lilongwe, a replicated trial was carried out in which the use of a fungicide spray 'Blitane' (zinc ethylene *bis* dithiocarbamate) reduced the incidence of the fungus on the maize on sprayed plots as compared with those which were unsprayed. All plots were split into three varieties: (*a*) an imported hybrid; (*b*) a locally selected open-pollinated variety; (*c*) an unselected local native maize.

Scores were made for the number of open uredosori, the total possible for a severely infected plant being 9. Spraying did not prevent the incidence of the rust, but reduced the score for the sprayed plots by about one half as compared with those unsprayed. The unsprayed hybrid was given an average score of 3·5 per plant, and those of the local selected and unselected maize were 1·9 and 1·6 respectively. However, the yield of the hybrid was reduced by 17 per cent, whereas that of the local varieties was completely unaffected. Thus there are clear indications of differences in varietal susceptibility and of tolerance, although all three types have given the fully susceptible reaction to the method of testing for juvenile resistance in the greenhouse.

The tolerance of the local varieties—which yielded much less than the hybrid even when the latter was fully attacked by the rust—may be an indication that they do not express in the yield of their grain the full capabilities of their metabolism. This would allow for a reservoir which absorbs the inroads of disease, and until it is exhausted no loss in yield would be encountered. Native maize of this same type has been inbred, and hybrids produced, which will be grown here next season. If the foregoing hypothesis is correct, it may be expected that these, being more highly selected and yielding more nearly to their true capacity, will suffer greater loss in yield from the presence of the disease.

A Method of rearing Individual Trombiculid Mites in the Field

THE taxonomy of the Acarina Trombiculidae requires stabilizing by the study of the non-parasitic post-larval stages. Fewer than sixty nymphs and adults are known out of more than five hundred species, and of these only very few can be identified with absolute certainty. Techniques for rearing nymphs from engorged larvæ are widely known and practised, but a single host often carries several or many species of chiggers, and taxonomic studies make it necessary to identify each nymph by reference to the cast larval pelt. Although this is practicable in the laboratory, it is extremely difficult to do in the field especially when moving from place to place, because nymphs may take several weeks to emerge.

The following simple method was designed to allow the rearing of identifiable nymphs from chiggers collected during expeditions in Borneo and Malaya. It has also been used for rearing nymphs of related families of mites. It is worth noting that the larval pelts obtained are frequently complete except for disarrangement and some loss of body setæ; and because they show no deterioration with age after mounting they are often of more permanent value than mounts of actual larvæ themselves.

Collection of engorged larvæ. Techniques must be modified for every occasion to suit local conditions and requirements, such as the need to preserve skins of hosts intact. It is economical to allow chiggers to become detached naturally rather than to pick them off individually. Scrapings, or better, fragments of infested skin, are placed in water in cavity blocks, or are pinned to the corks of 2 in. × 1 in. tubes, and left overnight for larvæ to become detached. Engorged larvæ are then selected for rearing. Full engorgement is not always necessary to allow development of the nymph. If time and space allow (for example, in the laboratory), chiggers may be placed on water in cavity blocks or Syracuse dishes and the emergence of nymphs awaited—the nymph usually sinks while the larval pelt remains floating.

Rearing in tubes. Use stout round-bottomed tubes, or simple lengths of tubing corked at both ends, and soft rubber corks; a good size is about 35 mm. × 8 mm. Cut cigarette paper into strips to fit the tubes, say, 25 mm. × 6 mm. When planting larvæ, mark a small circle in pencil near one end of a strip, at the same time entering identification data and date. Place in a tube with the circle near the mouth and wet thoroughly. Plant a selected larva in the marked circle: it is usually held there by surface tension, and the optimum degree of wetness is soon learnt by experience. Flooding will allow the larva to move within the water film; if the size of the paper and the amount of water added is too small in relation to the volume of the tube, the paper will tend to dry out and the larva be released. Most papers have too rough a surface and hold too thick a film of water to be suitable. If conditions of work allow, it is better to allow batches of larvæ to remain floating in water in cavity blocks for a few days and then to plant out the larvæ which become akinetic. The corked tubes are inspected at intervals. When a nymph has emerged, it should be preserved in 50 per cent spirit together with identification data. The larval pelt is usually left stuck down by the water film in the circle on the paper slip; it can be floated off gently at leisure and mounted. It can nearly always be identified without trouble, but it helps to have mounted a batch of larvæ from the same host. If fungal growth proves troublesome, it may be kept down by a trace of merthiolate. This is preferably introduced after the larva has become akinetic. It, or a trace of formalin or spirit, may be introduced as a routine to the tube after removing the nymph if the larval pelts are to be kept indefinitely awaiting an opportunity to mount and study them. The comments of other workers who use this technique would be greatly appreciated.

Presence of a Peritrophic Membrane in Diplopods

The presence of a peritrophic membrane has been reported in the midgut of the following classes of mandibulate Arthropoda: Onycophora, Crustacea, Insecta and Chilopoda[1]. It has not been reported in the Diplopoda, although Randow[2] stated that the brush border of the midgut epithelial cells may slough off. We have dissected tubular membranes giving a positive chitosan reaction[3] from the midguts of the following British millipedes: *Tachypodoiulus niger*, *Ophyiulus pilosus*, *Iulus scandinavius*, *Cylindroiulus punctatus* (Iulidae), *Glomeris marginata* (Glomeridae), *Polydesmus angustus* (Polydesmidae), *Polymicrodon polydesmoides* (Craspedosomidae) and *Choneiulus palmatus* (Blaniulidae). The presence of a similar membrane has been inferred from paraffin sections of the midgut of *Polyxenus lagurus* (Polyxenidae). In none of these is there an œsophageal valve; it is therefore inferred that the peritrophic membrane arises by delamination of the brush border from the midgut epithelial cells. A delaminating brush border has been observed in *O. pilosus*, *C. punctatus*, *G. marginata*, *P. polydesmoides* and *C. palmatus*. Furthermore, in *G. marginata*, *P. angustus*, *T. niger*, *I. scandinavius*, *C. punctatus* and *P. polydesmoides* concentric peritrophic membranes were seen in sections, a phenomenon often observed when membranes are formed by delamination[4].

We wish to thank Mr. J. G. Blower for his help with identifications.

Acceleration of Flowering in Non-vernalized Chrysanthemums by the Removal of Apical Sections of the Stem

Vince and Mason[1] have reported recently that unvernalized plants of *Chrysanthemum morifolium* var. Sunbeam can be induced to produce flowering lateral shoots by decapitation of the main shoot. Under the stated conditions the main apex did not bud for a further four to six weeks. They suggest that inhibitory effects from the main apex are responsible for the failure of unvernalized plants to bud.

However, in variety Sunbeam it is in fact quite unnecessary for the main apex to be removed in order to obtain budded laterals. This observation was briefly mentioned in the paper referred to by Vince and Mason[2].

Flowering laterals in the presence of a vegetative main apex frequently appear on plants that have received a slight degree of vernalization. In a recent experiment, four out of four slightly vernalized plants, and twelve out of twenty-four incompletely devernalized plants which failed to bud with their main apices, produced flowering lateral shoots. The entirely unvernalized controls remained vegetative at lateral as well as main apices. A photograph of such plants accompanies a manuscript awaiting publication in the *Journal of Experimental Botany* dealing with the de-vernalization of the chrysanthemum.

As regards the theoretical interpretation of Vince and Mason's results, it may be mentioned that no evidence has been found for translocation of either positive or negative effects in grafting experiments between vernalized and unvernalized partners[3].

Zoological Nomenclature

NOTICE is hereby given that, as from April 22, 1955, the International Commission on Zoological Nomenclature will start to vote on the following cases involving the possible use of its plenary powers for the purpose specified against each entry. (1) Renier [1804] *Prospetto*; question of validation of four generic names (*Discoides*; *Cerebratulus*; *Polycitor*; *Scolizedon*) published in; (2) Renier [1807] *Tavola*; question of validation of six generic names (*Aglaja*; *Alcyonaria*; *Cystia*; *Rodens*; *Tuba*; *Tubulanus*) published in; (3) names (generic and specific) given to aptychi of Ammonites, suppression of; (4) *Notropis* Rafinesque, 1818 (Cl. Osteichthyes), determination of gender as masculine; (5) *Cheloniceras* Hyatt, 1903 (Cl. Cephalopoda, Order Ammonoidea), designation of type species for; (6) *Argus* Bohadsch, 1761 (Cl. Gastropoda), retention of status for the purposes of the law of homonymy, to preserve *Lysandra* Hemming, 1933, from falling as a synonym of *Argus* Boisduval, 1832; (7) *minimus* Miller (J. S.), 1826 (*Belemnites*) (Cl. Cephalopoda, Order Dibranchia), validation of. A proposal for a 'Declaration' banning names based on aptychi of ammonites is also being made.

Full particulars of these cases appear in Part 9 of Volume 9 of the *Bulletin of Zoological Nomenclature*.

Comments on the above cases should be sent to me as soon as possible.

FRANCIS HEMMING
(Secretary)

28 Park Village East,
Regent's Park,
London, N.W.1.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, November 29

British Society for the History of Science (in the Lecture Theatre of the Science Museum, South Kensington, London, S.W.7), at 5.30 p.m.—Dr. G. J. Whitrow: "Ancient and Mediaeval Hindu Mathematics and Astronomy".

Tuesday, November 30

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. B. A. Rowley: "Psychology and Literary Criticism".*

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. A. D. Holland: "Prestressed Units for Short-Span Highway Bridges".

Royal Institute of Chemistry, London Section (joint meeting with the Sir John Cass College Chemical Society, at Sir John Cass College, Jewry Street, London, E.C.3), at 6.30 p.m.—Dr. M. A. Phillips: "Synthetic Organic Chemicals in Agriculture".

Society for Analytical Chemistry, Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Tenth Annual General Meeting, followed by a discussion on "Possibilities in the Establishment of Standard Samples for the Determination of Some Trace Elements".

Wednesday, December 1

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Prof. J. N. Davidson: "Recent Developments in the Biochemistry of the Nucleic Acids".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. J. N. Dean: "The Insulation of Submarine Telephone Cable" (Llewelyn B. Atkinson Memorial Lecture).

Institution of Electrical Engineers, Radio Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. H. Page and Mr. G. D. Monteath: "The Vertical Radiation Patterns of Medium-Wave Broadcasting Aerials".

Society for Analytical Chemistry (joint meeting with the Oils and Fats Group of the Society of Chemical Industry, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Meeting on "Methods for the Chemical Determination of Vitamin A".

Society of Visiting Scientists Limited (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion Meeting on "Recent Research on Speech". Chairman: Sir Archibald Gill; Speakers: Dr. D. B. Fry, Dr. E. C. Cherry and Prof. R. C. Oldfield.

Wednesday, December 1—Thursday, December 2

Iron and Steel Institute (in association with the Institute of Metals, at Church House, Westminster, London, S.W.1)—Symposium on "Powder Metallurgy".

Wednesday, December 1

At 9.45 a.m.—Discussion on Papers in Group 1: "Manufacture, Properties and Testing of Powders".

At 2.15 p.m.—Discussion on Papers in Group 2: "Principles and Control of Compacting and Sintering".

Thursday, December 2

At 9.30 a.m.—Discussion on Papers in Group 3: "Manufacture and Properties of Structural Engineering Components".

At 2 p.m. Discussion on Papers in Group 4: "Powder Metallurgy of High-Melting-Point Materials".

Thursday, December 2

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. A. J. Arkell: "The Magical Statuettes of Ancient Egypt".*

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. J. Grenfell Williams: "Broadcasting in the Colonies".

University of London, British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. Rosalind Pitt-Rivers: "Thyroid Hormones". (From a series of lectures on "The Scientific Basis of Medicine".)*

Society of Chemical Industry, Road and Building Materials Group (in the Lecture Hall of the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Mr. D. C. Broome: "The Physico-Chemical Properties of Bitumens as used in Mastic Asphalt".

Institute of Metals (joint meeting with the Chemical Engineering Group of the Society of Chemical Industry, at the University Chemical Department, Woodland Road, Bristol), at 6.30 p.m.—Dr. A. R. Harding: "Thermochemistry of Alloys".

Institute of Physics and the Chemical Society (joint meeting of the Manchester Branches, in the Chemistry Lecture Theatre, The University, Manchester), at 6.30 p.m.—Prof. P. J. Flory (Cornell University): "The Configuration and Properties of Polymer Molecules in Dilute Solution".

British Glaciological Society (at Bedford College, Regent's Park, London, N.W.1), at 7.30 p.m.—Mr. H. Lister: "The Glaciological Work of the British North Greenland Expedition".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Friday, December 3

British Society for the History of Science, Philosophy of Science Group—Northern Branch (in Staff House, The University, Manchester), at 7 p.m.—Dr. W. H. Thorpe, F.R.S.: "The Study of Animal Behaviour and Some of its Implications".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Christopher Hinton, F.R.S.: "Industrial Power from Nuclear Energy".

Saturday, December 4

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. Eric Simms: "A Study in Sound of Some Highland Birds".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer or Assistant Lecturer in Clinical Parasitology in the Veterinary School—The Registrar and Secretary, The University, Bristol (November 30).

Assistant Experimental Officer to work in the Bee Department on bee behaviour—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (December 1).

Research Assistant in the Department of Physics, for duties which will involve general assistance in radio research investigation—The Registrar, University College, Singleton Park, Swansea (December 1).

General Assistant Engineers (2), (with a university degree or equivalent qualifications in electrical engineering or in physics) at the Research Laboratories, British Electricity Authority, Leatherhead, for duties which include research on electrostatic precipitation and allied problems—The Director of Establishments, British Electricity Authority, Winsley Street, London, W.1, quoting NAT/541 (December 3).

Pathologist (with veterinary or medical qualifications) at the Poultry Research Centre, Edinburgh, to develop a programme of original research using the fowl as experimental material—The Secretary, Agricultural Research Council, Cunard Building, 15 Regent Street, London, S.W.1 (December 3).

Biochemist, basic grade (with a B.Sc. degree with honours in biochemistry or chemistry, or equivalent qualification)—The House Governor, The General Hospital, Birmingham 4 (December 4).

Head (with a good honours degree, teaching and industrial experience, and preferably with research experience) of the Engineering Department—The Principal, Kingston Technical College, Fassett Road, Kingston-upon-Thames (December 4).

Principal (with a degree in agriculture and sound practical farming knowledge, experience of teaching and administrative ability) of the Brooksby Hall Farm Institute—The Director of Education, County Offices, Grey Friars, Leicester (December 4).

Research Student (graduate in physics or electrical engineering) in Physics—The Registrar, The University, Sheffield (December 6).

Scientific Officer (honours graduate) to carry out ecological and population studies of soil pests as affected by insecticides—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (December 8).

Lecturer or Senior Lecturer (with an appropriate honours degree and preferably with teaching experience) in Mathematics, and Physics and Mechanics, at the R.N. College, Dartmouth—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting 4397/54 (December 10).

Physicist (with H.S.C. (science) or equivalent) in the Ministry of Supply, to assist in environmental physiological research in Nigeria—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.325/54A (December 11).

Professor (with high academic qualifications and practical works experience in ferrous metallurgy) of Chemistry and Metallurgy, at the Royal Naval College, Greenwich, London, S.E.10—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting 4396/54 (December 14).

Assistant (graduate in science, preferably biochemistry or organic chemistry, and with research and literary experience) to the Chairman of the Editorial Board—Dr. A. Neuberger, F.R.S., *Biochemical Journal*, National Institute for Medical Research, The Ridgeway, Mill Hill, London, N.W.7 (December 18).

Research Officer (Bacteriologist) (with an honours degree in science or agricultural science with bacteriology, chemistry or biochemistry as a major subject, and with postgraduate research experience) in the Division of Food Preservation and Transport, Commonwealth Scientific and Industrial Research Organization, Homebush, N.S.W., Australia, for investigations in the field of microbial physiology; initially studying the effects of freeze-drying—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 300/150 (December 18).

Senior Research Fellow (with experience in wind-tunnel work) in the Department of Aeronautical Engineering, to design new high-speed laboratory equipment and take a leading part in the research work of the Department—The Secretary and Registrar, The University, Southampton (December 31).

Chair of Pharmaceutical Chemistry—The Registrar, The University, Nottingham (January 8).

CHAIR OF PHYSICAL METALLURGY—The Registrar, The University, Sheffield 10 (January 8).

I.C.I. RESEARCH FELLOWSHIPS IN BIOCHEMISTRY, CHEMISTRY, ENGINEERING, PHARMACOLOGY or PHYSICS—The Secretary of University Court, The University, Glasgow (February 26).

ASSISTANT, Grade B (graduate of a British university, and with good teaching and/or industrial experience) to teach chemistry in relation to the cocoa, chocolate and sugar confectionery industry; and an ASSISTANT, Grade B (graduate of a British university, and with good teaching and/or industrial experience) to teach biology up to general certificate of education advanced level—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

ASSISTANT (Scientific) IN THE METROPOLITAN POLICE LABORATORY—The Secretary, Room 139, New Scotland Yard, London, S.W.1.

BIOCHEMIST, CHEMIST or PHYSICIST (interested in research in biophysics), to join a small team studying the structure of plant viruses—The Secretary, Birkbeck College, Malet Street, London, W.C.1.

CHEMIST (with considerable experience in the analysis of biological materials, and, in particular, the use of modern techniques, and able to assist in equipping and organizing a new laboratory unit) to take charge of the Analytical Department—The Secretary, Grassland Research Institute, Hurley, near Maidenhead, Berks.

ELECTRICAL ENGINEER/PHYSICIST, Senior Experimental Officer grade (with at least H.S.C. (science) and preferably with a good basic understanding of electronics and practical experience of the generation of high voltage pulses and the measurement of very short time intervals) at Fort Halstead, Kent, to assist in research and development on problems associated with high voltage, high energy electrical discharges—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 290/WGH/2.

ENTOMOLOGIST, PLANT BREEDERS (2), and a SOIL CHEMIST (with an appropriate honours degree, and fully literate in either Arabic or English) in the Research Division of the Ministry of Agriculture, Sudan Government—The Sudan Agent, Sudan House, Cleveland Row, London, S.W.1.

ENTOMOLOGIST, to develop a field technique to control biting midges—Dr. S. D. Kettle, Zoology Department, West Mains Road, Edinburgh 9.

EXPERIMENTAL OFFICERS (3) (with at least Higher School Certificate in science subjects or equivalent) IN THE NUCLEAR PHYSICS DIVISION for research in the study of nuclear transmutations—The Establishments Officer, United Kingdom Atomic Energy Authority, Research Group, Harwell, Didcot, Berkshire, quoting 2/103/181.

PHYSICIST/MECHANICAL ENGINEER, Scientific Officer grade (with a first- or second-class honours degree in physics or equivalent qualification) to undertake studies/research on the mechanical effects of stresses applied to atomic weapons (Ref. 109/WGH/2); and a PHYSICIST or METALLURGIST, Scientific Officer grade (with a first- or second-class honours degree in physics or metallurgy) to carry out fundamental and applied research on reactive inorganic compounds (Ref. 251/WGH/2)—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting appropriate Ref. No.

PRINCIPAL SCIENTIFIC OFFICER (with a first- or second-class honours degree or equivalent in physics, mechanical or electrical engineering, and with considerable research experience) IN THE ROCKET PROPULSION DEPARTMENT, R.A.E., Westcott, Bucks, to lead a small section engaged in research and rocket motor instrumentation—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.321/54A.

RESEARCH OFFICER (with a first- or second-class honours degree in biology and at least two years postgraduate experience in animal genetics) IN THE EAST AFRICAN AGRICULTURE AND FORESTRY RESEARCH ORGANIZATION, for animal genetics studies in the Animal Industry Division—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.196/151/01.

SCIENTIFIC OFFICER (with a first- or second-class honours degree in physics or equivalent qualification) for basic research into the mechanical properties of certain radioactive metals and alloys—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 272/WGH/2.

SCIENTIFIC OFFICER (with a first- or second-class honours degree in physics or mathematics, and an interest in applying mathematics to practical problems) to carry out theoretical work in connexion with the design of nuclear reactors—United Kingdom Atomic Energy Authority, Research Group, Harwell, Didcot, Berks.

SENIOR BIOCHEMIST (science graduate)—The Medical Superintendent, County Hospital, Stonehouse, Lanarkshire.

SENIOR SCIENTIFIC OFFICER or SCIENTIFIC OFFICER (with a first- or second-class honours degree in physics with subsidiary mathematics, and for the post of Senior Scientific Officer at least three years appropriate postgraduate research experience) at Fort Halstead, Kent, to undertake experimental small-scale work on fundamental problems in connexion with the study of phenomena associated with explosions—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 209/WGH/2.

TECHNICIAN (preferably with experience in a pharmacological or physiological laboratory) IN THE DEPARTMENT OF PHARMACOLOGY—The Secretary, University College, Gower Street, London, W.C.1, quoting Pharmacology/5.

THE UNIVERSITIES AND THE COMMUNITY

In recent months there have been many discussions, lectures and even books on the purpose and function of universities. These institutions, many of them of venerable age and with long traditions, have had to meet changing conditions, and are indeed successfully adapting themselves to the needs of the times. In that process, however, they need all the support which an enlightened public opinion can give them.

A recent book in this field, Dr. Robert M. Hutchins's "The University of Utopia", is particularly interesting and has already been mentioned in these columns. Dealing with the hazards to education arising from industrialization, Dr. Hutchins makes it clear how serious may be the consequences of any narrow view of education, even at the technical, let alone the university, level. He fully recognizes the difficulty of making work significant in an industrial, mechanized economy. None the less, he maintains, like Mill, that the true strength of a democratic society lies in the character of its citizens. Indeed, there is much in his book that is relevant to the debate on university entrance requirements raised by the pamphlet recently issued by the Joint Matriculation Board. That pamphlet, affirming a belief in the value of the broad-based entry, argues that without the protection which such an examination affords, the schools, and especially the smaller ones, would be exposed to the narrowing influences of vocational demands, which could not easily be resisted.

There is much support for this argument; but whatever the decisions as to where the basis of education is to be broadened, it should not be taken without a clear conception of what is involved. Like the Utopians described by Dr. Hutchins, we should first ask ourselves what it is we are trying to do, and have regard not merely to the vocational demands but also to the implications of education for leisure and the purpose of university education, before we prescribe its content. We must, as Sir Charles Morris emphasized last spring in his Joseph Payne Memorial Lectures on "The Idea of University Education" (published in the *Universities Quarterly* of August and November 1954), recognize that there are limits to what a university can give in the short span of a student's life at a university. Moreover, if for the reasons which Dr. Hutchins, A. N. Whitehead, Sir Charles Morris, Sir Hector Hetherington and others agree in giving, a university is not concerned to impart a stock of information or of tricks of some specialized trade, we must be quite clear as to what a university should seek to give its students by way of preparation for their future careers.

It is by the influence that it exerts upon the subsequent lives of action of its graduates that university education will be mainly judged, as Sir Charles Morris rightly remarks; and the answer he gives to the question what can the university do to encourage the development of the faculties and capacities by which young people will be able to make the judgments necessary for their actions and decisions if they are to serve their generation as rational, educated men and women, is first and foremost that it should impart a sturdy faith in the power of reason in human affairs. It may be taken for granted that personal contact between teachers and taught, as well as between students—which not only makes for education in living but also contributes to the ability to communicate with others—is no less important than the grasp of fundamental ideas. Further, the faith in the power of reason and the ability to communicate with others are not only the essentials of an educated man or woman; they are equally the conditions for the survival of democratic society.

It follows, therefore, that if the universities put first things first and are really carrying out their educational responsibility, they are once again making their protest against the isolation of man from man of which John Richard Green wrote, and they will at the same time renew that contact with the world outside which Mansbridge stressed as so important when he was writing of the older universities. In serving this ideal, the variation in method between university and university in the pursuit and exposition of knowledge for its own intrinsic sake may be quite immaterial. Indeed, as Sir Ernest Barker has commented, poor accommodation may often be a spur to good education; at least it is no obstacle in inculcating the habit of learning.

But it must be remembered that a university is also a home of learning, a place where our inheritance of knowledge is increased and kept alive—a place, in Whitehead's words, for the imaginative acquisition of knowledge. Sir Charles Morris, pointing to the achievements of recent years, remarks that imagination cannot have been entirely atrophied in the specialist of to-day in his youth; but none the less, he wonders whether specialized success is to some extent being bought at the cost of starvation of the imagination and of *élan*. Certainly that is a danger to which the university teacher could easily be exposed, both through outside pressure and a general failure to understand the purpose of a university, and through confusion as to the proper place of research in the work of a university.

While, however, the vigorous quest for new knowledge is necessary to maintain the vitality of university teaching, it is less certain that the dedicated research worker benefits by giving up some of his energy in teaching; and there can be no doubt at all that many students who are induced to undertake research neither profit by it themselves nor obtain results of high importance in their investigations. Without restricting entry to a university to anything like the extent which characterizes the University of Utopia described by Dr. Hutchins, or transferring to other institutions, such as the colleges of technology, much of the vocational education or training at present given in British universities, it would still seem worth while to reconsider the place of research in university work. While ensuring full opportunity for research for the university teacher, it might be wise not to encourage the undergraduate and postgraduate student to take up research, unless he shows distinct promise of contributing to knowledge or benefiting significantly by such activities. Even for the university teacher, it is as well to remember Dr. Hutchins's caution as to the importance of reflective thinking. What a university teacher or student needs above all is time for reflexion: when other activities, no matter what they are, leave the teacher or student no time for serious thinking, the university is missing its mark.

Here, as in discussing the educational function of the university, Dr. Hutchins's message for the British reader is a warning of the importance of maintaining standards. There is little reason for thinking that British universities are in any grave danger of making excessive concessions to vocational training, though the warning is one to be kept in mind, particularly in planning the expansion of technological and of technical education. Narrowness of mind, inability to take broad views and obtuseness in handling other men are more likely to arise from over-specialization in school, and the preoccupations caused by extra-mural pressures may well limit the ability of the university to correct such defects or tendencies within the span of three academic years. None the less, the warning is timely, and the way in which Dr. Hutchins sets his University of Utopia, not merely at the apex of the educational system but also against the social background, reminds us that the success with which the universities pursue and impart learning with imagination, breadth and vision depends not on themselves alone, but on the co-operation of the schools and the understanding and support of public opinion. Where support is withheld, and lack of understanding circumscribes the activities of the university and infringes its freedom of investigation and discussion, the lighted torch burns dim. It can only be handed on flaming strongly when the purpose and functions of the university are clearly understood and strongly upheld by the community of which the university is part.

DESIGN OF STEEL BUILDING FRAMES

The Steel Skeleton

By Prof. J. F. Baker. Vol. 1: Elastic Behaviour and Design. Pp. xi+206+4 plates. (Cambridge: At the University Press, 1954.) 42s. net.

THIS is the first volume of a new two-volume work by Prof. J. F. Baker on the scientific study and logical design of the steel building frame. The second volume, yet to appear, will deal with the plastic behaviour of the structure and will, without doubt, be the more eagerly awaited part of the work. The present volume is largely historical in its content. It shows, step by step, how the logical attack on the problem developed, and what stage has now been reached in the study of the elastic behaviour of the steel frame. The first nine chapters describe the activities of the Steel Structures Research Committee in its seven years of active investigation (1929–36) of stresses in building frames. The necessity of such repetition of published work might well be questioned, but justification lies in the fact that, after the bombing of the Second World War, relatively few of these reports were in existence.

The Committee, of which Prof. Baker was technical secretary, found the conventional, simple method of design to be irrational and inexact. As a result of many tests on existing buildings, on a specially constructed frame, and on laboratory specimens, a new and rational method of design was devised. This method is, once more, described by Prof. Baker. In 1936 when it was first put forward as a solution to the problem of the steel frame, designers found it complex and time-consuming, and discovered also that there was no significant economy in the amount of material used. The semi-rigid steel skeleton was also sensitive to settlement and to variations in workmanship and materials, and the new recommendations were ignored.

Perhaps Chapter 14, "The Reception of the Recommendation", with its closely argued and critical review of the attempts made to guide the designer of steel frame, is the part of the book which carries the most vital lesson for the engineer. The first publication of the Steel Structures Research Committee (1931) comprised a "Code of Practice for the Use of Structural Steel in Building". This was meant to be of temporary assistance to engineers until the results of research could be made public. It was based, as all codes of practice tend to be, on current practice. It looked back while the Committee looked forward. In spite of that, its terms were embodied in London County Council regulations and in British Standards Specification 449, and it controlled the design of steel frames in Britain until 1948.

After the tacit rejection of the Committee's research by the disregard paid to its recommendations, a further attempt was made by a joint committee of the Institution of Civil Engineers and the Institution of Structural Engineers to draw up a revised code of practice which would be more acceptable to the profession and yet embody much of the new knowledge as yet unused. A war-time Steel Structures Committee supported this revised code of practice.

Coming nearer the present day, Prof. Baker describes the new British Standard 449 of 1948. The new Standard describes both semi-rigid and fully-rigid design methods—the first official encouragement for the rational methods reported in 1936. The revision, however, does not constitute a real acceptance of the ideas of the Steel Structures Research Committee, and Prof. Baker sees in B.S. 449–1948 a potential if not a present danger. The B.S.S. 449 of the 1930's showed the current practice; the Committee pointed the way to the future. B.S. 449–1948 is neither based on long-established practice nor firmly on the Committee's findings. It has taken a step in an unknown direction. When this Standard comes up for revision, Prof. Baker fears a further step 'over the edge'.

We are now approaching the nineteenth year since the behaviour of the steel skeleton in the elastic field was first defined, and logical answers given to design problems. At the Building Research Congress in 1951 there were signs that the designer is still searching for an answer to these problems and perhaps inclined to look at the views of the Steel Structures Research Committee. This volume, with its wealth of scientific results and deductions and its history of a rather unhappy and confused chapter in the history of structural engineering, comes as a salutary lesson. Prof. Baker, perhaps unnecessarily kind to the reader, makes the confusion of codes and recommendations less confused by omitting all reference to Code of Practice 113 which appeared at about the same time as B.S. 449–1948, and conflicted with it in a way which did no credit to the co-ordinating ability of engineers. The designer can learn much from this book—much of technical value in his work and much of the gulf which still exists between the scientific research worker pushing ahead in new fields and the so-called 'practical' man, too often afraid to adventure where the man of science has trod.

As a minor criticism it should be noted that the British Standards Institution abandoned the use of the word "Specification" some years ago. Its publications are "British Standards". Finally, why should this volume be 10¼ in. high? It will be a physical embarrassment to shelves adjusted to other 'structural' publications. W. FISHER CASSIE

HONEYBEES AND THEIR ACTIVITIES

The World of the Honeybee

By Dr. Colin G. Butler. (The New Naturalist: a Survey of British Natural History.) Pp. xiv + 226 + 42 plates. (London: William Collins, Sons and Co., Ltd., 1954.) 21*s.* net.

RECENTLY a church window has been dedicated to the Rev. Charles Butler, whose famous book the "Feminine Monarchie" appeared a little less than 350 years ago (in 1609). It is a pleasure to review a contemporary book by his namesake, and one is tempted to begin with a comparison between the two books, which encompass modern progress in our knowledge of the ways of the honeybees. Thus the older Butler's discovery that not the queen but the drone is the male bee is now generally accepted, but his assumption that drones and workers mate and the latter lay eggs has been refuted. His opinion that the workers "by this sense [of smell] find out any strange bee, which is not otherwise to be known from his own company", has after several decades of disbelief been verified and amplified by recent experiments. Altogether, it appears that progress was made by controlled experiments rather than by observation alone.

Dr. Butler's comparative and evolutionary approaches to such subjects as social organization in general and to more special topics like swarming and communication are, of course, modern features.

The author's recently published discovery of a 'queen substance' and of some of its properties form the book's most original part. This somewhat fugitive substance may be a part of the waxy covering of the queen's body, or more probably of the volatile solvent in which the wax is believed to be secreted. A small number of the workers of a colony obtain queen substance by licking the body, particularly the abdomen, of their queen and then offer food to other members of their colony, thus widely distributing some of the substance. So long as sufficient queen substance is in circulation, the bees of a colony are as a rule in a state of organized activity. But when the queen is lost or becomes enfeebled, disorganized restlessness ensues, sometimes after a few minutes, and regulatory processes like the building of emergency queen cells, the transplantation of young larvæ or supersedure are observed after a few hours or days. On the other hand, supernumerary queen cells or young virgin queens, which are ordinarily destroyed, are then tolerated. A large colony of bees needs more queen substance than a small colony, and it is probably the relative scarcity of this substance which results in the production and toleration of the young queen and thus in swarming.

The work of other bee-workers which Dr. Butler has incorporated in the text is necessarily restricted, but the emerging picture is on the whole correct and well balanced. An error concerning the sun orientation of bees occurs on p. 199; experiments by Wolf apparently demonstrating that bees trained to a feeding place in sunny weather and afterwards caged and kept there for an hour return in a wrong direction, as the sun had moved on, are probably wrong. More recent experiments by Meder, referred to by v. Frisch in 1952, indicate that captive bees—like any other bees, but unlike ants—take the daily movement of the sun into account when they use it for orientation.

The author is to be congratulated on the exquisite photographs—eighty-seven in black-and-white and two in colour. For readers whose appetite has been whetted, a list of books is furnished where references to the original literature and the description of research techniques can be found. There are author and subject indexes. H. KALMUS

LOGARITHMETICA BRITANNICA

Logarithmetica Britannica

Being a Standard Table of Logarithms to Twenty Decimal Places of the Numbers 10,000 to 100,000. By Dr. Alexander John Thompson. Vol. 1: Numbers 10,000 to 50,000, together with a general introduction. Pp. xcviii + Tables. Vol. 2: Numbers 50,000 to 100,000. Pp. iv + Tables. (Issued by the Department of Statistics, University College, London, to commemorate the tercentenary of Henry Briggs' publication of the *Arithmetica Logarithmica*, 1624.) (Cambridge: At the University Press, 1952.) £8 8*s*. net the set.

THE invention of logarithms by John Napier and the introduction of the number 10 as base by Henry Briggs have led to tables which have been of inestimable benefit to computers for three centuries. Many hands and very many years were needed, however, before tables known to be completely accurate became available. During this period, also, tables were given to fewer and fewer decimals, culminating in the familiar tables to four, five or six decimals that are in everyday use. This is, in fact, one of the means by which accuracy was ensured—by concentrating on fewer figures.

It is true that the growing use of calculating machines has diminished the need for logarithms among professional computers, but many remain who use them for preference or because other equipment is inaccessible; these workers mainly need relatively few figures.

The logarithm also has other users among computers, for it remains a function in its own right, and has applications quite apart from its employment as a method for converting multiplication to addition, and easing other calculations. Certainly, as a function in analysis it is the natural logarithm, to base e, which arises alongside exponential, circular and hyperbolic functions; but the relation between the two is simple, and evaluation for an arbitrary argument is rather more easily carried out with common logarithms. There exists, then, a need for a fundamental table of logarithms, which shall be definitive, in that it should be completely accurate, and should have a number of figures adequate for all needs which may be reasonably expected, and should, moreover, be easy to interpolate.

In the tables under review, A. J. Thompson meets this requirement for a definitive table in a remarkable manner. The only other tables of comparable extent—giving the logarithms of a hundred thousand numbers or more—whether to base e or base 10, have fifteen decimals only, and none of these makes full provision for interpolation by differences. Thompson, in his tables, gives twenty-decimal logarithms of all integers to 100,000, together with second and fourth differences—all that are needed for interpolation. The introduction discusses very fully the various ways in which interpolation can be effected, and is a mine of information. It is not stated there that δ^4 can be dispensed with from about 23,000 onwards, by replacing δ^2 by $\delta^2_m = \delta^2 - 0{\cdot}184\delta^4$, the "modified difference" of Comrie; but it is only fair to mention that Thompson has a strong dislike of *ad hoc* methods of this nature.

To the initiated there is little need to defend the twenty-decimal accuracy in a fundamental table, but it may be worth while to state reasons for welcoming such a choice. Makers of fundamental tables have to carry out exploratory calculations in preparing tables to eight- or ten-figure accuracy which will later form a basis for accurate tables to fewer figures. In these exploratory calculations it is very common to meet a quantity as the difference of two others which may agree to three, five or even ten figures. This is certainly a challenge to the mathematician to find an expression for the difference directly; but, while devising this, he does not want to be held up by being unable to get a value at all in the meantime. Again, in step-by-step processes, errors may accumulate rapidly, or even grow exponentially—another challenge, but often avoided by using extra figures when to accept the challenge involves side-tracking; the use of the recurrence formula for the Bessel function $J_n(x)$ provides an example of this. These two reasons alone, occurring week by week over centuries, provide an adequate justification for tables like the present one.

This table was conceived originally as a tribute to the memory of Henry Briggs and the first part was published in 1924, the tercentenary of the publication of Briggs's "Arithmetica Logarithmica". The ninth and last part to be published appeared in 1952, and the whole work is a monument, which will last, to the effort and perseverance of one man. Thompson set out to explore the possibility of preparing a table which could be interpolated by means of even central differences with Everett's formula. He found that he needed to design a calculating machine, illustrated opposite p. lv of Vol. 1, to make reasonably possible the computation of logarithms by summation from fourth differences. When he had prepared the manuscript, and subjected it to checks of a most exacting nature, the problem of publication had to be faced.

A. Fletcher, in Art. 6.1 of the "Index of Mathematical Tables", lists fundamental tables of logarithms, and gives ten substantial tables to twelve decimals or more. Of these, three only have been published: Thompson's table to twenty decimals;

Briggs's table (in 1624) to fourteen decimals; and the table of Spenceley, Spenceley and Epperson (in 1952, by the Smithsonian Institution) which gives twenty-three decimals, but has only ten thousand arguments. The difficulties of publication are clear, and the remarkable achievement of Thompson in purchasing a Monotype keyboard and setting up the whole table himself is thereby enhanced. A single-handed effort of this nature deserves publicity: Thompson, virtually single-handed, has computed, checked, set up in type and proof-read the whole of the tabular material of more than nine hundred pages, and the checks and proof-reading have been as thorough as the most exacting of table-makers—that is, Thompson himself—could desire.

The tables are accompanied by interesting and valuable introductory matter on interpolation and on the construction of the tables, and include several auxiliary tables of logarithms and antilogarithms to twenty-one decimals. A translation by J. T. Foxell of "The Life of Henry Briggs", by Thomas Smith (1707), is also included. This is a book to last for centuries and should be in all computing libraries.

J. C. P. MILLER

VIBRATION IN ENGINEERING STRUCTURES

Introduction to a Study of Mechanical Vibration

By G. W. Van Santen. (Philips' Technical Library.) Pp. xvi+296. (Eindhoven: N. V. Philips' Gloeilampenfabrieken; London: Cleaver-Hume Press, Ltd., 1953.) 35*s*.

THE author of this book regards sinusoidal strains as the *bête noire* of the engineer, and in consequence his main concern is with the measurement, origin and elimination of mechanical vibration in engineering structures. The earlier chapters develop in a readable and competent manner the standard theory of the behaviour of simple mechanical systems, both idealized and of engineering importance, vibrating at or near a natural frequency.

Chapter 9, on vibration propagation, raises the question of the degree of over-simplification which is allowable in a volume which professes to be an introduction. The section here on the velocity of transverse waves in a bar achieves excessive over-simplification by assuming that the lateral displacements arise entirely from shear strains. The propagation of shear waves is best illustrated by the torsional case, given later, which lends itself quite simply to an exact analysis. The transverse wave is more complex, but could be introduced with profit in an alternative over-simplified form by assuming that bending strains are predominant. This would lead to a logical introduction of dispersion, which is only vaguely hinted at in the book. A similar question of over-simplification is presented in the rather naïve discussion of fatigue; for example, the statement that fatigue failures "are not accompanied by any distortion of the part" is misleading without further qualification.

The chapters on vibration measurement and its associated pitfalls constitute the most valuable part of the book, in which the author clearly enters his special field. The reader hoping to acquaint himself with a representative selection of measuring instruments may be a little disappointed to find the examples drawn almost exclusively from those marketed by the author's company; but the range turns out to be sufficiently extensive to form the basis for adequate discussion.

The book is well produced at a price which represents fair value for money by present standards, but this edition would be improved by more diligent proof-reading. The translation from the Dutch is good, but in parts the ideas do not flow so sweetly as they might. The volume can be strongly commended to the attention of those concerned with the experimental analysis of vibration in engineering structures. The most serious student who seeks a sound basis from which to attack the more advanced theoretical aspects would do well to peruse den Hartog first, for in the book under review he will miss the fascinating examples which are a sure means of providing a grasp of the fundamental principles.

K. M. ENTWISTLE

Rh BLOOD GROUP

Rh–Hr Blood Types

Applications in Clinical and Legal Medicine and Anthropology. Selected Articles in Immunohematology. By Prof. Alexander S. Wiener. Pp. xii+764. (New York: Grune and Stratton, Inc., 1954.) 11.50 dollars.

An *Rh–Hr* Syllabus

The Types and Their Applications. By Prof. Alexander S. Wiener. (Modern Medical Monographs—No. 9.) Pp. xii+82. (New York: Grune and Stratton, Inc., 1954.) 3.75 dollars.

IT was in 1940 that Landsteiner and Wiener described the *Rh* blood group, and since then research into this particular group has been continuously carried out by workers all over the world. It has become the most complicated human blood group and is now known to be of clinical importance; the studies that have been made have added considerably to our knowledge of human genetics.

Prof. A. S. Wiener has made very many contributions to this work, and the first of these two books, "*Rh–Hr* Blood Types", consists of a selection of the author's papers bound together. Research workers will have read most of Prof. Wiener's papers, but in any event this is a book for the specialist and it may be useful to have a number of selected reprints bound together, since it makes reference to points of detail much easier.

The other work, "An *Rh–Hr* Syllabus", is a little monograph about the *Rh* blood group, its relationship to disease and anthropological and medico-legal applications. I liked this little book and found it pleasant and readable; persons with no special knowledge of blood groups will find it useful and helpful.

One of the difficulties about the *Rh* factor is that there are two separate systems of notation depending upon the theory one holds about this blood group. Prof. Wiener puts forward his theory of multiple allelic genes and his *Rh–Hr* notation and dismisses the Fisher–Race notation used by most British workers. It is a pity, too, that Prof. Wiener has extended the difference in notation by using anti-F and anti-J for what are known to most British workers as anti-Fy^a and anti-Jk^a antibodies. It is to be hoped that the notation difficulties in this field will be resolved satisfactorily in the course of time.

F. STRATTON

THE ROYAL SOCIETY

ANNIVERSARY ADDRESS BY DR E. D. ADRIAN, O.M., P.R.S.*

AWARD OF MEDALS, 1954

Copley Medal: Sir Edmund Whittaker, F.R.S.

WHITTAKER is probably the best-known British mathematician by reason of the numerous, varied and important contributions which he has made and the high offices which he has held. For many years he was the head of the flourishing mathematical school at Edinburgh which owes its whole being to his activity.

His work shows extraordinary versatility. He has written five outstanding books, on entirely different subjects, and some fifty to sixty papers which touch on almost every branch of pure and applied mathematics. Of his books, perhaps the most important is "A History of the Theories of Aether and Electricity", which he has just completely rewritten in a second edition of two volumes. This great work gives a critical appreciation of the development of physical theory up to the year 1925. All his writings show, besides their more technical qualities, powers of arrangement and exposition of a most unusual order; and his treatises of dynamics and analysis have had a considerable influence on mathematical thought both in Great Britain and abroad.

It is only possible to mention a few of Whittaker's original contributions to knowledge (beyond the considerable number absorbed in his books). He has made important additions to the theory of the solution of differential equations, ordinary and partial, by definite integrals; to the theory of Lamé and Mathieu functions, the functions of the elliptic and parabolic cylinders, and the integral equations associated with them; to the theory of interpolation; and to the theory of the solution of dynamical problems by trigonometrical series. He has also, in recent years, made a number of interesting contributions to the pure mathematics of relativity, electromagnetism and quantum theory. The astonishing quantity and quality of his work are probably unparalleled in modern mathematics, and it is most appropriate that the Royal Society should confer on Whittaker its most distinguished award.

Rumford Medal: Dr. C. R. Burch, F.R.S.

Dr. Burch has made outstanding contributions in the development of new techniques for the production of high vacua. Using a molecular still of his own design, he produced a range of oils, greases and waxes having very low vapour pressures. He developed modified diffusion pumps suited to these low vapour-pressure oils which in very many cases have made the use of refrigerants unnecessary and have superseded the mercury diffusion pump. With these pumps and various other devices he pioneered high-vacuum engineering as we know it to-day. Some of its products—continuously evacuated valves, high-voltage tubes, X-ray crystallographic tubes, aluminizing tanks, etc.—he also designed in the early period. These developments have formed an essential part of the design of the high-vacuum devices used in the production of high-speed particles.

Many of the joints in Burch's original pieces of apparatus involved the use of flat surfaces, and he became interested in the science of optics necessary for the study of the production of surfaces to very accurate shapes, and devised a technique for making microscopic phase-retarding disks needed for testing them by phase contrast.

This was one of the techniques used in his next achievement—the perfection of the reflecting microscope. Although the principle of the instrument has long been known, Burch has been responsible for making it practically useful. His theoretical consideration of the problem showed for the first time the conditions under which good results can be expected and the limitations which must be faced.

The introduction of reflecting microscopes may well produce revolutionary changes in many aspects of microscopy, including microbiology. Since the system is wholly achromatic, it remains at the same focus for all wave-lengths. Identification of substances by plotting the absorption curve in the ultra-violet can now be made by the use of a reflecting microscope and a continuous spectrum, and the possibilities of microscopy in the infra-red are greatly extended.

Royal Medal (A): Sir John Cockcroft, K.C.B., C.B.E., F.R.S.

Sir John Cockcroft turned to physics after an early training as an engineer. In conjunction with Dr. E. T. S. Walton he was the first to transmute elements by purely artificial means, setting the crown on Rutherford's work which had proved that bombardment by α-particles from radioactive substances could transmute many of the lighter elements. Cockcroft's work in this field is outstanding both for its scientific consequences and as a discovery in technique. The original experiments of Cockcroft and Walton are the seed from which has grown the whole new science of nuclear chemistry, in which artificially accelerated particles are the reagents which produce varied changes in the nuclei of elements which they bombard. Indeed, a large fraction of the researches now being carried out in the physics laboratories in Great Britain and in the United States arise directly from his work.

Shortly before the Second World War began, Cockcroft had realized the great importance of radar methods of aircraft detection for the defence of Britain, and his influence at the Cavendish Laboratory and later at Malvern was of decisive importance in the development of radar.

In 1944 Cockcroft returned to nuclear physics and was in charge of a large group of British, French and Canadian scientists working on plutonium production, first in Montreal and then at the newly developed

---

* Delivered at the Royal Society on November 30.

Canadian research establishment at Chalk River. When, after the War, the Atomic Energy Research Establishment was set up at Harwell, Cockcroft became its director. Under his guidance it expanded rapidly, and at the same time provided much of the basic information needed for the large-scale production of plutonium in Britain. He has maintained a balance between pure and applied research which has built up in the Establishment a fruitful research atmosphere and has led to important new developments in the use of atomic energy.

Royal Medal (B): Prof. H. A. Krebs, F.R.S.

Prof. H. A. Krebs has made unique contributions to our understanding of the intermediary metabolism of nitrogenous substances and of carbohydrates in living cells, and in his recent work he has helped to bridge the gap which exists between our understanding of the chemical activities of cells and of the way in which these activities help to maintain ionic gradients within the living organism. In the course of these researches he has devised many valuable new methods for the study of cell metabolism.

The main advances for which he has been responsible are numerous and varied. In the realm of nitrogenous metabolism he was able to demonstrate the catalytic function of ornithine in the conversion of ammonia and carbon dioxide to urea by liver tissue. In his work on amino-acid metabolism he showed that kidney and liver tissues contain the system which oxidizes L-amino-acids, while kidney extracts have an active D-amino-acid oxidase; these important enzyme systems attack amino-acids to form ammonia and the corresponding keto-acids.

He discovered the metabolic reaction by which proline can be converted into glutamine, and he has shown the basic significance of glutamine in the inter-related metabolism of amino-acids and carbohydrates, and also in the transport of ions across cell membranes.

His greatest discovery is the tricarboxylic acid cycle, commonly referred to as the Krebs citric acid cycle. This is now accepted as one of the principal means of biological oxidation. Its basic significance in cellular metabolism scarcely needs emphasizing, for it accounts for the complete oxidation to carbon dioxide and water of the two-carbon fragments which arise in the intermediate metabolism of most kinds of foodstuffs.

In his recent work he has helped to clarify the means by which ions and small molecules are transported within the cell.

In 1953 Krebs was awarded the Nobel Prize for Medicine, jointly with Fritz Lipmann, and the award is an indication of the great value of his discoveries to the advance of biochemistry.

Davy Medal: Dr. J. W. Cook, F.R.S.

Cook is distinguished mainly for his contributions to our knowledge of the polycyclic aromatic compounds, the carcinogenic hydrocarbons and the tropolones, including the alkaloid colchicine.

During the period 1920–28 he carried out an extensive series of investigations on derivatives of anthracenes and related complex hydrocarbons, in the course of which a new type of molecular rearrangement was discovered. He then turned to the chemistry of carcinogenic hydrocarbons and synthesized many homologues and derivatives of 1:2-benzanthracene which were found to be carcinogenic; from these and other studies, indications of the nature of the chief carcinogenic agent in coal tar pitch were deduced. Further, Cook was able to enunciate certain broad generalizations regarding the structural conditions necessary for carcinogenic action within this group of compounds. By fractionating 2 tons of coal tar pitch he isolated the pure potent crystalline carcinogen, and with the aid of fluorescent spectroscopy this agent was shown to be 3:4-benzopyrene, identical with a synthetical specimen. Thus Cook was able to demonstrate for the first time the nature of tar and certain mineral oil carcinogenic agents, results which have proved invaluable in studies of certain aspects of the cancer problem.

During the period 1939–54 Cook made outstanding contributions to our knowledge of the alkaloid colchicine and to the chemistry and synthesis of the tropolones. The novel and now accepted structure for colchicine is based almost entirely on Cook's early studies, which stimulated activity in a number of other laboratories.

More recently Cook has extended his studies to the examination of the structure of metabolic products of the carcinogen, 3:4-benzopyrene, and to the oxidation of benzenoid hydrocarbons by novel methods.

In these original studies Cook has tackled a series of extremely difficult and complicated problems with an exceptional knowledge of general organic chemistry coupled with great experimental ability. In the course of his purely chemical studies, Cook has been quick to detect the biological significance of his results, and his findings have provided weapons of attack, if not the keys, to a number of problems in the biological field. Of the results which Cook has achieved, it can be said that they have fundamental importance either to general organic chemistry or to biology or to both.

Darwin Medal: Dr. E. B. Ford, F.R.S.

Dr. E. B. Ford, reader in genetics in the University of Oxford, has made important contributions to all departments of genetics; and, in particular, he has extended and enriched Darwinian thought in two crucial ways: first, the reformulation of Darwinism in terms of the Mendelian theory of inheritance, and second, the extension of Darwinian theory to natural populations.

Ford is the foremost authority on the genetics of Lepidoptera. In studies of a single natural population of moths continued over many years, he was able to show that the genetic diversity of the population varied with its size. Rapid increase of numbers was accompanied by an outburst of variation; in leaner years the individual members of the population were highly uniform. Ford used wing coloration in moths of the genus *Abraxas* to demonstrate the fundamental truth that the 'dominance' of a gene is profoundly influenced by the action of other genes, and therefore by natural selection; with the effect that a factor intermediate in its expression in the heterozygous state could be caused to become dominant or recessive at will. More recent work on Lepidoptera has shown up with particular clarity the sensitivity of the response of even small natural populations to the influence of selection: in altering the genetical structure of such a population, natural selection has proved to be a more potent influence than the vagaries of random mating and random survival. As a corollary, Ford has shown that genetical variants which a superficial and subjective judgment have dismissed as being 'trivial' or of no adaptive significance cannot in reality be so regarded. This work, much of it carried out in collaboration with Sir Ronald Fisher, has clarified and strengthened Darwinian theory in a most important degree.

A complete understanding of Darwinian theory must in the long run turn upon a knowledge of how genetical factors exercise their effects in development. In this field, too, Ford has made important contributions. In collaboration with Dr. J. S. Huxley he showed that one important means by which different genes produce their several effects is by influencing the rate rather than the nature of chemical reactions. More recent work on the genetical basis of wing-coloration in Lepidoptera has been distinguished by the way in which Ford has bent chemical methods to the solution of biological problems.

A single example may be given of Ford's wider influence on genetical thought. At a time when many geneticists were still preoccupied with the analysis of single-character differences and their rules of segregation, Ford was particularly insistent on the need for appreciating the concerted and harmonious action of the assembly of genes considered as a whole, and his concept of the 'gene complex' has had an important effect on the general background of genetical thought.

Dr. Ford's work thus very evidently merits the Society's award for work "of acknowledged distinction in the field in which Charles Darwin laboured".

Hughes Medal: M. Ryle, F.R.S.

Martin Ryle is the leader in the recent developments in radio-astronomy in England. By adapting war-time techniques, he developed a radio analogue of the Michelson stellar interferometer, and he showed how it could be used to detect localized sources of radiation against a continuous background.

With these new and powerful methods he has been able to demonstrate that the solar radiation comes roughly from the area of the visible disk, and that sunspot radiation comes roughly from an area the size of the spot and is often circularly polarized. He showed that there are a large number of radio-stars, and he has detected and roughly located about a thousand of these. He measured the position of a few of them with such accuracy that the optical astronomers have been able to identify them with visible objects. He developed a Fourier analysis method for measuring the distribution of emission across the solar disk and has used it to show that this distribution is unsymmetrical and varies with time. He has used the occultation of a radio-star by the solar corona to investigate the scattering of waves by the corona. He showed that the scintillations of radio-stars were produced by scattering in the ionosphere, and he has used the observations to investigate ionospheric irregularities and their movements.

Ryle has always been very productive of theoretical ideas to account for his observations, and he has pointed out their interesting consequences for cosmological theory.

He has shown that he can pass on his ideas and his enthusiasm to others, and he is the leader of a small and able team which is making major advances in this new field.

THE DIVERSITY OF SCIENTIFIC ADVANCES

When he admits new Fellows to the Royal Society and when he presents the medals at the annual meeting, the President performs his two most pleasant and most important duties. And the range of natural science is now so vast that he need not feel embarrassed by his lack of understanding of the work which he rewards. One hundred, or even fifty, years ago there was far less to understand: we can well believe that there were many Fellows of the Society who knew at least the vocabulary and the general content of every branch of natural science. We still have a few who can survey the whole field—and perhaps we never had more than a few—but certainly it becomes every day more difficult to find scientists whose interests are wide enough to assist the advance by helping the specialists to understand one another.

There is in the Library of Trinity College, Cambridge, a collection of letters illustrating the value of such help. They were written between the years 1830 and 1860 by two Fellows of the Royal Society, Michael Faraday and William Whewell, the great discoverer seeking advice from the most learned scholar of his day. The correspondence reminds us how far we have gone in these hundred years, though it is not surprising that Whewell could assist Faraday, for both of them were exceptional people. Whewell was the Master of Trinity of whom it was said that there was no subject on which he did not speak with authority. His two books on the inductive sciences can still be read with admiration and he had made important contributions to the study of architecture, law and theology. Faraday was in difficulties with his experiments on electrolysis. He needed new terms to describe what he was doing and, having called the two poles 'electrodes', he was uncertain how to differentiate them and how to name the products of current flow. As he was anxious to avoid theoretical implications, he thought of calling the electrodes 'Voltode' and 'Galvanode' or even 'Alphode' and 'Betode'. Whewell makes no reference to this suggestion but, in a letter dated May 5, 1834, he strongly advises the terms 'Anode' and 'Cathode'. The letter continues:

> "If you take *Anode* and *Cathode* I would prefer for the two elements resulting from electrolysis the terms *Anion* and *Cation*, which are neuter participles signifying *that which goes up* and *that which goes down*; and for the two together you might use the term *ions* instead of *Zetodes* or *Stechions*."

And Faraday replies ten days later to say that he has taken Whewell's advice and ends his letter:

> "I am quite delighted with the facility of expression which the new terms give me and I shall ever be your debtor for the kind assistance you have given me."

Whewell's assistance did not end there. In 1836 he suggested the term 'dielectric', and there is a letter written about 1850 which begins:

> "My dear Sir,
> I am always glad to hear of your wanting new words, because the want shows that you are pursuing new thoughts and your new thoughts are worth something."

This time the new word he has to suggest is 'paramagnetic'.

In these days when Faraday was still pursuing new thoughts and Clerk Maxwell was still an undergraduate, it would not have been so difficult to select the most important scientific advance of the year and to point out its significance in the general store of knowledge. But now the store expands so rapidly that it is much more difficult to see where the advance has been greatest. We are farther into the mighty maze and have split up into groups, all of them too deeply engaged to consider the plan. Many of these groups, indeed, are now in territory so far from the entrance that only the grey beards can tell you how they came there—the young pioneers have learnt the dialect of the district and all their interest lies ahead.

We must face the fact that scientists to-day are hard put to it to keep in touch with one another, and that they seldom trouble to signal their position to headquarters. We need not take this too seriously. Parts of the maze may be left unexplored or may be explored twice over, but no permanent harm will come of it. Yet the different groups ought not to be left entirely alone. Though they would resent advice or patronage from those who cannot appreciate their problems, they will go more cheerfully if they are encouraged from time to time by the approval of the scientific world.

It is part of the function of the Royal Society to show this approval. We can still hope to do it effectively by the award of medals, for the achievements which they crown are of a kind which we can all appreciate, though as individuals we may not understand their full content. But the approval of the Royal Society would soon become valueless if we lost either our corporate view of the general enterprise or the close contact of our Fellows with its many special divisions. If we are to retain both, it is more than ever necessary for us to keep our programme and our whole organization under constant review. The position changes rapidly and already great care is needed to see that we are not guided too much by memories of what it was twenty, or even ten, years ago. There are fresh growing-points to demand attention, and we must be ready to accept their claims and if necessary to revise our estimates of the relative importance of established branches. No one likes to think that the special branch which he cultivates is now less fruitful than it was; but we must be careful that our approval is not spread too thin to give much encouragement to the new growths.

An Experiment in Lamarckianism

Having emphasized the need for looking forward rather than backward, I can turn with a clearer conscience to an experiment which has just been concluded and is none the less interesting for having started twenty-two years ago. It is an investigation of the late Prof. W. McDougall's claim to have demonstrated the inheritance of a reaction produced by training, an inheritance which could only be explained on the lines of Lamarck's theory. The report which has just been published is the fourth of a series by a team headed by the late W. E. Agar and more recently by Prof. O. W. Tiegs. I have a special reason for mentioning it, for to physiologists of my generation it will bring back a vivid picture of a meeting in Edinburgh thirty-one years ago. It was at the Eleventh International Congress of Physiology, and we had come to hear a lecture prepared by Pavlov and delivered in English by his son, dealing with recent developments in his work on conditioned reflexes. No one who knew Pavlov will be surprised that our attention was sometimes diverted from the substance of the lecture to the spectacle of its author listening intently to the English version, for Pavlov, like Rutherford, had a vigour of mind and body which could not escape notice. But the lecture ended with an account of some preliminary results on a new problem, that of the inheritance of conditioned reflexes, and these compelled attention because, although they were not yet conclusive, they seemed to show a positive effect. Rats which had formed a conditioned reflex to the sound of a bell bore litters which needed less training to establish the same reflex in them. It looked as though Lamarck might be right after all, that a modification acquired by the individual in consequence of its efforts to adapt itself to its environment might be transmitted in some degree to its descendants.

Pavlov returned to Leningrad, and not long after we learnt that further work had revealed a source of error and that, in fact, he could find no good evidence of the inheritance of reactions set up by training. But William McDougall, a Fellow of our Society and a distinguished psychologist, had been working on similar lines, and his experiments showed a positive effect small enough to need careful assessment but too large to set aside. McDougall gave his rats the choice of escaping from a water tank by swimming towards a light or a dark exit. They could escape in comfort by the dark exit but received a mild electric shock if they chose the light, and before long they never made the mistake of doing so. The amount of training needed to establish the habit was averaged from the performance of large numbers of rats bred from a standard stock, and it was found that with successive generations the training needed became progressively less; and that after the thirty-fifth generation the rats showed a distinct preference for the dark exit from the first time that they were placed in the tank.

McDougall continued his experiments until 1937 (he died in 1938) and replied vigorously to his critics. The most important criticism was that of F. A. E. Crew, who conducted a similar training experiment lasting over eighteen generations and found no evidence of improvement. Agar and Tiegs began their work in 1932. It has been extended over fifty generations and has involved the training of 4,654 rats; its results agree with Crew's in showing no evidence that the training of one generation makes the next need less training to acquire the same certainty of response. Their experiments confirmed McDougall's to the extent that they too obtained long-duration trends of improvement in learning-rate, but they found that they were shown equally by a control series of rats of untrained ancestry and that the effect was not sustained. It seemed to be correlated with general changes in the health and vigour of the laboratory colony, changes which had nothing to do with the training process.

The problems of inheritance cannot be studied without experiments running on from one generation to another, and the results are bound to come slowly if the organism is not one which reproduces itself in a very short time. Certainly an experiment which may last twenty years is not to be undertaken lightly, for in that time so much may happen to threaten its survival. But this one has survived all the hazards of our time, and its authors will not need to be congratulated on having achieved their purpose.

Their purpose was to examine McDougall's case for a Lamarckian type of inheritance, and they have found that the evidence is against it. Most of us would have been rudely surprised if the result had been positive instead of negative; but if their experiment had not been made, we should have had an uneasy feeling that McDougall's conclusion might after all be justified, although Crew's experiments gave it no support.

The same cause for uneasiness may arise whenever a laborious and difficult investigation has given results which seem to contradict prevailing theories but are not decisive enough to be taken without confirmation. We realize that the experiments must be repeated and that it may be a wearisome business demanding great dexterity, constant attention and the building up of elaborate apparatus. There will be little scope for originality except in the devising of further controls, for the new experiments must not differ appreciably from those they are intended to check. Most of us start with a bias in favour of the orthodox view, and as we know that the pitfalls increase with the length and complexity of the experiment, we shall be surprised if the outcome is not the expected negative. When it turns out that way, we shall be grateful to those who have cleared up our uneasiness, but glad that we could think of adequate reasons for spending our time on something else.

No doubt we shall not have spent our time more profitably. The new experiments usually reveal some unsuspected factor which made the original result misleading, and this factor may be an important clue in different problems. But work of this sort rarely meets with the recognition it deserves, and this is a good opportunity for pointing out that our general advance could not go on without it.

The advance of science must depend on the initiative of those in the front line of research. It must be the aim of each special branch to explore the alleys it has opened up, including those which are most probably blind; but as long as the branches are not controlled from headquarters, their members will decide how this is to be done. Control by headquarters is sometimes necessary: we cannot demand that we should always be left to choose our own problems, for there are periods when we must all do as we are told, periods of emergency when we are threatened by war or famine or disease and must all join in a concerted attack. In fact, as scientists we have a double responsibility, for our general aim is to advance our understanding of Nature, but we are now the members of a profession which has special responsibilities because of the way in which it can affect the whole structure of civilized life. The immediate claims of society have to be met, and for this we must be willing to do more or less as we are told. For the long-term objectives we can still do better when we are allowed our independence, but only because there are some of us who will face the laborious work when there is no other way of resolving a doubt.

THE COPLEY MEDAL AND ITS FOUNDER

By Engineer-Captain EDGAR C. SMITH, O.B.E., R.N.(Retd.)

When in 1773 Sir John Pringle, president of the Royal Society, presented the Copley Medal to Priestley for his "Many Curious and Useful Experiments on Different Kinds of Air", he referred to it as "the palm and laurel of this community". An earlier president, Martin Folkes, when handing the Medal to John Harrison, of chronometer fame, had spoken of it as "this small but faithful token of their regard and esteem". Later, Davy called it "the ancient olive crown of the Royal Society", while Cuvier in his *éloge* of Priestley wrote: "La Société Royale lui décerna la médaille de Copley, que l'Angleterre considère comme le prix le plus noble auquel on puisse arriver dans les sciences. L'Académie de Paris lui accorda un prix non moins noble, l'une de ces huits places d'associés étrangers". In the eighteenth century there were few scientific societies and still fewer prizes, but to-day, in spite of the great increase in the number of scientific institutions and awards, some of the latter of which are accompanied by large sums of money, the Copley Medal with its honorarium remains what it was to Pringle, Folkes, Davy and Cuvier, although in the press of public affairs its significance is to-day often overlooked.

While this is true, it is fairly certain that few readers know much of its history or of its founder. Ever since 1736 when the first Copley Medal was struck, it has, with some exceptions, been awarded annually, and the long lists of recipients, especially those of the past and present centuries, include the names of many of the greatest men of science who ever lived, no matter what their nationality. A brief account of the founding of the Medal is given in Weld's work, "A History of the Royal Society with Memoirs of the Presidents compiled from Authentic Documents", published in 1848; but Weld knew little of Copley, and neither did the writer of the notice of him in the "Dictionary of National Biography". Thanks, however, to the researches of Prof. W. H. G. Armytage, of the University of Sheffield, much relating to Copley and his activities has been brought to light, and some of the results are to be found in Prof. Armytage's article entitled "Sir Godfrey Copley, F.R.S., 1653–1709. Some Tercentenary Glimpses through Letters to his Friends", published in *Notes and Records of the Royal Society of London* (11, No. 1; January 1954). From this it is seen that Copley was a public-spirited man of varied interests and a faithful friend and correspondent.

The exact date of Copley's birth is not known, though evidence points to the year 1653; but it appears certain that he died in Red Lion Square, London, on April 9, 1709, and was buried in the parish church of Sprotborough, about three miles from Doncaster, Yorkshire. He thus lived through the reigns of Charles II, James II and William and Mary, and a part of that of Queen Anne. His father, the first Sir Godfrey, had been made a baronet soon after the restoration by Charles II, and when he died about 1684 his son succeeded to his title and estate, including Sprotborough Hall, then one of the stately homes of England, but now no longer standing. Of Copley's education and upbringing little is known, though he was admitted to Lincoln's Inn in 1674. Following in his father's footsteps, he served as member of Parliament, first for the little town of Aldborough and then for Thirsk, and was High

Diameter 2 25 in, bronze (replica)

Sheriff of Yorkshire. He was twice married, first to Catherine, daughter of John Purcell, of Nantriba, Montgomeryshire, by whom he had an only daughter, Catherine, and secondly, to Gertrude, daughter of Sir John Carew, of Antony, Cornwall. His daughter became the wife of Joseph Moyle, whose descendants in 1768 assumed the name of Copley and in whose favour the baronetcy was revived ten years later. The present representative of the family is Robert Godfrey Wolseley Bewicke-Copley, Baron Cromwell.

As a politician, Copley was assiduous in his attendance at Parliament, and outspoken in his views, as can be seen by his speech against the bill of attainder brought in at the time of the conspiracy of Sir John Fenwick and others: "It is the Custom and Law of our Nation", he declared, "to require two positive witnesses to prove Treason. . . . I look upon it as a fundamental Breach of those Rules, for an accusation to be given in against any Man behind his Back, by he knows not whom, or by any with whom he is not confronted, and brought Face to Face. . . . If this method of Proceeding be warranted by an English Parliament, there is an end to the Defence of any Man living, be he ever so innocent". He was much concerned with the urgent problem of the reform of the currency, a matter which led to Newton's appointment to the Mint, and during the early campaigns of Marlborough he was Comptroller of Army Accounts. Had he lived longer, the world would have heard more of him.

Devoted as he was to his public duties, Copley was no less interested in his native county, embellishing his mansion, improving his gardens and corresponding with and visiting other Yorkshire worthies such as Ralph Thoresby and Thomas Kirke. He tried to improve the navigation of the River Don, was interested in pumping plant, water supply and fountains, and at Sprotborough Hall constructed what was probably the first indoor swimming bath. In a letter to Hans Sloane, he described the bath as being about 34 ft. long, 16 ft. wide, 6 ft. deep and lined with lead. It could be filled to a depth of 4½ ft. by his water engine in five hours. "Two or three faggots," he added, "and a sack of Coales doth warm it equall to ye heat of your body. . . . My wife and some Ladys of her acquaintance have gone in it together & are much delighted with it. I am sure this fancy of mine will be followed by some one who perhaps may be willing to outdo me in making one 3 times as large."

Copley's closest friend in London was Hans Sloane, who was seven years his junior and who outlived him forty-four years. Sloane was admitted a Fellow of the Royal Society in 1684, was secretary of the Society during 1693–1713, and in 1727 succeeded Newton as president. Copley was admitted a Fellow in 1691 and six years later was elected a member of Council. He often enjoyed the company of his fellows at one of the coffee houses or at "Pontack's", and his letters contain references to his mathematical books, prints and instruments, to lodestones, air pumps, Napier's Bones, surveying wheels and the voyages of Halley and Middleton. Up to the time of his death, the Royal Society was meeting in the somewhat dilapidated Gresham College, Bishopsgate Street, in the City of London, once the mansion of Sir Thomas Gresham, and it was here the brilliant and versatile Hooke was for long curator and demonstrator. In old age, however, he became penurious and in one letter Copley wrote: "Dr. Hooke is very crazy; much concerned for fear he should outlive his estate. He hath starved one old woman already and I believe he will endanger himself to save sixpence for anything he wants . . ."; and on March 4, 1702–3, he wrote again: "Your old *Philosopher* is gone at last, to try experiments with his ancestors. He is dead, they say, without a will: had only a poor girl with him, who, seeing him ill, went to call somebody; and he was quite gone before they came". In another letter he wrote: "The *poor Corporation* of *London* stand in need to make some profit of the ground of *Gresham College*. I wonder old Dr. Hooke did not choose rather to leave his 12,000 l. to continue what he had promoted and studied all the days of his life (I mean mathematical experiments) than to have it go to those whom he never saw or cared for. It is rare that

Virtuosos die rich, and it is a pity they should if they were like him . . .".

It was in the year following Hooke's death that, on October 14, 1704, Copley made the will in which he bequeathed to Hans Sloane and Abraham Hill (1635–1721), F.R.S., the sum of "one hundred pounds, in Trust for The Royal Society of London for improving natural knowledge, to be laid out in experiments, or otherwise, for the benefit thereof, as they shall direct and appoint". Sloane and Hill accordingly dealt with the bequest until Hill's death, after which Sloane was entirely responsible; and not until he died in 1753 did the Council make the awards. It is thus seen that the early history of the bequest belongs to the time when the Royal Society was meeting in its new quarters in Crane Court, Fleet Street, under the successive presidencies of Newton, Sloane and Folkes.

Though from a letter of Franklin's it appears that the interest on Copley's bequest was being used as early as 1717, the first definite record is a minute of a Council meeting in 1731 which ran: "To Mr. Stephen Gray. For his 'new Electrical Experiments' —as an encouragement to him for the readiness he has always shown in obliging the Society with his discoveries and improvements in this part of Natural Knowledge". A second award was made to Gray in 1732, but in neither case was the amount stated. Gray was a Kentish man who had devoted himself to astronomy and other subjects, but who in 1719 had become a Brother in the ancient Charterhouse, London, the buildings of which are now being restored after being severely damaged during the Second World War. He was then about sixty-six years of age, and it was within the walls of the Charterhouse, and at the home of his friend, the Rev. Granville Wheler (1701–70), F.R.S., Otterden Place, near Faversham, Kent, that he made that long series of experiments with feathers, hair, silk, wool, soap bubbles, resin and threads which mark an epoch in the early history of electricity. Gray died in 1736, when about eighty-three years of age, and it was later in that year that, at the suggestion of Folkes, the Copley Medal was founded. Made of fine gold and weighing one ounce two pennyweights, it was first presented to the Rev. John Theophilus Desaguliers (1683–1744), whose services as curator and demonstrator to the Society were as valuable as those of Hooke. All subsequent medals were made of gold until 1941, when the medal was redesigned by Mrs. M. Gillick and changed to silver gilt. Of the medals presented in the eighteenth century, the Royal Society possesses that given to Priestley, while the British Museum has those given to Gowin Knight in 1747 and to Sir William Hamilton in 1770.

There are features in the early history of the Medal before it had attained an international status that are absent in its later story. Altogether, between 1736 and 1800, fifty-nine awards were made; no awards were made on eleven occasions, but duplicate medals were given in 1783 and 1791, while in 1766 no fewer than three were given. It was awarded twice to Desaguliers and twice to Canton, and one of the recipients in 1783 was the nineteen-year-old Yorkshire boy, John Goodricke (1764–86), who in the previous year had discovered the "Period of the Variation of Light in the Star *Algol*". Among other recipients of the Medal in the eighteenth century were the Rev. Stephen Hales, who lies beneath the tower of Teddington Church, which he restored; Benjamin Robins, the gunnery expert, who died in India; the Greenwich astronomers, Bradley and Maskelyne; Smeaton; Benjamin Franklin; the wealthy Clapham recluse, Henry Cavendish; Peter Woulfe, "the last true believer in alchemy", whose rooms were as full of furnaces and crucibles as the laboratory of Paracelsus; Captain Cook; John Hunter; William Herschel; Rumford; and Volta, who held the chair of physics at Pavia.

With the award of the Medal to Volta in 1794, a new chapter in its history opens, for previously all the recipients had been British citizens, if not of British birth. It was, however, not until 1820, when the Medal was given to the Danish physicist, J. C. Oersted, that the name of another foreigner is found in the list of Medallists. There probably would have been others had it not been for the unfortunate effects of the French Revolution and the Napoleonic Wars. Not long before the signing of the Treaty of Amiens in 1802, the Paris Academy of Sciences elected Banks, Maskelyne, Cavendish, Herschel, Priestley and Rumford foreign members, but there was no reciprocal action by the Royal Society. The nineteenth century fortunately saw much of the national animosity die away, and in 1825 Arago became the first Frenchman to receive the Medal, in 1836 Berzelius the first Swedish man of science, and in 1838 Gauss the first German. By then the Rumford and Royal Medals had been founded, and some awarded to foreigners, the Royal Society recognizing with impartiality the debt to Continental investigators and teachers, to whose laboratories and lecture rooms British students began to flock in increasing numbers.

By the middle of the nineteenth century the Copley Medal had become recognized all the world over as the "palm and laurel" of science, and under the successive presidencies of Sabine, Airy, Hooker, Huxley, Spottiswoode, Stokes and Kelvin, the Society again and again acknowledged the work of other nations. It is thus found that, of the fifty awards made during 1851–1900, no fewer than thirty-two were made to foreigners, the list for the decade 1870–79, for example, including Mayer, Wöhler, Helmholtz, Pasteur, Hofmann, Claude Bernard, J. D. Dana, Boussingault and Clausius. Among the British names found in that half-century are Owen, Darwin, Lyell, Joule, Stokes, Kelvin (then Sir William Thomson) and Lord Rayleigh. To this period also belongs the generous gift in 1881 by the then Sir Joseph Copley of a sum in Consols sufficient to provide an honorarium of £50 for each medallist. The value of this investment diminishing gradually, the Council of the Society last year made provision for increasing it to £100.

The present century opened with nothing to disturb the relations of men of science of either Europe or America, and under the presidency of Sir William Huggins, himself a Copley medallist, the Medal was awarded in turn to Willard Gibbs of America, Lord Lister, the Austrian geologist Suess, Sir William Crookes and the Russian chemist Mendeléeff. Next in the list come the names of Metchnikoff, Michelson, A. R. Wallace, G. W. Hill, Galton, Sir George Darwin, Prof. Klein of Göttingen, Ray Lankester and Sir J. J. Thomson, to whom it was given in 1914. With the outbreak of war and the upheavals of the past forty years, the Royal Society was faced with difficulties similar to those of the days of Napoleon, and once again British names appear with greater frequency, as can be seen from the following table:

Copley Medallists, 1915–54

1915	I. P. Pavlov
1916	Sir James Dewar
1917	Émile Roux
1918	H. A. Lorentz
1919	W. M. Bayliss
1920	H. T. Brown
1921	Sir Joseph Larmor
1922	Lord Rutherford
1923	Sir Horace Lamb
1924	Sir Edward Sharpey-Schafer
1925	A. Einstein
1926	Sir Frederick Gowland Hopkins
1927	Sir Charles Sherrington
1928	Sir Charles Parsons
1929	Prof. Max Planck
1930	Sir William Bragg
1931	Sir Arthur Schuster
1932	Dr. G. E. Hale
1933	Prof. T. Smith
1934	Prof. J. S. Haldane
1935	Prof. C. T. R. Wilson
1936	Sir Arthur Evans
1937	Sir Henry Dale
1938	Prof. Niels Bohr
1939	Prof. T. H. Morgan
1940	Prof. P. Langevin
1941	Sir Thomas Lewis
1942	Sir Robert Robinson
1943	Sir Joseph Bancroft
1944	Sir Geoffrey Taylor
1945	Dr. O. T. Avery
1946	Dr. E. D. Adrian
1947	Prof. G. H. Hardy
1948	Prof. A. V. Hill
1949	Prof. G. O. de Hevesy
1950	Sir James Chadwick
1951	Prof. D. Keilin
1952	Prof. P. A. M. Dirac
1953	Prof. A. J. Kluyver
1954	Sir Edmund Whittaker

Whatever the conclusions of a reader may be, it is, however, well to remember the lines,

> "This world is not for aye ; nor 'tis not strange
> That even our love should with our fortunes change . . ."

and in spite of contending political systems and of national prejudices, no man of science will dispute the remark of Davy's that "Science like Nature, to which it belongs is neither limited by time or space. It belongs to the world and is of no country and no age".

OBITUARIES

Prof. A. F. Blakeslee

Prof. Albert Francis Blakeslee, of Smith College, Northampton, Massachusetts, died on November 16 at the age of eighty. Blakeslee will perhaps be remembered as a man who made more varied discoveries than any biologist of his time. Fifty years ago he observed that sexual reproduction in fungi was restricted by a genetic incompatibility, a principle which is now known to limit and direct sexual reproduction in plants and in the lower organisms generally. Thirty years ago in a large series of collaborative studies on *Datura* he began to show a whole unexpected range of chromosome changes (polyploidy, interchange, etc.) underlying the variation of the species. He pursued this work with unremitting zeal throughout his life. But concurrently he was showing how polyploidy could be induced in innumerable plants with the help of colchicine and he was investigating the genetics of the faculties of taste and smell in man as well as of fragrance in the plant itself. At the age of seventy-six, still a guest professor at Smith College, he attended the Stockholm Botanical Congress and gave papers on the chromosomes of species hybrids in *Datura*, on the use of chimæras in elucidating the germ layers of plants, on the culture of excised embryos as a means of growing inviable hybrids, and on the development of *Rudbeckia hirta* by selection from a wild species to a garden plant.

These were only the more successful inquiries that Blakeslee undertook. His energy and curiosity took him into many less productive fields. Two things strike one about his work. One is that he never made any serious mistake of observation. The other is that he never ventured far into interpretation or prediction after his early studies in fungi. Here his interpretation was unfortunate in that he tied the word sex to the property of incompatibility and thereby led his successors astray right down to the present day. In a sense the style of his work is best represented by his diagrams of *Datura* chromosomes as packets. These diagrams were useful in a popular sense so long as one did not take them too seriously. Unfortunately, it seems that Blakeslee did take them seriously. To him they were the real and final thing.

By his alertness and ingenuity and his practical sense in organizing the Station for Experimental Evolution at Cold Spring Harbor (where he worked for thirty years, until his retirement in 1942), Blakeslee kept the botanical world of his day in a state of constant stimulation. C. D. Darlington

Dr. Neville Jones, O.B.E.

Neville Jones, whose death on October 24 has been reported from Bulawayo, was a pioneer in Rhodesian prehistory, and during the years 1913–47 worked out the complete succession of Stone Age cultures in the western part of Southern Rhodesia.

Born in London in 1880, he was educated at Dulwich College and, after working in various capacities, including an appointment as geologist to an expedition to Madagascar in 1906–7, he went to Southern Rhodesia as a missionary in 1912. On retiring from mission work at the age of fifty-five, he at once commenced a new profession and became the first keeper of prehistory at the National Museum of Southern Rhodesia in Bulawayo. Here he was able to devote his whole time to prehistory, and his best scientific work was done during the twelve years in which he held his Museum post.

Important as was his work on the Stone Age, it was by no means his only interest. As a missionary among the Matabele, he saw much of these people and published anthropological notes as well as a valuable historical study, "My Friend Kumalo" (1945). With one very important exception, his field-studies related to the Stone Age; but the exception, the excavation of Mapungubwe in the Northern Transvaal in 1934, shows that Stone Age studies were not all-absorbing for him. His work at this site is incorporated in Prof. Fouche's "Mapungubwe" (1937). Besides his archæological work, he was a botanist and entomologist of no mean calibre, being especially interested in the collection and culture of South African xerophytic plants.

Jones was the moving spirit in the foundation of the Commission for the Preservation of Natural and Historical Monuments and Relics in Southern Rhodesia and was successively its secretary and its chairman.

His lack of formal academic qualifications never greatly worried him, for his wide correspondence enabled him to keep in touch with current thought in his subject; nevertheless, the honorary doctorate conferred upon him by the University of the Witwatersrand during the last year of his life was the most highly prized of his honours.

Jones's work for prehistory will provide a basis which other workers, who knew him not, will accept or, perchance, reject; to his colleagues throughout Southern Africa he has, however, left a personal legacy in his example of quiet, careful and unselfish work for which they are all the richer.

R. Summers

NEWS and VIEWS

Chief of the Royal Naval Scientific Service: Dr. H. F. Willis

DR. H. F. WILLIS, superintendent of the Admiralty Research Laboratory, Teddington, has been appointed chief of the Royal Naval Scientific Service, in succession to Mr. W. R. J. Cook (*see Nature*, 166, 135; 1950), who has become deputy director of the Atomic Weapons Research Establishment, Aldermaston. Dr. Willis, who is forty-five, is a graduate of University College, Cardiff, where he obtained first-class honours in mathematics in 1930 and physics in 1931. In the following year he gained the M.Sc. degree for research on relativity, and he became a Fellow of the University of Wales in 1933. He spent the next two years at Trinity College, Cambridge, engaged on experimental research into the optical properties of molecules, and for this work was awarded the Ph.D. degree. In 1935 he joined the British Cotton Industry Research Association and carried out fundamental research on the diffusion of dye-stuffs into cellulose fibres. These early researches were described in papers published in the *Philosophical Magazine* and in the *Proceedings* of the Royal Society and of the Faraday Society. Dr. Willis entered Admiralty service in 1938, and until 1945 was engaged on underwater acoustics research in the anti-submarine experimental group, where he served with notable success. He was then transferred to the Admiralty Research Laboratory, and until 1953 was leader of the group concerned with problems in electromagnetics and underwater ballistics. He was promoted to the rank of deputy chief scientific officer in January 1950, and became superintendent of the Admiralty Research Laboratory in 1953. The versatility and originality displayed by Dr. Willis in his own researches, and the skill which he has since shown in organizing and directing the work of a large establishment, augurs well for the Royal Naval Scientific Service in the increasingly important part which it is being called upon to play in naval affairs.

The French Canadian Association for the Advancement of Science: Dr. L. Marion, M.B.E.

DR. LÉO MARION, director of the Division of Pure Chemistry of the National Research Council of Canada, has been elected president for 1954–55 of the French Canadian Association for the Advancement of Science. He has also been awarded an honorary D.Sc. by Laval University, Quebec. Dr. Marion, who is fifty-five, is a graduate of Queen's University, Kingston, and a Ph.D. of McGill University, Montreal. Joining the National Research Council in 1929, he became head of the Organic Chemistry Section in 1943, and four years later he took on the added responsibilities of editor-in-chief of the *Canadian Journal of Research*, a post which he still holds. In 1952 he became director of the Division of Pure Chemistry. Dr. Marion's research work has been concentrated on the alkaloids, and for his contributions in this field he was awarded in 1948 the gold Médaille Léo Pariseau of the French Canadian Association for the Advancement of Science. He was elected to the Royal Society of Canada in 1942 and was made an M.B.E. in 1946.

British Participation in an International Atomic Energy Agency

IN reply to a question in the House of Commons on November 16, Sir Winston Churchill stated that during the past seven years the United Kingdom had exported to forty-six countries more than sixteen thousand consignments of isotopes and, at the present rate of seven thousand consignments a year, is the world's largest exporter of isotopes. Both Canada and the United States are also important exporters. The Isotopes Advisory Service offers advice and assistance, and foreign students are accepted at the Isotopes Training School at Harwell. Sir Winston agreed that the United States has given a fine lead towards establishing an international atomic energy agency and that it will have a great effect on the international situation if the Soviet Union can see its way to co-operate fully along these lines. On the same day, the Minister of State, Mr. A. Nutting, told the United Nations Political Committee in New York that, following the allocation by the United States the previous day of 100 kgm. of fissionable material, the British Government is prepared to hold available as required 20 kgm. of fissionable material for use in atomic research reactors abroad. Mr. Nutting added that the British Government has not changed its views as to the objectives of the agency: these are to encourage world-wide research and development of peaceful uses of atomic energy; to arrange for nuclear materials to meet the needs of research, development and practical applications to medicine and other peaceful activities, including the eventual production of power; to foster the interchange of unclassified information; and to prepare for a time when the use of atomic energy for peace becomes the predominant and perhaps the exclusive use of atomic energy.

Sucrose Synthesis in Tobacco Leaves

THE synthesis of radioactive sucrose by tobacco leaves from glucose and glucose-1-phosphate uniformly labelled with carbon-14 has been described by P. V. Vittorio, G. Krotkov and G. B. Reed (*Canadian J. Bot.*, 32, No. 3, 369; 1954). The petioles of detached tobacco leaves were placed for six hours in solutions of labelled glucose and glucose-1-phosphate, and at the end of this time the leaves were extracted with boiling 80 per cent ethanol and the activities of their various carbohydrate fractions determined. The specific activities of both the glucose and fructose moieties of sucrose were found to be high and very close to one another, while that of the free fructose was low. From this the authors have concluded that the fructose component of sucrose is derived from the glucose introduced and not from the free fructose present in leaves. Low activity in starch observed in photosynthesizing leaves indicates preferential transformation of the glucose introduced into sucrose and not into starch. Moreover, respiration of labelled glucose ought to produce labelled carbon dioxide and, after a period of photosynthesis, labelled starch. The isolated starch contained only a small amount of activity, indicating that, in light, sugars were not utilized in respiration to any great extent. In darkness, however, sugars were so utilized, the carbon dioxide evolved being very radioactive. The authors conclude that the mechanism of sucrose synthesis in tobacco leaves must be different from that reported for *Pseudomonas saccharophila*.

Proceedings of the Botanical Society of the British Isles

IT has been decided to replace the "Yearbook" of the Botanical Society of the British Isles by a new publication—the *Proceedings*, which is to appear twice a year, edited by D. H. Kent (1, Part 1; pp. 117). The first number contains such familiar features as plant notes, plant records and abstracts from literature. Each number will also contain papers of general interest on the British flora and, at times, reports of officers, excursions and exhibition meetings, as well as book reviews and obituaries. The present part includes papers on recent work on the Manx flora and the flora of Caldey Island, Pembrokeshire.

Abstracts of Theses for Cambridge Research Degrees

ABSTRACTS of the theses which were approved for the degrees of Ph.D., M.Sc. and M.Litt. in the University of Cambridge during the academic year 1951–52 have been published by the Cambridge University Press (pp. xvii+243; 1954). These abstracts, which vary in length from about 120 to 500 words each, are arranged in the alphabetical order of the faculties under the degree committees of which the research students worked and, within these main divisions, by departments. Sixteen faculties are represented, and two hundred dissertations are reported. These include twenty-six in the Faculty of Mathematics, and in the Faculty of Physics and Chemistry twenty on subjects in organic and inorganic chemistry, ten in physical chemistry and thirty-one in physics. The Faculties of Classics and Divinity are represented by only one each. An index of authors' names is given at the end of the volume, and it is stated that a copy of each dissertation is deposited in the University Library and may only be consulted there. It is to be expected that the substance of the more important dissertations will be published in due course in the appropriate journals; but as it is essential that details of work done, particularly in science, should be made available as soon as possible to those interested, it is a pity that this handy reference volume to research work performed at the University of Cambridge during 1951–52 was not published more promptly, and further that the copies of the dissertations are not available for loan except perhaps from the individual authors.

American Association for the Advancement of Science: Meeting in Berkeley

THE one hundred and twenty-first meeting of the American Association for the Advancement of Science will be held in the University of California, Berkeley, during December 26–31. In addition to the programmes of the Association and its eighteen sections, fifty-nine societies and other scientific organizations have arranged more than three hundred sessions, and another thirty societies are co-sponsoring appropriate symposia. Besides the address of the retiring president of the Association, Dr. E. U. Condon, to be given on December 28, the Association will hold three general symposia as follows: natural resources—power, metals, food; population problems; and the impact of science on society. As in previous years, the main work of the meeting will be divided between the various Sections of the Association, which are as follows: (*A*) mathematics; (*B*) physics; (*C*) chemistry; (*D*) astronomy; (*E*) geology and geography; (*F*) zoological sciences; (*FG*) biological sciences; (*G*) botanical sciences; (*H*) anthropology; (*I*) psychology; (*K*) social and economic sciences; (*L*) history and philosophy of science; (*M*) engineering; (*N*) medical sciences; (*O*) agriculture; (*P*) industrial sciences; (*Q*) education; (*X*) science in general. Among the other meetings to be held in Berkeley at the same time are: the third Berkeley symposium on mathematical statistics and probability; a four-day international conference on animal venoms; a meeting of the International Union for the Study of Social Insects; the annual Academy conference, made up of delegates of the forty-two academies of science affiliated with the Association; and the recurrent conference on scientific editorial problems and the conference on scientific man-power. Further information can be obtained from Sidney S. Negus, Medical College of Virginia, Richmond, Virginia.

Geographical Association: Annual Conference

THE annual conference of the Geographical Association will be held in the London School of Economics, Houghton Street, Aldwych, London, W.C.2, during January 4–7, 1955. The presidential address, by Prof. S. W. Wooldridge, professor of geography, King's College, London, will be on "The Status of Geography and the Role of Fieldwork". In addition to the usual lectures, excursions, etc., there will be a symposium sponsored by the Public and Preparatory Schools Section of the Association, on problems of geography teaching and their relation to preparation for the university. Further information can be obtained from the honorary conference organizer, Prof. W. G. V. Balchin, University College, Swansea.

The spring conference of the Association will be held in York during April 12–16, 1955, and the programme and reservation leaflet for this meeting will be enclosed in the January issue of the Association's journal *Geography*.

Israeli Scientific Papers during 1948–53: Exhibition in London

AN exhibition of scientific papers published by Israeli research workers during 1948–53, covering both pure and applied science, will be held at the Israeli Consulate, 18 Manchester Square, London, W.1, starting on December 7, and will remain open to the public for a fortnight, Saturdays excluded. Sir Francis Simon will open the exhibition and will give an impression of science in Israel during his recent visit to that country. Sir Ben Lockspeiser will also speak, and Sir Robert Robinson will be in the chair. A catalogue will be issued of all the publications concerned, with full names and references, as well as an author index. Further information can be obtained from the Office of the Scientific Attaché of the Embassy of Israel, 2 Palace Green, London, W.8.

University of Glasgow

THE following appointments have recently been made in the University of Glasgow: to the chair of agriculture, Prof. Donald S. Hendrie, principal of the West of Scotland Agricultural College; to lectureships, A. C. MacLean (geology), Dr. E. Gelles (chemistry) and Dr. H. W. Wilson (experimental physics); to Imperial Chemical Industries, Ltd., fellowships, Dr. S. C. Abrahams (senior fellowship) and Dr. H. M. M. Shearer. For the present session, 287 new students (228 men and 59 women) have been admitted to the Science Faculty of the University, compared with 259 in 1953. In the University as a whole, the total number of matriculated students stands almost unchanged at 5,585. The new wing of the Chemistry

Institute (see *Nature*, 173, 119; 1954) is now occupied, and thus once more, after an interval of fourteen years, the whole work of the Department of Chemistry is housed in a single building, which—with a floor space of about 170,000 sq. ft.—is probably the largest chemistry building in Britain; including staff and students, the total population of the Department is well over a thousand.

University of Leeds

The following gifts have recently been received by the University of Leeds: a grant not exceeding £10,000 from the Wellcome Trust to the Department of Pharmacology for the reconstruction and re-equipping of laboratories; £20,000 from Imperial Chemical Industries, Ltd., to the Department of Textile Industries towards the cost of equipping the new man-made fibres building.

Dr. H. E. Nursten has been appointed a lecturer in the Department of Leather Industries of the University.

Christmas Lectures for Young Persons

A number of organizations are holding lectures for young persons during the Christmas school holidays. Among them, the Royal Institution's "course of six lectures adapted to a juvenile auditory" is perhaps the most famous, certainly the most long-standing, and this year the one hundred and twenty-fifth such course will be by Sir Frank Whittle on "The Story of Petroleum"—its uses; geology; exploration, production and transportation; engines and their fuel; refining; and the gas turbine. The lectures will be given at 3 p.m. on Tuesdays, Thursdays and Saturdays during December 28–January 8 at the Royal Institution, 21 Albemarle Street, London, W.1, the fee being, juveniles (10–17 years) £1, adults (non-members) £2. For the first time the Plastics Institute is holding this year a Christmas lecture for young persons, which will be given at 2.30 p.m. on December 30 in the auditorium of the Wellcome Research Institution, 183–193 Euston Road, London, N.W.1, by Dr. J. C. Swallow, chairman of the Plastics Division, Imperial Chemical Industries, Ltd., whose talk, on "The Wonder of Plastics", will be illustrated by a film and supported by practical demonstrations; applications for tickets should be made to the Secretary to the Council, Plastics Institute, Adam Street, London, W.C.2. A Christmas lecture, for persons between twelve and eighteen years old, which the Manchester Federation of Scientific Societies organizes will be given this year by Dr. H. A. Thomas, of Courtaulds, Ltd., his subject being "How Science helps to Clothe us"; the lecture will be given in the Chemistry Lecture Theatre of the University of Manchester at 3 p.m. on January 5 and will be repeated the next day. Applications for tickets should be made through one of the Federation's participating societies.

Announcements

We regret to announce the death of Prof. E. Fermi, For.Mem.R.S., of the Institute for Nuclear Studies, University of Chicago, on November 28, aged fifty-three.

The title of emeritus professor in The Queen's University of Belfast has been conferred on Prof. James Small, professor of botany during 1920–54, and on Prof. J. K. Charlesworth, professor of geology during 1921–54.

The title of professor of biochemistry in the University of London has been conferred on Dr. Henry McIlwain in respect of the post held by him at the Institute of Psychiatry. The title of reader in physiology in the University of London has been conferred on Dr. M. Grace Eggleton in respect of the post held by her at University College.

Prof. John Walton, regius professor of botany in the University of Glasgow, has been elected a corresponding member of the Botanical Society of America.

Prof. F. E. King, Sir Jesse Boot professor of chemistry in the University of Nottingham, has been elected to the board of British Celanese, Ltd. Prof. King will assume a full-time appointment with the company as director in charge of research in September next.

The new Cavendish professor of experimental physics in the University of Cambridge, Prof. N. F. Mott, has invited Prof. H. Bethe, of Cornell University, to spend the academic year 1955–56 in the Cavendish Laboratory as an adviser on the development of nuclear physics in the Laboratory. Prof. Bethe's acceptance of the invitation should prove exceedingly valuable for the future of nuclear physics at Cambridge, since he is particularly well informed about American developments in this field.

Dr. George Porter, until recently assistant director of research in the Physical Chemistry Department, University of Cambridge, has joined the British Rayon Research Association as assistant director and is in charge of fundamental research there. Dr. Porter's research work has been concerned with reaction kinetics and, by means of flash photolysis, with the investigation of the very short-lived intermediates which are to a large extent responsible for chemical change. At the Association he will be continuing his recent work on the absorption of light by aromatic molecules and dyestuffs.

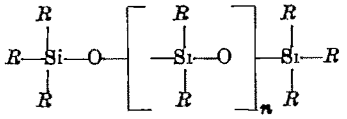
The Massachusetts Institute of Technology is offering a small number of scholarships to university graduates in science, technology and architecture to enable them to work at the Institute during the summer session, June 6–September 24, 1955. Candidates must be British citizens, less than thirty-two years of age, with at least two years experience in postgraduate research, either academic or industrial. Application forms (to be returned by January 3) can be obtained from the Cultural Affairs Officer of the United States Embassy, Room 302, 41 Grosvenor Square, London, W.1.

Under the provisions of the Fulbright Programme, travel grants are available to citizens of the United Kingdom and British Colonies to go to the United States for an academic or educational purpose, provided that they have the financial support in dollars for the visit and have been accepted by an American institution of higher learning. The grants cover the cost of direct travel between a candidate's home and America and return, and are available during June 1, 1955–February 1, 1956. Applications must be submitted by March 15, 1955 (for those travelling between June 1 and July 31), or June 1 (for those travelling after August 1). Application forms and further information can be obtained from the United States Educational Commission in the United Kingdom, 55 Upper Brook Street, London, W.1.

PRODUCTION OF SILICONES

NEW PLANT AT BARRY, GLAMORGAN

PROF. F. S. KIPPING, working in the University of Nottingham at the end of the nineteenth century and early years of the twentieth, carried out many experiments in the field of silicon chemistry. In the course of that research he often obtained polymeric silicon products, which he recognized as containing silicon–oxygen linkages. Such compounds are known as 'silicones', a term which refers to any organo-silicon compound based on a silicon–oxygen structure with hydrocarbon radicals attached to the silicon atoms ; for example :

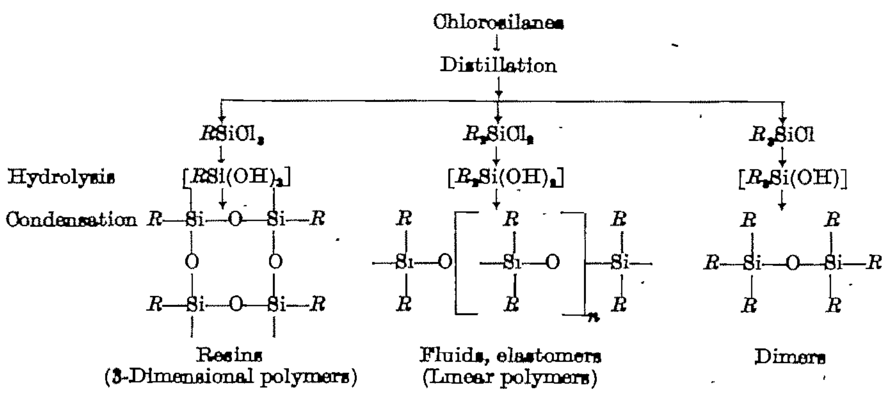


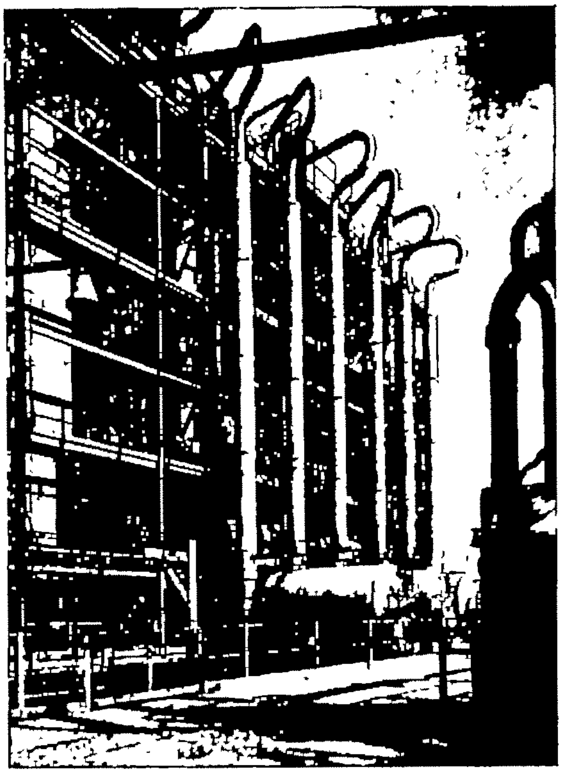
$$R-\overset{R}{\underset{R}{Si}}-O-\left[-\overset{R}{\underset{R}{Si}}-O-\right]_n-\overset{R}{\underset{R}{Si}}-R$$

The group inside the brackets is called 'siloxane'. In the case of the polydimethylsiloxanes (that is, where R is a methyl group), n may vary from zero to several thousands.

The production of silicones in Great Britain is taking place at the Albright and Wilson, Ltd., Silicone Plant at Barry, Glamorgan. Here, on a large scale, with the rigorous exclusion of air and moisture, silicon is treated with methyl chloride at 275–375° C., using copper as a catalyst. The various chlorosilanes, RSiCl$_3$, R_2SiCl$_2$, R_3SiCl, which are so produced, for example, Si + 2RCl → R_2SiCl$_2$, are fractionated into the pure components. This fractionation is difficult because the boiling points of the chlorosilanes are very close together, and fractioning equipment of great efficiency has to be used. The fractionating section is a vital part of the whole plant, and involves fractionating columns of great height and many stages, all controlled automatically. This fractionation gives the mono-, di- and tri-substituted chlorosilanes as pure components. Some of these chlorosilanes are further treated by a Grignard reaction, in order to prepare those types of chlorosilanes which are most needed.

Having obtained pure chlorosilanes, the next step is their hydrolysis by water. The products of hydrolysis condense, and by varying the initial proportions of the different chlorosilanes, a great variety of silicone products can be made ; for example :





Distillation unit showing still pots and batch columns

It can thus be seen that the characteristics of the products are dependent upon the type of chlorosilane or mixture of chlorosilanes used.

The process employed is very complicated, and requires to be carried through many stages with great care in order to produce pure materials in good yield. Since the chlorosilanes are corrosive and toxic, react spontaneously with water, and are highly inflammable, elaborate safety precautions are necessary, and the volatile solvents and intermediate products of the process are stored in buried tanks. The tanks—and indeed all parts of the system—are purged with inert gas to prevent the ingress of air or moisture and to reduce the risk of fire. Incoming solvents are transferred to the storage tanks from the tank cars, in which they are transported, by pumps. On the other hand, methyl chloride, which is also transported by road tanker, is transferred to storage tanks by utilizing its own vapour pressure. All people working in hazardous areas wear protective clothing, including glasses and helmets.

The silicone products so obtained are characterized by good resistance both to water and to extremes of temperature. These are extremely useful properties, and result in silicones being used for such varied purposes as paints for metal surfaces at high temperatures, water-repellent treatment for masonry, concrete, etc., heat-resistant electrical insulation, silicone finishes to fabrics to achieve water repellency and stain resistance, etc. The quality of the products is tested in a technical service laboratory, and the development of new products is also carried out there.

The knowledge and experience of the Dow Corning Corporation in the field of silicone science and technology has been freely available and has been drawn on liberally in the setting up of this plant at Barry.

BIOLOGICAL EVALUATION OF WATER AND EFFLUENTS

On November 3 the Biological Methods Group of the Society for Analytical Chemistry held a symposium in London on "The Biological Evaluation of Water and Effluents". The large attendance and the spirited discussion of the papers gave a good indication of the large number of chemists and biologists now interested—either as consultants or as servants of public authorities or industrial firms—in the assessment and control of pollution.

Dr. B. A. Southgate (Water Pollution Research Laboratory, Stevenage), in introducing the subject, said that, in trying to evaluate the purity either of a surface water or a polluting discharge, chemical and biological methods are usually used in conjunction. Waters to be used as a source of domestic—or sometimes industrial—supply are usually examined bacteriologically; with some surface waters the algal flora is examined frequently, and measures are taken to prevent its interfering with filtration and other methods of treatment of the water. There is a great lack of quantitative information on the distribution of different species of fish in rivers, particularly in rivers polluted by sewage and industrial effluents. Recent work has shown that large numbers of coarse fish enter a channel carrying an undiluted sewage effluent, in which conditions only rarely become lethal; when lethal conditions do occur, it is due principally to depletion of oxygen in solution.

In regulating the discharge of effluents containing oxidizable matter to a stream, a method is urgently required whereby the effect of a given discharge on the oxygen tension in the stream can be predicted. Usually effluents are examined by the test for biochemical oxygen demand or, better, by measuring uptake of oxygen in a respirometer (of which a new modification of an instrument of the Warburg type was described), but it is by no means certain that the rate of oxidation—particularly of ammonia—measured in this way is the same as that which occurs in a stream. In the direct measurement of rate of oxidation in a river, it is necessary to be able to determine the rate of solution of oxygen from the air—known to vary widely with turbulence, surface agitation, and other factors. Dr. Southgate described an attempt to do this by following changes in the oxygen content of air trapped in a light plastic container, open at the bottom, and floating on the surface of the water. Rapid fluctuations may occur in the oxygen tension in polluted streams, and methods of recording the level of oxygenation, continuously or at short intervals, are required. A recently developed apparatus was described in which samples are taken at intervals of ten minutes, the oxygen content being determined automatically, essentially by the method of Winkler; the values obtained are recorded on a chart.

The determination of the toxicity of effluents to fish was then dealt with by Mr. D. W. M. Herbert (Water Pollution Research Laboratory, Stevenage); the object of this work, he said, is to predict, from tests in the laboratory, what effect a given effluent would have on fish when discharged to a river. Laboratory tests under controlled conditions can usually be made only during a period of a few days, though some have been continued for as long as three months; from tests of this kind, one has to try to predict what the effect of a small concentration of a poison, present continuously in a river, would be on a fishery. It is very probable that the toxicity of a river water, containing a fixed concentration of a poison, would in any event fluctuate widely, since the toxicity of most direct poisons which have been examined increases markedly as the oxygen tension of the water containing them is reduced below the air-saturation value. Fluctuations in temperature and *p*H value may also be important; the toxicity of solutions of ammonia, for example, increases rapidly as the *p*H rises and ionization is suppressed.

Dr. J. E. Forrest (Queen Mary College, London) described the effects of polluting discharges on the flora and invertebrate fauna of streams, dividing effluents for this purpose into those containing direct poisons; those, such as sewage effluents, not directly poisonous but containing organic matter; and those which affect a river mainly by raising its temperature. Below a source of serious organic pollution there is a well-marked sequence of changes in the invertebrate fauna and, it was suggested, a study of the fauna in a river might give more reliable information about the state of pollution of the water than would be given by random chemical tests. The relative importance of the level of oxygenation of the water and of the nature of the bottom in influencing the distribution of invertebrates is not yet clear. Normally, of course, if mud and sludge are to be deposited in a river, this will happen in slow-flowing and relatively deep reaches where the oxygen tension of the water is likely to be low, as a result of uptake of oxygen at the mud–water interface, and of the relatively small rate of re-aeration of the water from the air under stagnant conditions. The importance of *Cladophora* (blanket weed) in modifying the character of a stream was stressed; this alga may grow very vigorously in rivers polluted by nitrogenous organic matter.

In a paper on the determination of the safety of water, Dr. E. Windle Taylor (Metropolitan Water Board, London) described the development which has taken place, from about 1880 onwards, of bacteriological methods of examination. Recently, for research purposes, the probable error of bacterial counts, using liquid media, has been considerably reduced by using only two-fold dilutions and examining seven series, each of ten tubes, in each determination; the modern view, however, is that in routine estimations to safeguard the purity of a domestic water supply it is better to increase the number of samples examined rather than to increase the number of tests carried out on each sample. He emphasized that a public water undertaking aims at distributing a safe, but not necessarily a sterile, water; sterilization may be necessary if the water is used in a hospital, and for process water in food industries further treatment may be desirable to improve the keeping qualities of the product. Among the most promising recent developments in methods of examining water are membrane filtration, and the use of synthetic media containing only pure inorganic substances. Dr. Windle Taylor urged—and this was strongly supported in discussion of his paper—that standard bacteriological methods should be used in examining water supplies. Several members also referred to the urgent need for a second edition of "Methods of Chemical Analysis as applied to Sewage and Sewage Effluents", the first edition of which was published by the Ministry of Health as long ago as 1929.

The discussion—a very brisk one—which followed the papers covered a wide range. Opinion seemed to be general that there is a need for a standard method of determining the toxicity of industrial effluents to fish; an attempt is in fact now being made to develop such a method, and the Ministry of Agriculture and Fisheries has announced that it proposes to set up a laboratory in London in which samples submitted will be tested. Several speakers referred to the inadequacy of the widely used test for biochemical oxygen demand of effluents, and it is clear that much further work is required to determine rates of oxidation of pollutants, both under laboratory conditions and in different types of rivers. Only when this information is available will it be possible to predict with confidence the effect of an effluent on the level of oxygenation of a river—a very important matter to a river board proposing to frame by-laws regulating the quality of effluents in its district.

RESEARCH ADMINISTRATION CONFERENCE

THE eighth annual conference on "The Administration of Research" brought together nearly three hundred leaders of industrial, university and government research laboratories at New York University during September 8–10, coinciding with the opening of the centennial celebration of the College of Engineering of that University. The Conference is arranged each year by an informally organized group, mainly administrators of research and development in the physical sciences. Attendance is by invitation and proceedings are published by the host university. The programme for 1954 was designed for discussing specific incidents pertaining to management of the 4,000 million dollar research and development business throughout the United States.

At each half-day symposium a series of four or five brief presentations was followed by lively discussion. The first symposium, "Appraising and Rewarding the Researcher's Output", was opened by Dr. Eric A. Walker, dean of engineering at Pennsylvania State College, where the Conference was founded in 1947. Observing that "we have passed through the stage of random creativeness and entered an age of deliberate creativity", Dr. Walker said it is up to the research man to sketch the course the engineer will follow toward the prophesied increase of 100,000–150,000 million dollars in the gross product of the United States by 1960. Although no objective measure of an individual scientist's productivity has yet been found, the fact that empirical evaluations are becoming more prevalent and systematic was brought out by each speaker.

Mr. Edwin A. Speakman, general manager, Guided Missiles Division, Fairchild Engine and Airplane Corporation, described the semi-annual rating plan of his company. He noted that supervisors and administrators must often evaluate and reward a researcher's potential far in advance, as it may take several years for his efforts to materialize. Dr. Clyde E. Williams, director of the Battelle Memorial Institute, emphasized that scientific integrity, selflessness and ability to work in a team are considered most important for promotion. The National Bureau of Standards, according to its director, Dr. A. V. Astin, favours appraisal and promotion of staff members through the collective judgment of committees at various levels. Although it is possible to promote a scientist to the highest grade without assigning him executive responsibility, such assignments are difficult to avoid, and Dr. Astin suggested that this situation warrants further study.

The Conference speaker from outside the United States was Dr. John J. Green, of the Defence Research Board of Canada, who is science advisor to the Royal Canadian Air Force. He summarized, with individual examples, awards which are available for merit in research; these include sabbatical years, cash awards, royalties from inventions, the Queen's honours lists, and the annual gold medal of the Professional Institute of the Civil Service of Canada.

After a luncheon, addressed by Henry T. Heald, chancellor of New York University, the second symposium dealt with a number of general aspects of "Management in the Research Laboratory". The chairman, Dr. James B. Austin, vice-president of the Research Division, United States Steel, gave some pointers on the "Control of Service Groups". He emphasized the concept of service to the research staff, pointing out that machine-shop backlog must be small enough to accommodate rush-work for scientists. Informal contacts by the scientist with the service technician are encouraged and priority determinations in shops work, for example, are made through weekly conferences. In exploring "The Use of Work Simplification in a Research Laboratory", Mr. Allan H. Mogensen, management consultant, gave examples of how other organizations have been helped by such a programme. He urged that all workers be taught to keep asking 'why', and recommended direct communication, rather than suggestion boxes, as the channel for ideas.

The delicate problem of "Inter-Departmental Relations of Research to Production and Sales" was treated by Mr. Kenneth H. Klipstein, general manager of the Research Division, American Cyanamid Co. Not only individuals but also whole sections of an organization must practise team-work in to-day's industry and government. To have the research director as a part of top management and to use co-ordinating committees for active planning and review are approaches Mr. Klipstein has found most effective. Similar experience was described by Dr. Blaine B. Wescott, executive vice-president, Gulf Research and Development Co. Having research consolidated in one department rather than dispersed among operating departments, he agrees, has more advantages than disadvantages. Qualifications of an engineering manager were discussed by Mr. Howard L. Richardson, vice-president of engineering operations, Sylvania Electric Products, Inc. No stereotyped combination of traits has been found, he pointed out. A technical background is invaluable, but it does not teach such executive arts, as how to sell ideas and how to make decisions based on judgment where facts are sparse.

In the third symposium, "Communication Problems in a Research Operation" were illustrated. The chairman of the session, Dr. Paul R. Beall, consultant to the Deputy Chief of Staff, Development, U.S. Air Force, was also chairman of the Conference Programme Committee. Alluding to the disappointment a company may experience when inadequate communication of a design proposal makes it lose a large contract, Dr. Beall gave some tips, including a dramatized presentation on how to make an effective oral presentation. "How ASTIA Can Help Your Research" was indicated in a series of specific cases by Mr. Leslie E. Neville, director of the Armed Services Technical Information Agency (ASTIA). This Agency is a clearing-house available to the U.S. Defense Department and its prime contractors. A single report, for example, obviated a long-range study of corrosion which saved one company fifty thousand dollars and two years in time.

Dr. Howard G. Vesper, vice-president of the Standard Oil Co. of California, asserted that good external communication with its clientele is at the heart of effective service by a research laboratory. He agreed with the thinking of Dr. Wescott and Mr. Klipstein as regards a separate laboratory organization and its co-ordination through committees. At California Research, Inc., a conscious attempt is made to bring group leaders and even bench workers into study-group discussions, and also to permit them to see their 'brain children' put on the production line. A very specific tool of communication is "The Director's Mimeographed Weekly Bulletin", described by Dr. Helmut E. Landsberg, chief of the Climatological Services Division, U.S. Weather Bureau. It helps to bridge the gap resulting from bigness.

The special problems of "Communication in Classified Research", brought up again and again during the Conference, were given more extensive treatment by one in a position to know, Dr. Norris E. Bradbury, director of the Los Alamos Scientific Laboratory of the Atomic Energy Commission. The solution of internal communication problems, he said, is really a function of how the director and the people with whom he works feel toward one another. No tools or procedures can compare with 'attitudes' when it comes to communication. The 'need to know' is interpreted broadly within Los Alamos, and free discussion among staff develops bright ideas in the most unexpected places. In external communication, security restrictions cause difficulties that Dr. Bradbury does not know how to overcome. He believes there can be more common sense in the sharing of scientific information without endangering national security.

The fourth symposium, on "Physical Facilities for Research", included contributions from Mr. Walter H. Verdier on the planning and construction of the new Applied Physics Laboratory of Johns Hopkins University; from Mr. A. R. Johnson, of Arthur D. Little, Inc., on the building of adequate laboratory structures for less than 12 dollars per sq. ft.; from the architect, Mr. Ralph Walker, who spoke from wide experience on "Designing Buildings for Research"; and from Dr. Clifford F. Rassweiller, vice-president for research and development, Johns Manville Corporation, on "Building for Greater Research Productivity". All agreed that the building is merely a tool for productive research. There were some differences of opinion about the size of the 'modular design' and about how easily transferable the partitions should be. Dr. Rassweiller particularly emphasized thinking in terms of things that will increase research productivity. We should not just ask "How much can we save in building?", he declared, but "How can we build a facility that will give greatest returns on the dollars invested?".

The final symposium, on "Basic Research in an Applied Research Laboratory", elicited stimulating discussion to the very end of the Conference. The chairman of the session, Mr. Earl P. Stevenson, president of Arthur D. Little, Inc., had served this year as general chairman of the Conference Advisory Committee. He strongly favoured the mixing of some basic research along with applied, and explained how his company established the 'office of science director' with no administrative responsibility but with a broad mandate for providing scientific leadership through the informal organization. Dr. Maurice Nelles, director of the Borg-Warner Central Research Laboratory, gave a concrete example of how basic results grew out of applied research on sheet metal work. "We used to be asked", he said, "what have you discovered that is new? Now we are asked, when will you complete that project?" This signifies, Dr. Nelles concluded, that science may have reached the end of progress by analysis and separation—that random hunting has passed its prime—and we must plan deliberate creation and synthesis. "Cortisone—A Product of Joint Academic and Industrial Basic Research" was the title of a vivid description by Dr. Randolph Major, vice-president of Merck and Co., Inc. Without close team-work between applied and basic approaches, the hormone synthesis which resulted in this drug could never have been possible.

Dr. Ralph Bown, vice-president of the Bell Telephone Laboratories, suggested that "Research is simply an effort to understand more about things". The way for an applied laboratory to get a balance which includes some basic research is to employ people who are concerned in understanding the things which interest the company and then to keep them informed of those interests. Bell Laboratories, Dr. Bown said, relies less on committees and more on delegation and co-ordination through the line than seems to be true of some others. When a man has a bright idea, the general policy is that he should pursue it, if it is reasonably applicable to the company's work; as soon as it reaches the stage where it is not, he should publish interim results so that someone else can continue the research.

Mr. Alex Stewart, director of research of the National Lead Co., spoke on "Gold is where you find It", in people as well as in minerals. His company sponsors exploratory and basic research in universities and, when timely, transfers it to the company laboratory. Also, the National Lead Co. has the unique practice of making a research and development team actually demonstrate the salability of a proposed product before it is turned over to the Sales Department.

At the dinner meeting, Major General William M. Creasy, of the Army Chemical Corps, spoke candidly of needs and proposals for strengthening the research and development work as well as general operations of his Corps. He is setting up an advisory committee and has engaged a leading industrial scientist to direct all scientific operations.

Attendance at the Conference was reported to be a little more than half from industry and the remainder divided equally between government and universities. The 1955 Conference will be held at Northwestern University, Evanston, Illinois. Dr. Thomas H. Vaughn, vice-president for research and development of the Colgate-Palmolive Company, is the new chairman of the Advisory Committee, and Dr. Maurice Nelles the new chairman of the Programme Committee.

INDIAN ASSOCIATION FOR THE CULTIVATION OF SCIENCE

REPORT FOR THE YEAR 1953–54

THE annual report for 1953–54 of the Indian Association for the Cultivation of Science has recently been published in full*, and although reference has already been made in these columns to the Association's activities during the year (*Nature*, September 11, p. 495) when the acting director, Prof. P. Ray, originally presented the report at the annual general meeting of the Association, held on July 30, a fuller résumé that is now possible, from the published report, is not without interest. Besides the usual appended financial statements and lists of books acquired during the year and serials received on an exchange basis, the account includes, among the departmental reports of research, departmental lists of papers published during the year. Details are given of the five-year plan of development covering the financial years 1954–59, which was prepared at the request of the Finance Committee and the Government of India and finally approved by the Council on March 29, 1954. The plan contemplates non-recurrent grants totalling Rs. 1,138,200 for equipment and Rs. 1,771,393 for land and buildings, of which two-thirds is to be provided by the Government of India and one-third by the Government of West Bengal. Recurrent grants, which are estimated to increase from Rs. 465,630 in 1954–55 to Rs. 777,415 in 1958–59, and to total Rs. 3,237,592 in the quinquennium, will be provided mainly by the Government of India as at present. The Plan does not involve the establishment of any new Department.

In the Department of General Physics, X-Rays and Magnetism, investigations on the transport properties of matter have been started. Results obtained for the conductivity of argon–neon mixtures using Kannuluik's thick-wire method agree with the 12 : 6 power model of the intermolecular potential but not with the inverse power model. B. N. Srivastava has applied the theory of the thermodynamics of irreversible processes in investigating the thermal effusion of substances capable of existing in two isomeric forms. The unit-cell dimensions of fluoranthrene and phthalic acid have been determined from morphological and X-ray studies, and the dimensions of the intermicellar zones of some fibres have been obtained by incrustation of metals like gold and silver in the colloidal form in the fibre framework. The investigation of low-angle X-ray scattering continued as well as X-ray studies of red-coloured silver glass and of the nature of adherent metal films of glass surfaces. Determinations of the magnetic anisotropy of paramagnetic crystals of the elements of the iron group continued, and a new, simple and efficient electrodynamic method of measuring magnetic fields, with an accuracy of about 5 parts in 10,000, has been developed. Experimental and theoretical studies on the electrical, thermal and magnetic properties of graphite crystals also continued.

In the Department of Optics, the ultra-violet absorption spectra of phenetole, *n*-butyl benzoate, α-chloronaphthalene and α-bromonaphthalene have been determined in the liquid and solid states at low temperatures and also those of *o*-, *m*- and *p*-toluidine, while the Raman spectra of *o*- and *p*-chlorotoluene in the solid state at − 180° C. have been compared with those for the liquid state. Studies of the Raman spectra of 1 : 2-dichloroethane and 1 : 1 : 2-trichloroethane in the vapour state indicate a marked change in the ratio of the number of the two types of molecule with the change from liquid to vapour state, attributed to the influence of the strong inter-molecular field in the liquid state. The absorption of radio waves of frequencies in the range 250–920 Mc./s. in benzyl alcohol, benzyl chloride and benzylamine at different temperatures has also been studied, as well as the absorption of 3·3-cm. microwaves in chloroform and ethylene dichloride. The number of events in which a neutral particle in cosmic rays produced in a lead absorber either one charged meson or more neutral ones moving along different paths was determined.

In the Department of Theoretical Physics the equivalence of the Born approximation to the covariant perturbation theory has been demonstrated by considering the scattering of fast electrons by the Coulomb field of the atomic nuclei, and the method of Brinkman and Kramers has been extended to the capture of the electron in arbitrary excited orbits. Theories of the nuclear shell structure model and Bohr's liquid-drop model are being studied with the view of finding common ground for the two approaches.

In the Department of Physical Chemistry, investigations on the chain transfer of vinyl acetate using hydrocarbons, alcohols, ketones and chlorinated solvents gave results in agreement with the α-hydrogen theory. With acrylonitrile the results also agree with that theory except when halogenated solvents are used. A study of the kinetics and chain-transfer coefficients of vinyl and other monomers in the hydrogen peroxide-catalysed systems has led to a method for evaluating solvent transfer in the catalysed system. Work with nine azonitriles as initiators in the polymerization of vinyl monomers was completed, and work on the synthesis of hydroperoxides and the X-ray-initiated polymerization of vinyl monomers commenced. Lauroyl, caprinyl and caproyl esters of methylethylcellulose have been prepared. Seven osmometers have been constructed and calibrated for the determination of the molecular weight of co-polymers. Results obtained for the molecular weight distribution of polystyrene were in good agreement with the theoretical distribution equation of high polymers deduced by S. R. Palit and K. C. Majumdar. The solubility of anthracene and phenanthrene in the binary systems ethyl iodide or iodobenzene, cyclohexane or cyclohexene, has been determined.

---

* Indian Association for the Cultivation of Science. Annual Report for 1953–54. Pp. 64. (From the Association, Jadavpur, Calcutta, 1954.)

Work in the Department of Organic Chemistry has been reoriented considerably. In the study of diterpenoids a new general method has been developed by the synthesis of tricyclic C_1-ketones. A new stereo-specific synthesis of *dl*-homocamphoric acid has been developed from camphononic acid and a similar synthesis of *dl*-homoapocamphoric acid completed. Efforts are also being made to develop a stereospecific synthesis of a steroidal nucleus, and the technique using liquid ammonia for the preparation of intermediates has been improved. A synthesis of the dicarboxylic acid, $C_{12}H_{14}O_4$, obtained by the degradation of picrotoxin, has been achieved, and the ultra-violet absorption spectra of benzo-α- and γ-pyrones correlated with the corresponding chromophoric structures.

The Department of Inorganic Chemistry has been concerned chiefly with the chemistry of co-ordination complexes, especially the *cis-trans* isomerism of copper complexes, and with the use of organic reagents for inorganic analysis. A critical review is in progress of colorimetric methods for the determination of titanium, chromium, uranium and palladium, and a new method has been developed by the colorimetric determination of titanium with salicylhydroxamic acid, while salicylamidoxime has been used for the gravimetric determination of transitional elements, as well as for their separation and the colorimetric determination of uranium and iron.

LAW OF RED SHIFTS AND THE DISTANCES OF NEBULÆ

THE George Darwin Lecture of the Royal Astronomical Society was delivered by the late Dr. Edwin Hubble on May 8, 1953, in the Society's rooms at Burlington House, London, the subject of the Lecture being the law of red shifts—the correlation between distances of nebulæ and displacements in their spectra*. Three phases in the history of the law of red shifts were discussed; the first, the discovery phase, commenced with Slipher's measurement in 1912 of the velocity of *M* 31, which he found to be −300 km./sec., and during the next ten years he contributed forty-two out of forty-six nebular velocities then available. The list was completely dominated by large positive velocities which ranged up to 1,800 km./sec. in the case of *NGC* 584.

Attempts from 1916 onwards to derive the solar motion with respect to the nebulæ were frustrated by the positive signs indicating general recession, but improvements in the results followed Wirtz's introduction of a constant *K* term in the equations. Although the improvement was not sufficient to render the results acceptable, it was seen that the next logical step would be to replace the constant *K* by *rK*, that is, by a term which varied with the distances of the individual nebulæ; and during the early and middle twenties various solutions were made, measures of relative distances being based on apparent luminosities and apparent diameters. Failure was due, as appeared later, to the relatively short range covered by the radial velocities being insufficient to give reliable individual distances. The problem was finally solved when the brightest stars in late-type spirals and irregular nebulæ were established as suitable indicators of distance and were calibrated by Cepheids in a few of the nearest nebulæ. Using the upper limits of brightness of these stars as a distance criterion and applying it to the nebulæ with measured velocities, the law of velocity-distance shifts, now known as the law of red shifts, emerged approximately in its present form. This law was established in 1928 out to about seven million light-years, as an approximate linear relation according to which velocities of recession increased at the rate of the order of 500 km./sec. per million parsecs of distance, or about 150 km./sec. per million light-years.

The second phase, a Mt. Wilson project, lasted from 1928 to 1936, during which Humason assembled spectra of nebulæ and Hubble attempted to estimate their distances. For various reasons, attention was concentrated on clusters, and, when these could not be observed to advantage, spectra of field nebulæ, isolated or members of small groups, were assembled in large numbers; these data provided an account of red shifts in the nearer, more conspicuous nebulæ of all kinds. The results of the second phase were as follows. The law of red shifts appeared to be linear, and the red shifts increased at the rate of about 160 km./sec. per million light-years. The solar motion was largely accounted for by galactic rotation, and the residual represented the peculiar motion of the stellar system and was small and uncertain, of the order of 100–150 km./sec. towards galactic latitude + 30° approximately, and longitude in the quadrant 50°–140°. The law of red shifts did not operate within the Local Group; and, lastly, magnitude–velocity relations, fitted to data for clusters, resolved nebulæ and field nebulæ, and displaced from one another by magnitude intervals indicating relative absolute luminosities, could be used to calibrate all the relations in terms of brightest stars.

In the interim between the second and third phases, Mayall began assembling spectra with a very fine ultra-violet spectrograph on the 36-in. Crossley at Mt. Hamilton, and gave special attention to the later-type spirals and other systems of low surface brightness for which his reflector was as efficient as the larger telescopes on Mt. Wilson. His list now numbers about 280 nebular velocities and with Humason's list, when the two are published, will total about 750 individual nebulæ. The data furnish most important information of every kind, and full discussion must await publication of the lists, though certain matters are divulged by Hubble; limits of space prevent anything more than reference to them in this article.

The completion of the 200-in. reflector and its accessories initiated the third and current phase of the development, the programme of which has two parts, the first being the extension of the observed range. During the first season that a nebular spectrograph could be used on the 200-in. (1950–51), Humason obtained spectra in three clusters which had been unsuccessfully tried with the 100-in.; one of these, the Hydra cluster, had a velocity of 61,000 km./sec. The 48-in. Schmidt reflector can be used to this limit, but beyond it clusters cannot be identified with certainty on the survey plates. Humason is confident, however, that velocities up to 75,000 km./sec. at least can be recorded when clusters have been located, but such locations would depend on purely chance finds with the 100-in. and 200-in.

The second part of the programme deals with the revision of the distance scale. A review of the unit of distance has been pending for more than twenty years—after it was realized that many novæ and globular clusters in *M* 31 were fainter with respect to the Cepheids than was the case in our own system. It is now known that the classical Cepheids in *M* 31 are nearly 1·5 magnitudes brighter than was previously supposed; in consequence, current estimates of absolute distances must be nearly doubled, and the so-called 'age of the universe' must be increased on the same scale. Among other steps in the programme are included the setting up of faint-magnitude sequences in Selected Areas, the measurement of nebular magnitudes, corrections for effects of red shift on apparent magnitudes, and the examination of the possibility of errors arising from inter-nebular obscuration and systematic evolution changes in luminosities during the travel time of the light from the nebulæ. Each of these is considered in logical order in the later part of the Lecture, which ends with a warning that "we are already in the region of diminishing returns"—in other words, instruments will be increasingly expensive and progress increasingly slow. So far as the immediate future is concerned, the most promising programmes accept the observable regions as now defined, and, while hoping for only modest extensions in space, concentrate on increased precision and reliability in the recorded description. "The reconnaissance is being followed by an accurate survey; the explorations are pushed towards the next decimal place instead of the next cipher." The Lecture ends with an optimistic outlook: "From our home on the Earth, we look out into the distance and strive to imagine the sort of world into which we are born. Today we have reached far out into space. Our immediate neighbourhood we know rather intimately. But with increasing distance our knowledge fades, and fades rapidly, until at the last dim horizon we search among ghostly errors of observations for landmarks that are scarcely more substantial. The search will continue. The urge is older than history. It is not satisfied and it will not be suppressed".

ABSORPTION OF IONS BY PLANTS

By D. REICHENBERG
Chemical Research Laboratory, Teddington
and J. F. SUTCLIFFE
Botany Department, King's College, London

It has been shown[1] that in water culture some plants may absorb both cations and anions at a rate which is independent over a wide range of the total concentration in the culture medium, provided their relative concentrations in the medium are kept fixed. Such results may be explained on the basis that the rate of absorption is limited either by the number of suitable 'carrier' molecules or by the amount of energy available from respiration[2]. However, recent work has shown that ion exchange processes may follow a closely similar pattern. The rate of exchange of sodium for hydrogen on both strong-[3] and weak-acid[4] cation exchange resins has been shown to be independent of the sodium ion concentration in solution over a wide range. In this range, the rate-controlling process has been shown to be the diffusion of ions through the resin material, the constancy of rate being due to the fact that the *boundary* concentrations are independent of those in solution. It appears, therefore, that a simple alternative hypothesis for the uptake of ions by plants may be postulated on the basis of ion exchange.

The assumption must be made that there is present in plant cells a membrane (or membranes) containing both anion- and cation-exchange materials across which the movement of ions occurs. However, it is not necessary to postulate two entirely homofunctional substances, one completely acidic and the other completely basic; only that one is predominantly acidic and the other predominantly basic. The two might even be part of the same protein molecule provided the acidic and basic units were sufficiently segregated. The properties of such 'mosaic membranes' have been studied, both theoretically and experimentally, by Sollner[5,6]. To cause ion exchange to proceed it is necessary for the plant to provide on the inside of the membrane a continual supply of an appropriate electrolyte such as carbonic acid or some other weak organic acid. The cations would then be exchanged for hydrogen ions on the cation exchange material, and the anions likewise for bicarbonate (or other anion) on the anion exchanger. Thus the hydrogen ions and anions would diffuse separately through the cation and anion exchange materials respectively and recombine in the culture medium, while other ions from the medium would move in the opposite direction. It is known that hydrogen ions, bicarbonate and other anions are, in fact, yielded by plants to the external solution.

The energetics of transport by ion exchange diffusion are particularly simple and account readily for the fact that ions may be absorbed against a concentration gradient. Consider a cation exchange membrane separating infinite volumes of solutions 1 and 2, in which the activities of sodium and hydrogen ions are, respectively, $[a_{\mathrm{Na}}]_1$, $[a_{\mathrm{H}}]_1$, $[a_{\mathrm{Na}}]_2$, $[a_{\mathrm{H}}]_2$. 1 represents the culture medium and 2 the solution on the inside of the plant membrane. Sodium will diffuse through the membrane from solution 1 to solution 2 provided that the concentration of sodium ions *in the membrane* is greater on the side nearer solution 1. Since the uptake of sodium ions by cation exchange materials of both the strong- and weak-acid type has been shown to depend on the ratio $a_{\mathrm{Na}}/a_{\mathrm{H}}$ (if hydrogen is the competing ion), transport of sodium ions from solution 1 to solution 2 will occur if:

$$\frac{[a_{\mathrm{Na}}]_1}{[a_{\mathrm{H}}]_1} > \frac{[a_{\mathrm{Na}}]_2}{[a_{\mathrm{H}}]_2} \qquad (1)$$

that is, if

$$\frac{[a_{\mathrm{H}}]_2}{[a_{\mathrm{H}}]_1} > \frac{[a_{\mathrm{Na}}]_2}{[a_{\mathrm{Na}}]_1} \qquad (2)$$

Now consider the energetics of the process. Let $[a_{\mathrm{Na}}]_1$ be less than $[a_{\mathrm{Na}}]_2$. This means that sodium ions must be transported against a concentration gradient. For this an expenditure of free energy $RT \ln \frac{[a_{\mathrm{Na}}]_2}{[a_{\mathrm{Na}}]_1}$ per gm. ion is required. However, hydrogen ions will diffuse in the opposite direction assisted by their own concentration gradient which provides an amount of free energy $RT \ln \frac{[a_{\mathrm{H}}]_2}{[a_{\mathrm{H}}]_1}$ per gm. ion. This will be sufficient to drive the sodium ions across provided

$$RT \ln \frac{[a_H]_2}{[a_H]_1} - RT \ln \frac{[a_{Na}]_2}{[a_{Na}]_1} > 0,$$

which reduces to the inequality (expression (2)) above. It is therefore necessary for the hydrogen ion concentration inside the membrane to be raised through metabolism to a value satisfying the conditions of expression (2) if the absorption of sodium against a concentration gradient is to occur. In a similar manner the absorption of anions requires a suitably high concentration within the plant of carbonate or bicarbonate ions or anions of an organic acid.

In the respect that it depends upon metabolically maintained gradients of exchangeable ions this hypothesis resembles those of Brooks[7], and Osterhout[8], which were criticized by Hoagland[9], on the grounds that the necessary gradients either do not always exist or bear no direct relationship to the rate of ion absorption. A critical point in this connexion appears to be the precise location of the effective membrane in a vacuolated cell, whether it is to be represented by the whole protoplast or by the outer or inner surface membrane. Clearly, if the whole protoplast is involved the ion exchange mechanism cannot operate unless gradients exist for hydrogen ions and suitable anions between the external medium and vacuolar sap. Hoagland claimed that ions may be absorbed when these conditions do not apply, and therefore rejected the exchange hypotheses.

On the other hand, if the outer cytoplasmic surface acts as the membrane, it is evident that respiratory processes in the protoplasm may create the necessary gradients and accumulation of ions in this region be brought about. With meristematic cells in which there are no obvious vacuoles this mechanism is sufficient to account for absorption. It has generally been supposed that ions move passively into the protoplasm of plant cells[2,10-12], but clearly the presence of metabolic products in the form of charged particles is an essential pre-requisite, since diffusion alone is insufficient and adsorption-exchange reactions are obviously involved. Frey-Wyssling[13] has suggested a structure for the surface membrane of a protoplast which is not inconsistent with its possession of ion exchange properties.

With mature cells, however, ions accumulate in the free state within the vacuoles, and in so doing an additional barrier, the tonoplast, is encountered. Since metabolic reactions are on the whole occurring outside this membrane it seems unlikely that the necessary gradients for hydrogen ions and anions will exist to account for movement from the protoplasm. It is probable, therefore, that in this case a mechanism other than ion exchange is responsible for transport. A discussion of the possibilities in this connexion is outside the scope of the present communication; but a mechanism based on the ideas of Goldacre[14] or Conway[15] would appear to be adequate. In support of the hypothesis that the movement of ions across the plasmalemma and tonoplast are accomplished by fundamentally different processes, Arisz[16] has shown that whereas chloride transport into the protoplasm of *Vallisneria* leaves is inhibited by cyanide it is unaffected by dinitrophenol at a low concentration which prevents vacuolar accumulation. Moreover, Steward[17] has claimed that the mechanism of absorption of ions by meristematic tissue-culture cells is not identical with that of cells in the vacuolated condition, and this may be interpreted as above.

If two distinct mechanisms are involved in the transport of ions from an external medium into the vacuoles of individual cells or the stele of the root, then either may be the limiting factor according to the particular environmental or experimental conditions involved. The work with resins suggests that contrary to general opinion the rate of ion exchange in a preliminary phase may control the rate of absorption of mineral salts by the plant as a whole. Recently Epstein[18] has advanced the view that active transport of both anions and cations requires their combination with protoplasmic constituents, a view consistent with our own.

One of us (D. R.) wishes to thank the Director of the Chemical Research Laboratory for permission to publish this communication.

FINDING THE DIRECTION OF TRAVEL OF SEA WAVES

By N. F. BARBER

Geophysics Division, Department of Scientific and Industrial Research, Wellington, New Zealand

TO describe the nature of wind waves, or to locate a storm by observations of swell, it is necessary to be able to distinguish waves by their direction of travel. The study of period[1] is insufficient by itself.

Some preliminary experiments have been made in the Waitemata Harbour, Auckland, measuring wave direction by the correlogram. The photographs of Fig. 1 show statistical relations between wind waves of period near 2 sec. at points separated by distances of 2, 9, 18 and 27 ft. along a fixed line. From them may be obtained the curve of Fig. 2, showing how the energy is distributed among the various directions of travel. The wind was about 15 knots and 2-sec. waves were dominant; but because the fetch in the wind direction was much greater than elsewhere, it is not expected that the curve of Fig. 2 will apply to open water.

The elevation in a sinusoidal wave train may be written:

$$\text{elevation} = \text{real part of } a \exp i(lx + my - \sigma t),$$

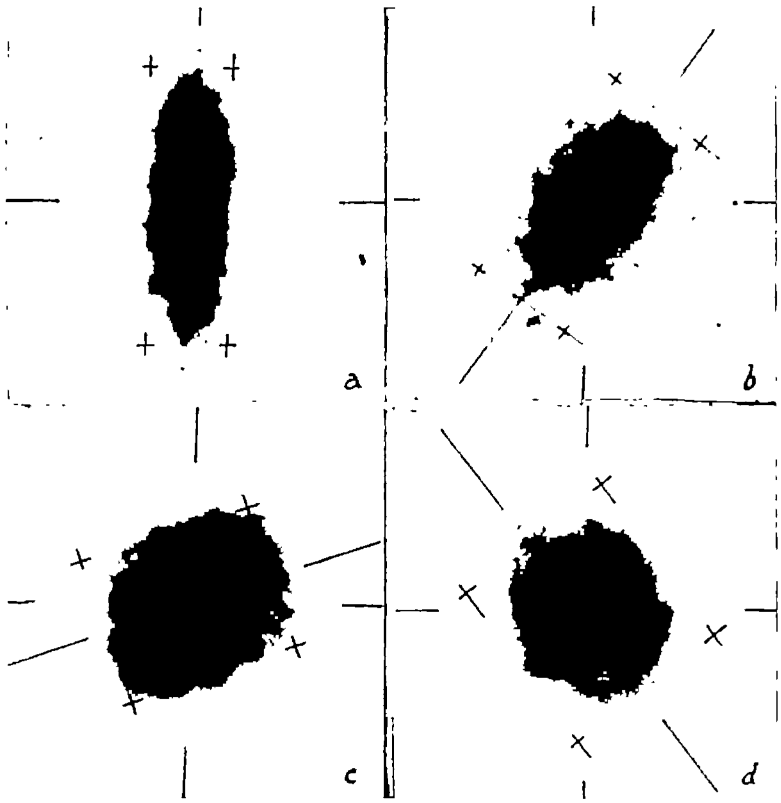

Fig. 1. Photographs showing the statistical phase relations between waves at points separated by 2, 9, 18 and 27 ft. along a fixed line. Attention is confined to waves of period near 2 sec.

where a is the amplitude, σ the frequency, and l, m are wave numbers in rectangular directions x, y. Khintchine's theorem[2] relating the energy spectrum $E(l, m)$ of a more complicated wave system with its autocorrelogram $R(x, y)$ then becomes[3]:

$$R(x, y) = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} E(l, m) \exp i(lx + my)\,dl\,dm. \quad (1)$$

In progressive incoherent waves, $R(a, b)$ is obtainable as the covariance of complex wave elevations at two fixed points separated by distances a, b, the average being taken over a long time.

It was desired to restrict the wave measurements to discrete points upon a line taken as the x-axis. Such results can give E so long as attention is restricted to waves very near some frequency σ_0 with corresponding wave-length $2\pi/k_0$. It then appears, to a sufficient approximation, that equation (1) inverts to a Fourier series:

$$E(k_0, \theta) = E_0 \sin\theta\,[\tfrac{1}{2} + \sum_{n=1}^{\infty} C_n \cos(nlD - \psi_n)], \quad (2)$$

where θ is $\cos^{-1} l/k_0$, the direction of wave progress relative to the line of recorders, $E(k_0, \theta)\delta\theta$ is the energy of waves with number k_0 and directions between θ and $\theta + \delta\theta$, and C_n, ψ_n are the modulus and phase of the complex correlation coefficient between wave elevations at points separated by a distance nD. The distance D should not exceed π/k_0 or half a wave-length. The expression is valid so long as no waves have directions outside the range 0°–180°. The factor $\sin\theta$ is an approximation the error of which causes an under-estimate of the wave energy in directions near 0° and 180°.

In the experiment, each detector was a pair of parallel vertical copper strips, partly immersed in the sea and fed with 2 volts (mains frequency) from a transformer. The current that passed was proportional to the depth of immersion, varying with the waves, and a corresponding voltage signal was conveyed to the analyser. Two such instruments were hung from a pile wharf at separations of 2, 9, 18 and 27 ft. in succession.

A pendulum of period near 2 sec. was used to select a narrow frequency-band and to produce the pictures in Fig. 1. Its free motions in all azimuths had equal period and damping, and it was electrically driven through amplifiers fed with the wave signals. The motion of the pendulum was recorded optically as a spot of light moving over a photographic plate, an exposure of 15 min. being required for each of the pictures in Fig. 1.

The electrical arrangements were such that a coherent signal $P \cos \sigma_0 t$ from one instrument would give the pendulum a circular motion in the positive sense, that is, $P \exp i\sigma_0 t$ if the picture is thought of as an Argand diagram. From the other instrument, that at the smaller x-value, a signal $Q \cos \sigma_0 t$ would give a motion in the opposite sense, or $Q^* \exp - i\sigma_0 t$. In natural incoherent waves the amplitudes P and Q are complex quantities changing slowly and randomly in magnitude and phase, and have equal variance. The modulus C and the phase ψ of their complex correlation coefficient may be deduced from the elliptic form of the photographic record:

$$C = (A^2 - B^2)/(A^2 + B^2),$$

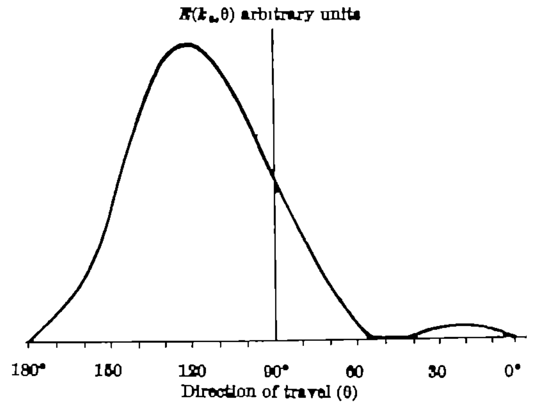

Fig. 2 Distribution of wave-energy with respect to direction of travel relative to the line of instruments. The curve is deduced from the records in Fig. 1

where *A*, *B* are the principal diameters and $\frac{1}{2}\psi$ = azimuthal angle of the major axis. To make its form more obvious, each record was taken on an emulsion having a high contrast.

The $E(k_0, \theta)$ curve in Fig. 2 was computed from the last three photographs in Fig. 1. It shows that the highest waves are travelling in the direction 120° to the positive sense of the line joining the instruments. This was, in fact, the direction of the wind at the time of the measurements, so the method has given reasonable results.

An improved apparatus is being built for further work. With some changes in experimental detail the method appears suitable for a shore-based observatory studying ocean waves. It appears preferable to the better-known 'phase' method in which detectors are combined into a directional array. One advantage is that equal resolving power is obtained with fewer underwater instruments.

It is worth noting that no account need be taken of wave refraction at a coast, so long as its underwater contours are straight and parallel to the line of instruments. The deep-water directions may be inferred without reference to the tidal changes of depth or stream. Further, Longuet-Higgins has shown (personal communication) that only a few terms in (2) are needed to resolve swells the directions of which are well defined. [July 23.

SIMULTANEOUS DETERMINATION OF SODIUM, POTASSIUM, CALCIUM, MAGNESIUM AND STRONTIUM BY A NEW MULTICHANNEL FLAME-SPECTROMETER

By DR. BERT L. VALLEE

Biophysics Research Laboratory of the Department of Medicine, Peter Bent Brigham Hospital and Harvard Medical School, Boston, Massachusetts

SODIUM, potassium, calcium, magnesium and strontium have been found universally associated with living matter. The osmotic effect of these elements, their interaction in enzyme-substrate reactions, their participation in intra- and extracellular processes and their formation of salts and chelate complexes with biological substances have been studied intensively. The development of flame-photometry for the analytical assessment of these elements has been decisive in accelerating the understanding of their biological function.

We have recently completed the design and construction of a direct-reading multi-channel flame-spectrometer for the simultaneous analysis of sodium, potassium, calcium, magnesium and strontium. The design allows of the addition of recording equipment to determine additional elements[1]. The instrument, as at present constituted, combines an oxy-hydrogen burner (Beckman No. 4020) with a Wadsworth stigmatic mounting grating spectrograph (Jarrell-Ash Co.). The grating has an effective surface of $3\frac{1}{4}$ in. × $1\frac{1}{4}$ in., 15,000 grooves to the inch, a radius of curvature of 1·5 m. and a reciprocal linear dispersion of 10·8 A./mm. in the first order. Five photomultiplier tubes provided with power supplies for low and high voltage and d.c. amplifiers are placed at the focal plane of the grating. 1P28 photomultiplier tubes (Radio Corporation of America) are placed on the Mg line at 3838·258 A., the CaO band-head at 5495 A., the Na line at 5889·953 A., and the Sr line at 4607·331 A. A 1P22 photomultiplier tube (Radio Corporation of America) is placed on the K line at 7664·907 A. The entrance and exit slits are 0·4 mm. wide. Microammeters, calibrated to read from 0 to 200 μamp., serve at present as recorders for each channel. Control for null and sensitivity adjustments is provided for.

Calibration curves obtained for all five elements are linear over a range of 1–1,000 times the initial concentration, and 1–3 per cent precision is achieved (Fig. 1). The present limits of sensitivity are as follows: sodium, 0·01 p.p.m.; calcium, 0·1 p.p.m.; potassium, 0·2 p.p.m.; magnesium, 0·3 p.p.m.; strontium, 0·1 p.p.m. No internal standard is employed.

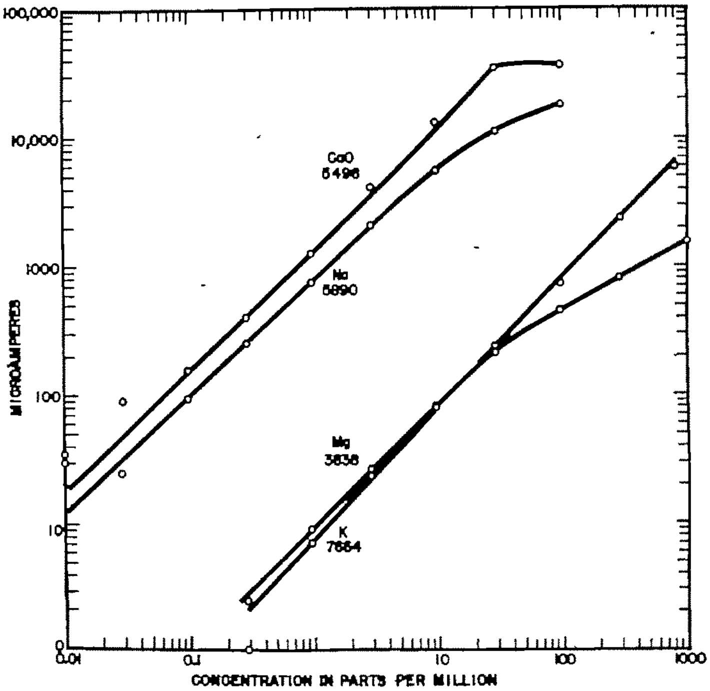

Fig. 1. Calibration curves for calcium, sodium, potassium and magnesium. The receivers were set at the wave-lengths indicated

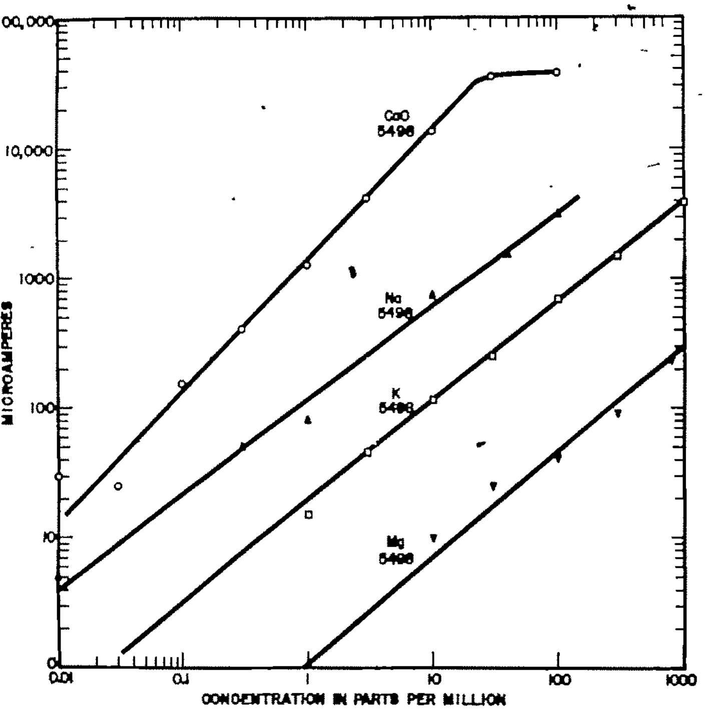

Fig. 2. Rising concentrations of calcium, sodium, potassium and magnesium, all measured with photomultipliers at 5495 A.

Many observers have noted the effect of variable quantities of one or several of these elements upon the measurable light intensity elicited from another. This phenomenon, referred to as 'interference', covers various effects of extraneous, dissolved materials on the monochromatic radiation attributable to the test substance. This 'interference' has been variously attributed to alterations in "the rate of fluid aspiration into the burner", preferential excitation of an 'interfering' element in the flame, the "rate of propagation of the flame"[2], "photochemical effects"[3], the inadequate resolution of monochromatic light "or other defects in the optical system"[4].

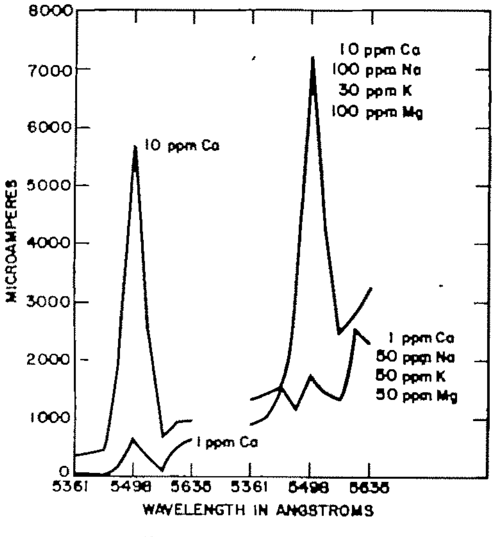

Fig. 3. Left: a solution containing calcium, in the concentrations indicated in the graph, was used. Right: similar measurements of calcium, carried out in the presence of an excess of sodium, potassium and magnesium

Internal standardization and dilution of samples have been recommended and used empirically and remedially with limited success. The removal of interfering ions from complex substances of unknown composition has been recommended as the only means of obtaining accurate results[5].

Our investigations indicate that the effect of these cations upon one another can be attributed to the superposition of their monochromatic emission upon heterochromatic background radiation. The background increases in direct proportion to the concentration of each radiating species. Fig. 2 shows the response of the calcium receiver, at 5495 A., to increasing concentrations of calcium, sodium, potassium and magnesium. Sodium, potassium and magnesium contribute heterochromatic background radiation to the calcium receiver. The absolute quantity of background differs for sodium, potassium and magnesium, but the slopes of their contributions are identical and additive.

In a corroborative experiment the photomultiplier tube was moved stepwise from background radiation at 5361 A. to background radiation at 5635 A. across the CaO bandhead at 5495 A. Results for 1 and 10 p.p.m. of calcium alone and in the presence of large excesses of sodium, potassium and magnesium are shown in Fig. 3. Emission, as shown by the right-hand curves, is raised above that shown by the left-hand curves due to background, attributable to the extraneous cations. Subtraction of the mean background from the right-hand curves yields intensity values identical with those for calcium alone, as in the left-hand curves. The relationship holds true with 5 p.p.m. of calcium in the presence of as much as 1,000 p.p.m. of sodium or potassium. The contribution of the background can be corrected for readily, and thus more accurate and precise flame spectrometry becomes possible.

Similar results were obtained when other permutations of these ions were studied. These results, under the conditions employed in our experiments, give no support to the hypothesis that 'interference' between calcium, sodium, potassium and magnesium in the source is caused by their energy relationships. Rather, they suggest that heterochromatic background radiation contributes to the observed analytical errors. The instrument here described should greatly facilitate the study of physiological relationships of these and other cations.

The design and construction of the instrument were supported by a grant from the C. F. Kettering Foundation, Dayton, Ohio, and the experimental work by a grant from the Office of Naval Research to Harvard University, Contract No. *N5 ori*—07660.

Infection of Chickens and Chick Embryos with the Viruses of Foot-and-mouth Disease and of Vesicular Stomatitis

IT has been generally believed that domestic or wild birds are resistant to infection with the virus of foot-and-mouth disease. Previous studies had been largely limited to experiments in mature birds which were observed mainly for epithelial lesions. Consideration was given, therefore, to the possibility that this virus might infect young chicks, with the involvement of cardiac and skeletal muscle as is observed in infection of the young of many other species.

In the first experiment (April 1953) chicks a few hours after hatching were inoculated intramuscularly with 10^6 ID_{50} of the 85th mouse passage of the cattle strain *M* 11 (Vallée *O* type). Pools of the inoculated muscles and of the hearts of chicks killed four days later each had a titre of 10^{-3} in mice one week old. The reacting mice were used as a source of virus for the inoculation of a further group of newly hatched chicks, and during a series of twelve alternate passages in chicks and mice carried out in this manner no difficulty was experienced in recovering the virus from the blood of the chicks over the period three to five days after inoculation.

Other chick tissues were tested at the same time, and consistently the highest titre ($> 10^{-5}$) was obtained with the tongue, on which macroscopic lesions were observed after the eighth alternate passage. Reverting to the original cattle strain, it was found that when 10^5 ID_{50} or more for mice were inoculated intramuscularly into newly hatched chicks, well-defined tongue lesions developed one to two days later. These lesions often involved the whole of the epithelium of the dorsum and appeared to be similar to the tongue lesions seen in other susceptible species. This was confirmed by histological examinations made by my colleague Dr. H. Platt. After direct inoculation of the tongue epithelium of older birds, local lesions developed and six serial passages of the cattle strain were made in this way in birds two to four months old.

Following intramuscular inoculation of large doses of another cattle strain (*VEN* 1 Vallée *O* type) and of three stock guinea pig strains of *O*, *A* and *C* types into newly hatched chicks, tongue lesions again developed and the guinea pig strains were passaged four to six times by intradermal inoculation of the tongue of older birds. With two of these strains, small areas of separation of the deeper epithelial layers developed near the points of pressure on the under surface of the feet of newly hatched chicks inoculated intramuscularly, and following direct inoculation of the area adjacent to the central pad of the foot slight local lesions were followed by severe secondary lesions on the tongue.

In chickens of all ages there was no severe systemic disturbance in the course of the infection. The epithelium from freshly developed tongue lesions usually had a titre of 10^{-6} or more in mice one week old. Even if the lesion was extensive, the affected epithelium was usually completely exfoliated in one or two days and the tongue left without blemish.

Material infecting chicks at the ninth of the alternate mouse – chick passages referred to above was inoculated intravenously into 14-day chick embryos and, after a single alternate passage in mice, serial passaging in 14-day chick embryos was continued by this route. In chick embryos of this age the myocardium appeared to be the main site of multiplication of the virus, and during the earlier passages the highest infectivity was reached after incubation of the inoculated eggs for five to six days at 35° C. At higher temperatures the susceptibility of the embryos to infection was reduced. After the eighth serial passage, infection was usually indicated by the death of the embryo three to six days after inoculation or by marked macroscopic lesions in the cardiac muscle of embryos killed during this period. The heart tissue and the pericardial effusion from such embryos usually had a titre of at least 10^{-6} in mice one week old, and 10^2 ID_{50} for mice was usually sufficient to infect 14-day embryos by the intravenous route, whereas embryos seven days old survived inoculation of 10^6 ID_{50} by the chorio-allantoic method and newly hatched chicks did not develop macroscopic heart or tongue lesions after the inoculation of larger doses by the intramuscular route. Chick embryo passaged strains with similar properties were later initiated with virus from the 24th and the 110th mouse passages of this cattle strain (*M* 11) without the intermediate use of chicks.

In attempts to initiate a chick embryo strain direct from the *M* 11 cattle strain using the intravenous route, recovery of the virus from embryos inoculated when eleven and fourteen days old was not achieved. The tongue tissue of embryos inoculated when seventeen to eighteen days old was found to be infective on the second and third day after inoculation, but passaging was not attempted. With the one other cattle strain (*VEN* 1) tested directly on chick embryos, severe macroscopic lesions in the myocardium were seen at the first passage five days after inoculation of 14-day embryos. Serial passaging in these embryos was continued without difficulty. Identical results were obtained with the same cattle strain after it had received twenty-nine culture passages in cattle tongue epithelium.

Other workers attempting to propagate the virus of foot-and-mouth disease in the embryonated hen egg have usually adopted the chorio-allantoic method of inoculation, and success has been achieved in only a few instances. The use of the intravenous route of inoculation, which brings the virus into immediate contact with the body tissues of the embryo, and the subsequent incubation at 35° C. for at least three days, may have been factors which contributed to success in the present experiments.

The virus of vesicular stomatitis can be propagated readily in chick embryos seven to ten days old. Only unsuccessful attempts to infect chickens have been recorded. However, in earlier work (unpublished observations, 1948) I had found that this virus could be passaged in chicks up to three weeks old by the intracerebral route. The tongue and feet were not then examined for lesions. A repetition of the methods used for infecting chickens with the virus of foot-and-mouth disease showed that adult and young birds were highly susceptible to infection with the virus of vesicular stomatitis when this was inoculated intradermally into the tongue. Virus strains of Indiana or New Jersey type previously passaged intradermally in guinea pigs or intracerebrally in mice were tested, and very severe local lesions developed within twenty-four hours. Guinea pigs or mice receiving the same inoculum by the most sensitive method in each case took 6–24 hr. longer to show signs of infection. The course of the infection was very similar to that seen in the case of foot-and-mouth disease. The vesicular epithelium of fresh tongue lesions was again highly infective. Two ducks also have been inoculated on the tongue with this virus, and local lesions developed in both.

In all these experiments the specificity of the infective agent has been checked.

Enhancement of Insulin Action by Pituitary Growth Hormone

The injection of purified preparations of pituitary growth hormone into normal[1], adrenalectomised[1] and eviscerated-hypophysectomized[2] rats results in a fall of blood sugar-level. The *in vitro* addition of pituitary growth hormone can, under certain conditions, increase the glucose uptake of the isolated diaphragm from normal[3] and hypophysectomized[3] rats, but cannot increase the glucose uptake of the isolated diaphragm from alloxan-diabetic rats[3]. This insulin-like action of growth hormone[3,4] may result from a direct action of the hormone, or from an enhancement by growth hormone of the usual action of insulin, or from an activation by growth hormone of insulin trapped in the diaphragm in an inactive form (Ottaway[3]). Dependence of the insulin-like action of growth hormone on the presence of insulin is strongly suggested by the failure of growth hormone to lower the blood sugar-level of alloxan-diabetic rats[1] or to increase *in vitro* the glucose uptake of the diaphragm from alloxan-diabetic rats unless the diabetic rat has received an injection of insulin before removal of the diaphragm[3].

The possible dependence of the insulin-like action of growth hormone on the presence of insulin has been investigated by studying the influence of low concentrations of insulin and growth hormone upon the glucose uptake of the isolated normal rat diaphragm, surviving *in vitro*. The growth hormone was prepared from ox pituitary glands by a modification of the method of Wilhelmi *et al.*[4]. Solutions of growth hormone of the required concentration were prepared by dissolving the hormone in the Gey's buffer[5] used for the incubation. Crystalline insulin (Boots, 23 units/mgm.) was dissolved in $N/300$ hydrochloric acid to make a stock solution containing 20 units/ml., and the solutions used for incubation were prepared by serial dilution with Gey's buffer. The experimental procedure was as follows.

The hemi-diaphragms of normal male albino Wistar rats of 100–150 gm. were used. The animals were fasted for 20 hr., killed by decapitation and the diaphragms rapidly removed, divided and washed for exactly five minutes at room temperature in Gey's buffer (containing glucose, concentration 2·5 mgm. per ml.) previously gassed with 93 per cent oxygen, 7 per cent carbon dioxide. The hemi-diaphragms were then lightly blotted and transferred to Warburg manometer cups containing 1 ml. of incubation fluid; the flasks were attached to manometers and incubated for three hours at 37° C. with a shake-rate of 100 cycles per min. The glucose concentration in all cases was 2·5 mgm./ml. and the gas phase during incubation was 93 per cent oxygen, 7 per cent carbon dioxide. At the end of incubation the hemi-diaphragms were blotted and weighed on a torsion balance and the residual glucose determined on 0·2-ml. samples of incubation fluid by the colorimetric method of Somogyi[6]. The glucose uptake was calculated as mgm. glucose disappearing from the medium per gm. of wet diaphragm per hr. of incubation.

Table 1. INFLUENCE OF DIFFERENT CONCENTRATIONS OF PITUITARY GROWTH HORMONE, ADDED *in vitro*, UPON THE GLUCOSE UPTAKE OF THE ISOLATED RAT DIAPHRAGM

Conc. of growth hormone added *in vitro* (μgm. per ml.)	Glucose utilization, mgm. glucose per gm. of wet diaphragm per hr. (Mean ± S.E. of mean)	No. of hemi-diaphragms	Comment
None	2·25 ± 0·14	8	No significant difference between any of these means
0·1	2·46 ± 0·24	8	
1·0	2·24 ± 0·21	8	
10·0	2·27 ± 0·22	8	
50·0	2·34 ± 0·25	8	
100·0	2·58 ± 0·24	8	

Table 2. INFLUENCE OF PITUITARY GROWTH HORMONE AND INSULIN, ADDED SEPARATELY AND TOGETHER, *in vitro*, UPON THE GLUCOSE UPTAKE OF THE ISOLATED RAT DIAPHRAGM

Incubation medium	Glucose utilization, mgm glucose per gm. of wet diaphragm per hr. (Mean ± S.E. of mean)	No. of hemi-diaphragms	Comment
Buffer	(*a*) 2·32 ± 0·08	23	*t* for *a* versus *b* is 11·6 $P < 0.001$
Buffer + growth hormone (conc. 0·1 μgm. per ml.)	2·30 ± 0·06	23	
Buffer + insulin (conc. 2 × 10^{-4} unit per ml.)	(*b*) 3·27 ± 0·10	23	*t* for *a* versus *c* is 12·7 $P < 0.001$
Buffer + insulin + growth hormone in above conc.	(*c*) 3·80 ± 0·08	23	*t* for *b* versus *c* is 4·27 $P < 0.001$

Under these experimental conditions, the *in vitro* addition to the fluid in which the isolated diaphragm was suspended of growth hormone alone had no influence upon the glucose uptake of the diaphragm at any concentration of growth hormone tested (Tables 1 and 2). The presence of low concentrations of both growth hormone and insulin resulted in significantly greater uptake of glucose by the diaphragm than was produced by insulin alone (Table 2).

These results confirm the earlier observation of Park *et al.*[3] that growth hormone itself has no influence upon the *in vitro* glucose uptake of normal rat diaphragm; it has not been possible to confirm, under these conditions, the observations of Ottaway[3] and of Bulbrook and Ottaway[7] that growth hormone can increase or decrease the *in vitro* glucose uptake of normal rat diaphragm, depending upon the concentration of growth hormone used. Nevertheless, these results show that the addition of growth hormone *in vitro* can increase the glucose uptake of normal rat diaphragm by enhancing the action of insulin also added *in vitro*.

Young[8] has recently commented that the enhanced rate of entry of glucose into the cell, which insulin can promote[9], may provide the additional energy needed for the cellular enlargement or mitosis which occurs under the influence of growth hormone. The results reported here suggest that one action of growth hormone may be to accentuate the action of insulin in promoting the entry of glucose into the cell.

I wish to thank the Medical Research Council for personal and expenses grants in aid of this investigation.

An Improved Resolution of Cytoplasmic Proteins of Rat Liver after *n*-Butanol Treatment

In an earlier communication[1], a technique was described for obtaining consistent separations of the cytoplasmic proteins of rat liver using electrophoresis on filter paper. A notable improvement in resolution has been observed following the treatment of the protein mixtures with *n*-butanol. The use of this reagent was suggested by the experiments of Morton[2] on the extraction of various enzymes from the particulate fractions of the cell structure.

The cytoplasm of rat liver (5 volumes), prepared as previously described[1], was shaken at room temperature with *n*-butanol (1 volume) and separated in a centrifuge. The lower aqueous layer was dialysed at 4° C. against distilled water to remove butanol and dried in the frozen state. The cytoplasmic proteins were obtained as a readily soluble powder. A 6–7 per cent solution of this powder subjected to electrophoretic analysis on filter paper as previously described[1] gives a characteristic reproducible pattern of seven bands; the correspondence between the patterns with and without the butanol treatment is illustrated in Fig. 1. Band No. 2 of the untreated sample has become resolved after butanol treatment into three distinct bands (2*a*, 2*b* and 2). Band No. 4 in both patterns corresponds to an esterase activity identified by the diacetyl-fluorescein reagent of Jermyn[3]. The esterase band is sometimes split into two close but distinct components.

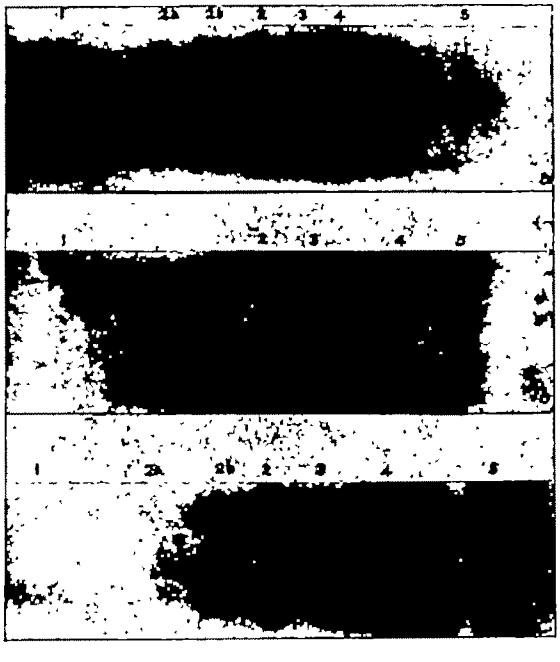

Fig. 1. Electrophoretic pattern of rat liver cytoplasm. *b*, Before, *a* and *c*, after butanol treatment. The numbering of the bands corresponds with those previously described (ref. 1)

Even when butanol is used, a borate buffer is required to obtain satisfactory resolution of the protein components.

Inhibition by Cystine of Lecithinase (α-Toxin) Production in *Clostridium welchii* (*perfringens*) BP6K

The highest yields of lecithinase per ml. of medium in cultures of *Clostridium welchii* were reported by Logan *et al.*[1]. In the course of investigations of factors present in this medium which increase toxin production, we have encountered specific instances of the inhibition of the production of lecithinase.

The medium was a pancreatic digest of beef heart prepared according to Logan[1], used at a level of 7·5 per cent of solids. Optimal iron and dextrin concentrations were determined for each fresh preparation of digest. Culture tubes containing 10 ml. of medium, final *p*H 7·5, were inoculated as described by Logan[1] and incubated for 16 hr. at 34° C. The tubes were then centrifuged and the supernatant tested for enzyme activity. The lecithinase activity was measured by the development of turbidity when the culture filtrate was incubated with lecitho-vitellin in the manner described by van Heyningen[2]. The final turbidities were read in a Coleman spectrophotometer at a wave-length of 590 mμ. From these turbidities the *LD*50 was obtained by comparison with a reference curve given by a stabilized control toxin solution which had been standardized in mice by intravenous injection. Such a standard curve was set up with each experiment.

The pancreatic digest of beef heart was fractionated by means of a 'Dowex 2' cation exchange resin; some of the fractions thus obtained, when added to the original medium, stimulated, while others inhibited, lecithinase production. The inhibition of lecithinase production appeared to be due in part to free amino-acids.

The effect of adding to the normal medium each of the common amino-acids (final concentration of $1 \cdot 5 \times 10^{-3}$ *M* L-amino-acid) was studied. Each of three amino-acids inhibited enzyme production. Thus cultures containing valine, cysteine or cystine had *LD*50/ml. of 375, 315 and < 10, respectively, as compared to a control culture which had 500 *LD*50/ml. Cystine suppressed lecithinase production whether added to the medium before autoclaving or as a Seitz-filtered solution at the time of inoculation. Cysteic acid had no effect on enzyme production when tested in a similar manner. The *in vitro* activity of the lecithinase is unaffected by cystine up to a concentration ten times that which produces almost complete inhibition of the production of the enzyme.

The effect of cystine would appear to be an inhibition of the production of the toxin rather than any modification of the protein formed (for example, toxoid). Three separate experimental approaches in addition to the measurement of lecithinase activity give results which support this view. A comparison of the lecithinase activity and of the hæmolytic, lethal and antitoxin-combining power of the control culture filtrates and filtrates of cultures grown with cystine was made, with the results summarized in Table 1. The control culture was a normal 7·5 per cent solids beef-heart medium, incubated at 34° C. for 16 hr. The cystine culture differed only in that L-cystine had been added to a final concentration of $1 \cdot 5 \times 10^{-3}$ *M*. Not all activities were measured on the same two culture filtrates but on similar filtrates prepared on different days. Lecithinase activity was measured by the lecithovitellin method of van Heyningen[2], α-toxin hæmolytic titre by the method of Roth and Pillemer[3], and the antitoxin-combining power by the method of Pillemer[4]. The lethal effect was measured by injecting intravenously into 18–20 gm. mice, 0·5 ml. of solution made by diluting culture filtrate with pancreatic digest of heart medium containing 3 per cent solids. The end-point was taken as that dilution which killed 50 per cent of the mice within 72 hr. By each method, cystine was shown to effect a marked decrease in activity.

Table 1. EFFECT OF CYSTINE ON VARIOUS ACTIVITIES ASSOCIATED WITH α-TOXIN

Activity measured	Control culture per ml. culture filtrate	Cystine culture per ml. culture filtrate
Lecithinase activity	500 *LD*50	<10 *LD*50
α-Toxin hæmolytic titre	2,500 units	500 units*
Lethal effect	400 *LD*50	<20 *LD*50
Antitoxin-combining power	10 *Lb*	<1 *Lb*

* These 500 units represent a maximum figure as some activity may have been due to φ-toxin, active under the conditions of the test.

This example of the specific effect of cystine on the production of lecithinase by an anaerobe demonstrates once again the difficulties of controlled production of α-toxin in a complex medium. Slight changes in the amino-acid composition of such a medium may have a marked effect on the synthesis of this protein.

A New Amino-acid in the Peel of Apple Fruits

SMALL quantities of an amino-acid which, from its position on two-dimensional paper chromatograms and other properties, does not appear to be an acid already reported in plant material, has been isolated, by use of a series of ion-exchange columns, as fine silky needles from the peel tissue of immature Worcester Pearmain apples. This acid is also certainly present in the peel of mature Edward VII apples and probably in the peel of other varieties, but it is absent from the sub-cortical tissue ('pulp') of all the varieties so far examined.

The position of this acid on chromatograms of the Worcester Pearmain peel is seen from Fig. 1, in which spot 1 represents hydroxyproline, spot 2 the new acid, spot 3 proline and spot 4 γ-amino-butyric acid. Sprayed with ninhydrin, the new acid gives a pinkish-yellow colour which shows an intense salmon-pink fluorescence in ultra-violet light. With isatin it gives an intense blue colour characteristic of pyrrolidine compounds[1]; piperidine compounds isomeric with methyl pyrrolidine give an intense and characteristic blue-green colour under similar conditions[2]. The new acid also gives the nitroprusside–acetaldehyde test for a secondary amine. None of these characteristic properties is affected by treatment with 6 *N* hydrochloric acid at 100° C. for 20 hr. Support for a pyrrolidine carboxylic acid structure comes from its being similar to proline in its anomalous behaviour on a series of phenol–methylene–sulphonic polystyrene cation and polystyrene anion resin columns[3]; it is, however, separable from proline on 'Zeokarb 215'.

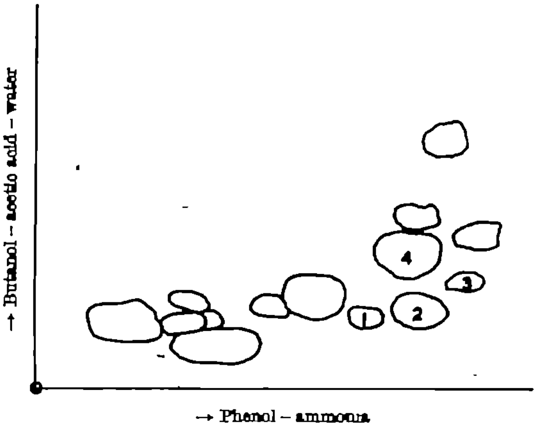

Fig. 1. Chromatogram of an extract of the peel of immature Worcester Pearmain apples with added hydroxyproline

It was at first thought that this compound might be identical with the compound isolated from the fruits and leaves of Granny Smith apples by Urbach and McKee[4], which these authors suggest is probably 4-methoxyproline. However, analysis of the 'acid 2' in Fig. 1 fails to reveal any methoxy group. Elementary analysis of the acid gives: C, 49·6; H, 7·7; N, 9·1 per cent. From the available evidence, including the position taken up by the acid on two-dimensional chromatograms, it is suggested that this new acid is a methyl-hydroxyl-proline, which would give an analysis of: C, 49·7; H, 7·6; N, 9·7 per cent. No evidence is available as to the position of the suggested methyl and hydroxyl groups.

When more of this compound becomes available, the infra-red spectrum of the acid will be examined for indications of hydroxyl and methyl groups.

Conversion of Schradan and Parathion by an Enzyme System of Rat Liver

Schradan (octamethyl pyrophosphoramide) and parathion (OO-diethyl O *p*-nitrophenyl phosphorothionate) are converted by insects or mammals into inhibitors of cholinesterase. In mammals the liver is responsible for the metabolism of both compounds[1] and the conversion appears to be an oxidative one.

Work in these laboratories has shown that the conversion of either compound can be obtained by rat liver suspensions shaken in air at 37° in the presence of nicotinamide, magnesium ions and diphosphopyridine nucleotide. Separation of a suspension of rat liver in saline or 0·25 *M* sucrose by differential centrifugation has resulted in the finding that liver microsomes, together with the soluble supernatant, can effect these conversions provided diphosphopyridine nucleotide (shown by a chromatographic technique to contain less than 5 per cent of the tri-nucleotide) is present. Conversion is not obtained with microsomes alone.

Brodie and Cooper[2] and Axelrod[3] have found that barbiturates and sympathomimetic amines are oxidized by liver microsomes and supernatant with the addition of triphosphopyridine nucleotide but not the di-nucleotide. These workers also made the surprising discovery that microsomes were only effective without supernatant if reduced triphosphopyridine nucleotide was added. With the conversion of schradan and parathion, the addition of a triphosphopyridine nucleotide preparation (15 per cent tri-nucleotide, 29 per cent di-nucleotide) to microsomes plus supernatant resulted in less conversion than an equivalent amount of diphosphopyridine nucleotide. Addition of glucose-6-phosphate to produce reduced triphosphopyridine nucleotide through glucose-6-phosphate dehydrogenase only increased the conversion of schradan. No satisfactory interpretation of these findings has so far been found.

Table 1. Conversion of Parathion and Schradan by a Rat-Liver Microsome Preparation.

Chilled rat-liver suspension was suspended (10 per cent w/v) in 0 15 *M* sodium chloride, 0 015 *M* magnesium sulphate and centrifuged for 10 min. at 8,500 *g* at room temperature. Nicotinamide was then added to give a final concentration of 0 008 *M* to the microsome and supernatant preparation. 0·4 mgm./ml. Diphosphopyridine nucleotide (70 per cent), 1 6 mgm./ml. triphosphopyridine nucleotide, 2 mgm./ml. glucose-6-phosphate, 1 mgm./ml. schradan and 200 μgm./ml. parathion were added as indicated. 10 (2 − $\log_{10}$ per cent activity) = units of inhibitor per 10 mgm. of protein

Addition	Schradan	Parathion
Diphosphopyridine nucleotide	73	500
Triphosphopyridine nucleotide	24	222
" and glucose-6-phosphate	80	153
No addition	10	7

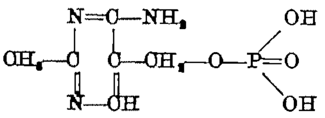
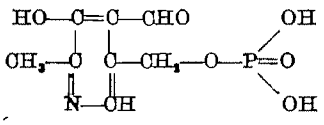
Competitive Inhibition of Pryidoxal Phosphate Action by Toxopyrimidine Phosphate in the Tyrosine Decarboxylase System

In the previous communication, it has been reported by K. Makino *et al.* that 'atoxopyrimidine', which protects against the onset of convulsions or death of the mouse and rat caused by the injection of the pyrimidine moiety of thiamine(2-methyl-6-amino-5-hydroxymethylpyrimidine, which they called 'toxopyrimidine'), is contained in rice bran. Moreover, they confirmed that the vitamin B_6-complex has strong atoxopyrimidine action[1,2], indicating a typical 'biological antagonist' owing to the similarity of its structure to that of toxopyrimidine.

We have now attempted to find whether an analogous relation exists between toxopyrimidine phosphate (I) and pyridoxal phosphate (II) in an enzymic system.



(I)



(II)

We synthesized the phosphoric ester of toxopyrimidine by treating the latter with phosphorous oxychloride and investigated the inhibitory action of this synthetic compound on the bacterial tyrosine decarboxylase which is one of the vitamin B_6-dependent enzymes formed by *Streptococcus faecalis* R.; the results obtained agreed very well with our assumption.

The synthesis of toxopyrimidine phosphate was carried out as follows: toxopyrimidine was dissolved into 1 *N* hydrochloric acid and water, cooled, and phosphorous oxychloride was added with stirring at such a rate that the temperature did not exceed 50° C. After hydrogen chloride had been removed *in vacuo* as much as possible, the reaction mixture was cooled and neutralized to *p*H 5 $\sim$ 6 by adding a suspension of calcium carbonate in water, and again chilled, and filtered. The filtrate was diluted with three times its volume of alcohol with chilling, and the precipitate thus formed was gathered by centrifugation, and washed with alcohol and ether. This crude compound was purified by fractional precipitation with alcohol. The yield was 10 per cent of the theoretical. R_F values of this compound by paper chromatography using Tōyō Roshi filter paper No. 50 were 0·45 or 0·31 with a mixture of acetone with 85 per cent formic acid in the ratio 60/40 or 40/20, 0·45 with a mixture of acetone with 50 per cent acetic acid in the ratio 50/50 and 0·25 with a mixture consisting of lutidine, water, alcohol and diethylamine in the ratio 55/25/20/1 as developers. The ultra-violet absorption spectrum of the calcium salt of this synthetic compound showed at *p*H 1·2, λ_{max} 245·5 mμ, and at *p*H 12, $\lambda_{max\ 1}$ 271·5 mμ and $\lambda_{max.2}$ 233 mμ.

In the preliminary experiment, we found that the activity of holotyrosinedecarboxylase which was obtained by autolysing the dried acetone extract of *St. faecalis* R. in 0·02 *M* phosphate buffer (*p*H 5·5), which was grown on a synthetic medium containing yeast extract, was inhibited to the extent of 99, 92, 52, 17 and 14 per cent by the synthetic phosphate (I) in concentrations of 3×10^{-6}, 3×10^{-7}, $7·5 \times 10^{-8}$, 3×10^{-8} and 3×10^{-9} *M*, respectively.

St. faecalis R. was also grown on a vitamin B_6-deficient synthetic medium; from this a cell-free preparation of the tyrosine apodecarboxylase was prepared according to Epps's method[3]. Assay of the tyrosine decarboxylase was carried out as follows: 0·02 *M* tyrosine, 0·666 *M* acetate buffer (*p*H 5·5), pyridoxal phosphate ($3·2 \times 10^{-7} \sim 3·2 \times 10^{-10}$ *M*), inhibitors ($1 \times 10^{-6} \sim 1 \times 10^{-10}$ *M*), purified apoenzyme and water to make a total volume of 2·0 ml.; temperature 30° C.

Tyrosine apodecarboxylase prepared by us was activated so sensitively that $\frac{1}{2}$ $V_{max.}$ was attained by addition of $1·6 \times 10^{-8}$ *M* pyridoxal phosphate, a value which agreed well with that reported by O'Kane and Gunsalus ($1·5 \times 10^{-8}$ *M*)[4].

The effects of toxopyrimidine and its phosphoric ester on the activity of the purified tyrosine decarboxylase were as follows: (1) toxopyrimidine itself had no inhibitory action at concentrations between 1×10^{-6} *M* and 1×10^{-10} *M*, regardless of the concentration of pyridoxal phosphate; (2) toxopyrimidine phosphate at a concentration of 1×10^{-7} *M* inhibited 99 ∼ 100 per cent of its activity, and at concentrations of 5×10^{-8}, 1×10^{-8}, 1×10^{-9} and 1×10^{-10} *M* showed inhibition of 60, 20, 16 and 0 per cent, respectively.

We are indebted to Dr. T. Matsukawa for giving us a sample of toxopyrimidine, and to Dr. Y. Sakurai for supplying a sample of pyridoxal phosphate. This work was aided by the Scientific Research Fund of the Ministry of Education of Japan.

Isolation of Lignin from Finely Divided Wood with Neutral Solvents

IN 1939, Brauns[1] found that a few per cent of the total amount of lignin is present in the extractives obtained from black spruce with ethanol. It is now well known that greater proportions of lignin cannot be extracted from wood unless the solvent contains an acid reagent or rather drastic conditions are used, resulting in more or less severe alteration of the lignin. This fact is usually explained in two ways: (1) chemical bonds exist between lignin and the carbohydrates; (2) lignin has a very high molecular weight, and may form a three-dimensional network. A third possibility, that weak forces like hydrogen bonding and physical phenomena may be involved in the retention of lignin, has not been given much consideration, though such forces would render the dissolution of cellulose in water impossible.

I have re-examined the problem of extracting lignin with solvents with the last-mentioned possibility in mind, and with due consideration to the mechanism of grinding in a ball mill. The difference in dissolving power of various lignin solvents has also been considered. I have found it possible to extract about two-thirds of the lignin from spruce at room temperature after grinding wood sawdust in a vibrational ball mill[2]. To aid the grinding, the wood was dispersed in a liquid. It was found, however, that the liquid must not swell wood more than a few per cent, otherwise the wood becomes difficult to handle and little or no lignin is released in the extraction step. It is equally important that the amount of wood in the mill should be small enough to allow the 'equilibrium curve', which characterizes the milling performance[3], to reach its peak at a sufficiently small particle-size. The ideal milling liquid is hard to select; toluene has been used in most experiments.

The choice of lignin solvent for the extraction of milled wood is not critical, though the extraction is quicker and more complete with solvents which stand moderate dilution with water without the lignin being precipitated, for example, 'Methyl cellosolve' (ethylene glycol monomethyl ether). Depending on the grinding conditions, more or less of the lignin is extracted rapidly; but for maximum yield the extraction must go on for months. In a blank with the original sawdust, from which the 'Brauns's native lignin' had been removed by pre-extraction with ethanol and 'Methyl cellosolve', no extraction occurred during eighteen months. Solvents like ethanol, acetic acid and dioxane require a small amount of water in order to dissolve lignin, but substantial water content will reduce the dissolving power considerably. Mixtures of ethanol and chloroform or ethanol and 1,2-dichloroethane are powerful solvents but very sensitive to water. It is believed that in dissolving lignin the many hydroxyl groups of the wood carbohydrates have an influence similar to water on the solvents, which makes 'Methyl cellosolve' a superior extraction medium.

As already indicated, the grinding conditions are most important in obtaining high lignin yields. It remains to be determined if all the lignin can be removed by this technique. Definite conclusions as to the state of lignin in wood cannot be made yet, but there seem to be indications that few, if any, bonds exist between part of the lignin and the carbohydrates. Moreover, the diffusion of part of the lignin in wood is apparently extremely slow. It should be added that the average temperature during the grinding was only slightly greater than room temperature.

This new material (milled wood lignin) has been obtained as a faintly cream-coloured powder from spruce, pine, birch, aspen, western hemlock and black spruce, and an evaluation of its authenticity as a chemically unchanged lignin is under investigation. It seems to differ in several respects from Brauns's native lignin. Brauns's native lignin and milled wood lignin obtained from the same spruce

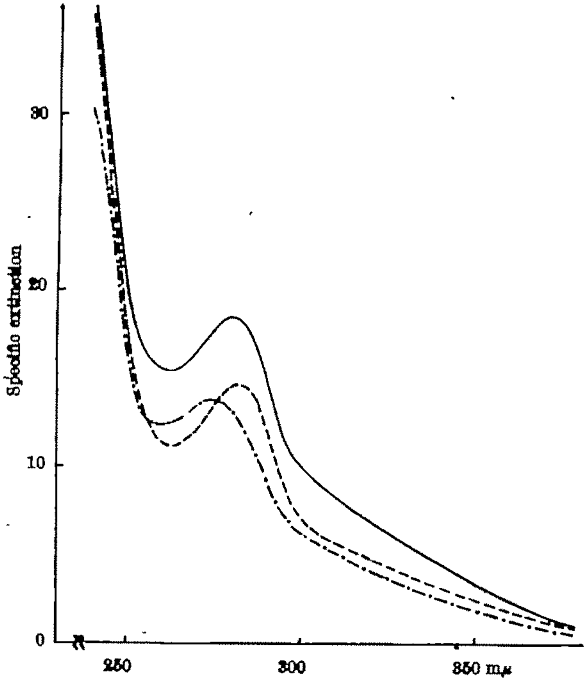

Fig. 1. Specific extinction versus wave-length: ———, milled wood lignin from spruce; —·—·—, milled wood lignin from aspen; — — —, low-sulphonated lignosulphonic acid. Solvent: 'Methyl cellosolve'

log had methoxyl contents of 14·8 and 15·5 per cent respectively, after thorough purification; in the case of the latter, there are indications of a slight variation of MeO with the yield of lignin, but further investigations are required to elucidate this point. Milled wood lignin from spruce dissolves considerably more slowly than Brauns's native lignin in solvents, and the solutions of the former have a lighter colour than those of the latter. The content of phenolic hydroxyl groups in the milled wood lignin from spruce has been estimated according to Aulin-Erdtman[4] and Adler and Hernestam[5] and was found to be lower than in Brauns's native lignin. The ultra-violet absorption spectra of milled wood lignin from spruce and aspen are shown in Fig. 1 together with the spectrum of a low-sulphonated lignosulphonic acid from spruce.

Details on the characterization of milled wood lignin as well as its reactions will be given in forthcoming papers.

Since the inception of this work, ultrasonics and a colloid mill have been tried to release the lignin with no success. This may be due partly to the circumstance that the treatments were carried out with the wood dispersed in lignin solvents causing the blocking effect of swelling as stated above.

This work has been supported by a grant from Statens Tekniska Forskningsråd, Sweden.

Structure of Cotton Alpha-Cellulose

THE structure of cotton α-cellulose has been developed on the assumption that its building unit is glucose only. It is, of course, believed that raw cotton contains small amounts of pentoses which are removed by prolonged boiling in alkali and subsequent treatment of the product with 17·5 per cent sodium hydroxide during the preparation of purified α-cellulose. Chromatographic analysis has shown[1] that raw cotton contains glucose, xylose, arabinose and a trace of rhamnose. Adams and Bishop[2] reported that cotton α-cellulose does not contain any pentose. But our findings[1,3] that a part of the pentoses is very strongly associated by chemical bonds with jute α-cellulose, which was also later confirmed by Adams and Bishop[3,4], suggested reinvestigation of the association of these pentoses with purified cotton α-cellulose.

For this purpose various samples of raw cotton from different sources have been examined and precautions taken in the preparation of purified cotton α-cellulose. Wax, etc., was removed from raw cotton by prolonged alternate extractions with alcohol and ether followed by washing with water. The air-dried product was then treated with 1 per cent boiling sodium hydroxide for a period of 10 hr. as outlined by Corey and Gray[5]. α-Cellulose was then prepared by treating this purified cotton with the usual 17·5 per cent sodium hydroxide.

By hydrolysing the α-cellulose by the formic acid method[6] (85 per cent, 12 min. at the boil) and analysing chromatographically the hydrolysate in different solvents (for example, moist *n*-butanol, moist phenol and *n*-butanol/acetic acid/water mixture), the presence of glucose, xylose and arabinose was readily detected. A typical chromatogram (Fig. 1) is reproduced. This observation, obtained by the formic acid method, has been confirmed recently by G. A. Adams of the National Research Council, Canada (private communication), who also states that these findings with cotton α-cellulose are at variance with those of Adams and Bishop[2] when they used a different technique and did not find any trace of pentose sugars.

Cotton α-cellulose was also hydrolysed by the 72 per cent sulphuric acid method and the hydrolysate examined chromatographically, but the identification of pentoses was found to be very difficult. If, however, before spraying the chromatogram with aniline oxalate reagent the lower portion of the spot corresponding to glucose is cut off, extracted with water, concentrated and chromatographed again, xylose and arabinose are readily detected. Further proof of the presence of pentoses in cotton α-cellulose was obtained by separating these pentoses from glucose present in the hydrolysate (72 per cent sulphuric acid) of Egyptian cotton α-cellulose (2 gm.) through a cellulose column with an alcohol/benzene (35 : 65) mixture as developed in this laboratory[7], followed by chemical analysis. The above results therefore show that xylose and arabinose are present not only in α-cellulose derived from jute or allied materials but also in that prepared from purified cotton. Estimation of the amounts of these pentoses associated with this α-cellulose is in progress. The main difficulty is to assess the amount of pentoses that decomposes under the exact condition of complete hydrolysis of α-cellulose. Nevertheless, from the nature of the chromatogram, it appears that the total amount is likely to be appreciable. On

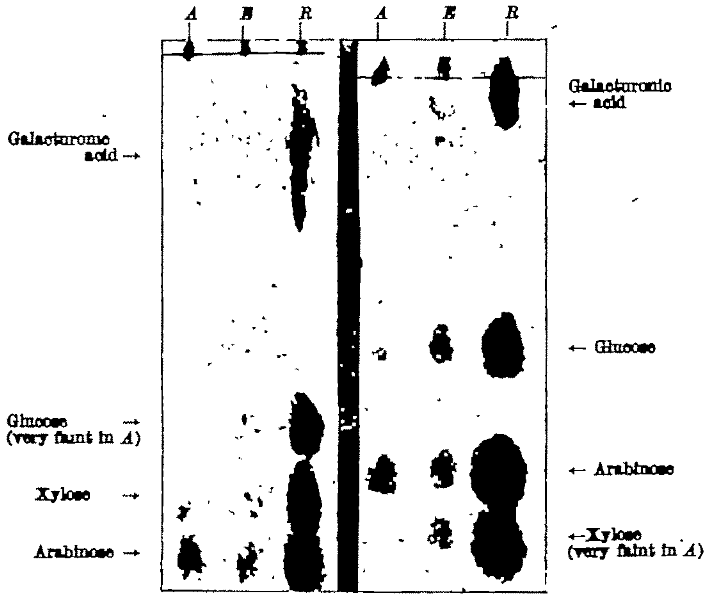

Fig. 1. *A*, American cotton α-cellulose; *E*, Egyptian cotton α-cellulose; *R*, reference sugars.

Left: Chromatogram in moist phenol for 48 hr. in Whatman filter paper No. 1.

Right: Chromatogram in moist *n*-butanol for 96 hr. in Whatman filter paper No. 1

these grounds we feel that the above observations may have far-reaching implications for the accepted structure of cotton α-cellulose. The possibility of mixed crystals with these pentoses and glucose cannot be ruled out, and as already noted[8], it remains to be seen if the new spacing observed recently by Sen and Roy[9] even in cotton is due to such mixed crystals.

Thanks are due to the Indian Central Cotton Committee and Ahmedabad Textile Industries Research Association for the samples of raw cotton.

Localization of Embryonic Antigens by Antisera labelled with Fluorescent Dyes

Antibodies labelled with fluorescent dyes have been used for histochemical localization of antigens in tissue sections by Coons and Kaplan[1], Marshall[2] and Hill and Cruickshank[3]. It would seem that this method might be applied to locate tissue antigens during the course of development.

Since the changes in distribution of antigens relative to one another at different stages of development are of interest from the point of view of differentiation, a modification of the method, which enables one to study several antigens simultaneously, has been employed. The use of a mixture of several antisera of different specificities, each coupled to a different dye, makes this possible. It has a further advantage in practice. The antibodies appear to compete to some extent, which has the effect of eliminating some of the minor cross-reactions. Thus a given antiserum will give more restricted localization in combination with another antiserum than by itself.

The colours chosen were green, yellow and red fluorescence; these were found to be readily distinguished from one another.

The green was due to fluorescein isocyanate, which Dr. R. Smith, of King's College, London, kindly coupled on to a number of samples of antisera. The yellow was 1-dimethyl-amino-5-sulphonyl-chloride-naphthalene, a sample of which he also provided. The red was nuclear fast red (benzaldehyde-6-nitro-2-sodium-diazotate). All uncombined dye was removed by dialysis. Samples of each antiserum were coupled to each of the three dyes, the specificity and localization remaining the same whatever the colour. The antisera thus treated were against lens and muscle respectively of the mouse, *Mus musculus*.

The eye of the week-old mouse (which has also been made the subject of a quantitative study by means of radioactive antisera[4]) was treated with a mixture of muscle and lens antisera after freeze-drying and sectioning in paraffin. Where, for example, the lens serum was dyed red and the muscle green, the following localizations were observed: lens bright red, ciliary process and retina pale pink, epithelium of cornea doubtfully pale pink, extrinsic muscles and suspensory ligament green, choroid pale green. The cross-reactions indicated by the paler colourings may be due either to small quantities of the same or to a similar antigen. Thus the ciliary process, which in Amphibia can regenerate the lens, may actually contain small quantities of lens crystallins or scleroproteins. The choroid and suspensory ligament must contain antigens similar to or identical with some of those in whole muscle.

In the early stages of the embryo mouse, the lens antisera give a diffuse reaction with the brain and a somewhat stronger one with the eye cup and lens vesicle. The highest fluorescence surrounds the cavity of the lens vesicle. There is a cross-reaction of the lens antiserum with the epidermis, which is strongest in the adult.

Thus the use of labelled antibodies may make possible a simple and direct test of insoluble antigens hitherto tested only by indirect methods which may be subject to interfering factors.

A full report will be published elsewhere.

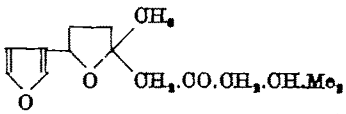
Increase of Respiratory-rate in Sweet Potato Tissue infected with Black-Rot

An increase in respiratory-rate is commonly observed in the tissues of higher plants when infected by pathogens. We have found the same phenomenon to accompany black rot in the sweet potato caused by *Ceratostomella fimbriata* infection, and the simultaneous activation of cytochrome oxidase, polyphenol oxidase and peroxidase in the tissues.

P. J. Allen[1] believed from his observation of increase of inorganic phosphate and inhibition of Pasteur effect in wheat infected by powdery mildew that the respiratory increase could be explained by the mildew toxins acting as uncouplers and accelerating the release of inorganic phosphate and regeneration of adenosine diphosphate; thus a given level of phosphate acceptors would lead to more rapid oxidation. We, on the other hand, took the view that something metabolized in the infected sweet potato might act as an uncoupler and permit the respiratory increase.

Several substances have been found as abnormal metabolites in black-rot of sweet potato. Ipomeamarone,



(130°/3 mm. mercury), was found by M. Hiura[2] in infected tissue, and its structure determined by T. Kubota *et al.*[3]. In sound tissue next to the infected part, polyphenols such as chlorogenic acid[4] (isolated by G. Rudkin *et al.* from sound tissue), isochlorogenic acid and a new isomer which we call pseudochlorogenic acid, and also coumarins such as umbelliferon and scopoletin have been isolated by us. Among these, ipomeamarone was known from our experiments to accelerate the respiration of sweet potato slices by *c.* 30 – 50 per cent in a dilution of 1 : 4,000, while 2,4-dinitrophenol ($2{\cdot}5 \times 10^{-4}$ *M*) showed *c.* 100 per cent increase under the same condition. Further, ipomeamarone in a dilution of 1 : 10,000 gave a slight increase of oxygen uptake with white potato tubers.

We have now examined these effects on the oxidative phosphorylation system of mitochondria-like particles in mung bean and sweet potato (using Maruo's method[5] and Bonner's method[6]). We find that ipomeamarone (1 : 4,000) distinctly depressed the coupled phosphorylation, as did also 2,4-dinitrophenol, though there was no apparent influence on oxygen uptake. Coumarin substances did not show any similar action. Chlorogenic acid inhibited to some extent the oxidative phosphorylation of sweet potato tissue particles only; this, we supposed, was because of the inhibitory effect of chlorogenic acid oxidative products which were produced by polyphenol oxidase in sweet potato tissue. A fraction (180°/3 mm. mercury) in the infected tissues, also, increased the respiration in sweet potato slices, and depressed the oxidative phosphorylation of the particles.

Ipomeamarone, in addition to being a factor concerned in the abnormal increase of respiration in sweet potato, may be considered to be a protector against the penetrating fungus: ipomeamarone was found to inhibit the spore germination[2], growth[7] and oxidative phosphorylation of *Ceratostomella fimbriata*, and depress its respiration in a higher concentration.

Table 1. Effect of Substances from Black-rot Tissue of Sweet Potato on Oxidative Phosphorylation of the Mitochondria-like Particles in Mung Bean and Sweet Potato

The control contained 20 μ*M* of phosphate buffer (pH 7·0), 20 μ*M* of citrate, 100 μ*M* of glucose, 3 μ*M* of adenosine triphosphate, 20 μ*M* of magnesium chloride, 20 μ*M* of sodium fluoride, 20 μ*M* of versene, 3 mgm of hexokinase, and 1·0 c.c. of enzyme solution (mitochondria-like particles prepared by Millerd's procedure as improved by Akazawa) in a total volume of 2·5 c.c. 60 min. incubation at 30° in Warburg vessels

	180°/3 mm. mercury,	500 γ	2·25	1·29	0·57
	Chlorogenic acid,	4·2 μ*M*	4·27*	1·78	0·44
,,	Control		1·40	2·10	1·41
	Umbelliferon,	4·2 μ*M*	1·54	2·10	1·36
	Scopoletin,	4·2 μ*M*	1·58	2·10	1·33

* Oxygen uptake here is much more than the control, due to the oxidation of chlorogenic acid by polyphenol oxidase in the particles.

Higher activity of adenosine triphosphatase in black-rot tissue of sweet potato, compared with that in sound sweet potato tissue, seems to be one of the factors for the occurrence of oxidation uncoupled to phosphorylation.

We thank Prof. Yusuke Sumiki, Tokyo University, and Prof. Saburo Funahashi, Nagoya University, for advice and encouragement, and also Dr. P. J. Allen, University of Wisconsin, for valuable suggestions.

Micro-fungal Population of Acid Sandy Podsols

We would like to direct attention to the remarkable similarity between the composition of the micro-fungal population of some acid sandy podsol soils in England, as recorded by Jeffreys, Brian, Hemming and Lowe[1], and that of some acid podsol soils in Victoria, Australia[2]. This similarity is associated with the presence in the *B*-horizon of what is described as an iron-pan in the English soils.

The *B*-horizon of the Australian podsol studied by us has been referred to as an iron-pan. However, analysis has shown that only a trace of iron is usually present, the characteristic dark colour being due to the abundant organic matter. In both soils the C-horizon was sand.

In each country this type of soil is characterized by the marked dominance of *Mortierella ramanniana* (Moll) Linnemann[3] (syn. *Mucor ramannianus* Moll). Jeffreys *et al.* state that this form was "usually particularly abundant in the pan layer. This may have been purely fortuitous but is worthy of record". Our results show that the distribution of this fungus is not fortuitous, for it formed 98 per cent of the population of the B-horizon in one experiment, and 86 per cent when all the samplings were considered. In those English soils in which *M. ramanniana* was absent, the pan was not a feature of the profile. We have some evidence that this is true for Australian soils also. It seems, on the evidence, that it is the characteristic micro-fungus of acid sandy podsols irrespective of geographical location, and that its dominance is indicative of such soil types.

The species list given in the profile tables for the English soil is equally descriptive of those compiled for the Australian profiles. The general micro-fungal population is practically identical, in contrast to the different floristic population of the heathlands in the two countries.

Of the Penicillia isolated from the Australian podsol twenty-six were tested for antibiotic activity against bacteria. Of these, thirteen gave a positive result with *S. aureus*, and only one, *P. rubrum* Stoll, was inhibitory to both *S. aureus* and *B. coli*.

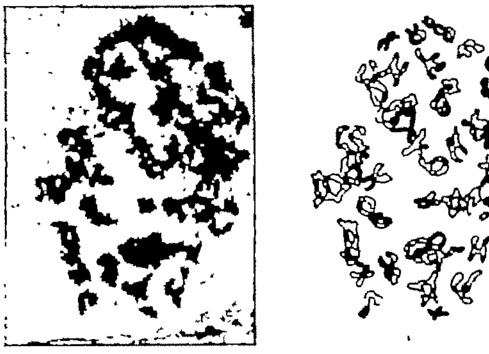
Allopolyploidy in the Melaniid Snails

IN a recent communication[1], I recorded the occurrence of apomictic parthenogenesis combined with polyploidy in a few species of *Melanoides*. One of these species, *Melanoides tuberculatus*, includes a diploid race with $2n = 32$ chromosomes and a polyploid race with 90–94 chromosomes, which thus appears to be more or less at the hexaploid level when compared to the former. Both these races are parthenogenetic, but in the latter there occur exceptional males which are sterile, constituting about 3 per cent of the population. The males show evidence of structural and numerical hybridity in the occurrence of bridge and fragment in the meiotic divisions and in the presence of non-pairing univalents with irregular distribution in the first meiotic metaphase and anaphase.

The present communication records the analysis of the chromosome combinations in the hybrid. Figs. 1 and 2 show the diakinetic stage from an aceto-carmine squash of the testis of the rare males of the polyploid race of *Melanoides tuberculatus*. Fig. 2 shows twenty univalents represented in black and thirty-five bivalents and a quadrivalent (right of centre) in dotted outline. From examination of diakinetic, first metaphase and first anaphase stages, it is found that a maximum of six quadrivalents may be present, bivalents may vary from thirty to thirty-eight and the number of univalents show less variation, usually from fifteen to twenty. During the first meiotic division the univalents pass undivided to the poles in a random fashion in advance of the separating bivalents, and the secondary spermatocytes possess an unequal number of chromosomes. The complete absence of trivalents and higher multivalents other than quadrivalents is a noteworthy feature.



(1) (2)

Diakinetic stage, acetocarmine preparation. (1) Photomicrograph; (2) camera lucida drawing. × 900

It is evident from the chromosome behaviour that the polyploidy involved is certainly not regular autopolyploidy with homologous sets of chromosomes. The presence of fifteen to twenty non-pairing univalents in all the stages analysed indicates hybridity involving more than one genome. The evidence of structural hybridity has been already mentioned. The polyploidy is therefore allopolyploidy. There is no sure way of distinguishing an allopolyploid, unless its origin is known or unless it is a rather extreme or typical example of one of the known types. However, in the present instance the presence of dissimilar genomes seems certain. The fact that up to six quadrivalents occur (though the number is small compared to the total number of chromosomes of this polyploid) indicates that at least certain chromosomes are represented four times. The polyploid is therefore probably autotetraploid with respect to one genome, but since a different genome is also present as stated earlier, it is allopolyploid. The polyploid race of *Melanoides tuberculatus* is an allopolyploid somewhat similar to what has been classified as autoallopolyploid by Kostoff[2] and what Darlington[3] refers to as an allopolyploid with non-reduction in the female parent. A cross between an apomictic autotetraploid and another diploid bisexual species might result in a hybrid of the type discussed here. However, this conjecture cannot be verified experimentally, since neither an autotetraploid nor a diploid bisexual species appears to be available.

Very similar features have been observed also in the meiotic stages of the rare males of *Melanoides lineatus*. Suomalainen[4] inferred allopolyploidy from the gonomery at the maturation metaphase. Except for this example, polyploidy recorded in animals so far is autopolyploidy. In view of the rarity of natural hybrids among animals, the allopolyploidy in *Melanoides* is of great interest.

I wish to thank Prof. R. V. Seshaiya for suggesting the problem and guidance, and Prof. A. D. Peacock for reading the manuscript.

Constitution of Cynarine, the Active Principle of the Artichoke

It has been known for some time that the artichoke (*Cynara scolymus*) contains some hitherto unidentified substances which stimulate biliary secretion and cholesterinic metabolism[1]. The extraction of these substances can be carried out by infusion or decoction. We have been able to isolate from cauline leaves of *Cynara scolymus* a crystalline substance which we have also found in *Cynara cardunculus*. Because of its physiological activity, we have used the word 'cynarine', which has been generally used for the chemical principle of the artichoke with the same activity[2].

We have isolated this compound by treating a decoction of the fresh leaves with lead acetate. The precipitate is extracted with dilute acetic acid and the lead is removed with sulphuric acid and hydrogen sulphide. Crystallization of the cynarine is obtained after concentration and standing. The yield is 0·1–0·2 p.p.m. of the leaves. It gives flat needles or colourless small plates of melting point 227–228° (dec.). It is slightly soluble in cool or warm water, more soluble in alcohol and acetic acid.

The substance has a left-handed rotatory power: $[\alpha]^{20}_{D}$, $= -59$ (methanol, $c = 4$). It is a weak acid, giving deep yellow alkaline solutions slightly stable in air. It gives a green colour with ferric chloride; it can be easily oxidized and gives a yellow precipitate with lead acetate and with barium hydroxide.

After drying in air to constant weight the percentage composition is $C_{25}H_{24}O_{12}.H_2O$. It gives a hexa-acetyl derivative (m.p. 168–172°) and a tetrahydro derivative (m.p. 134–140°).

Protocatechuic acid (3,4-dihydroxybenzoic acid) can be obtained by fusion with alkali. Its saponification by diluted alkalis produces quinic acid (1,3,4,5-tetrahydroxycyclohexane carboxylic acid) and two molecules of caffeic acid (3,4-dihydroxycinnamic acid); saponification of the tetrahydroxy derivative produces quinic acid and dihydrocaffeic acid.

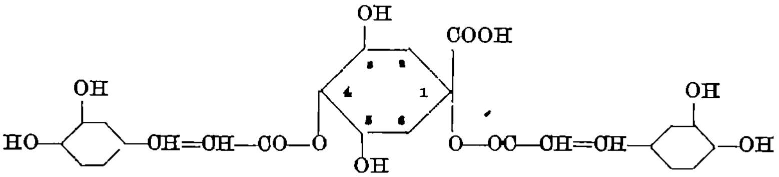
Methylation of cynarine with methyl sulphate and potassium carbonate in acetone gives pentamethyl-cynarine (m.p. 160–161°). Alkaline saponification of this compound gives methyl alcohol, quinic acid and two molecules of 3,4-dimethoxycinnamic acid; permanganic oxidation gives veratric acid.

Such data are sufficient for establishing that cynarine is a three-depside which occurs by esterification of two molecules of caffeic acid and one of quinic acid.

Because in the synthesis of cynarine the caffeic groups are introduced on the γ-lactone of quinic acid (quinide) we can exclude, among six isomeric esters, those blocking —OH of quinic acid in position 3. The pentamethyl-cynarine is stable to periodic acid and for this reason we can exclude the isomer 1–5 also. Hence, we can reduce the number of possible isomers to two (1–4 and 4–5).

The complete methylation of pentamethyl-cynarine by methyl iodide and silver oxide gives a substance that can be saponified. We obtain 3,4-dimethoxycinnamic acid and a dimethylether of quinic acid (m.p. 136–138°). Because of the resistance of this last compound to oxidation with periodic acid, it must be the 3,5-dimethoxy 1,4-dihydroxycyclohexane carboxylic acid.

Therefore the chemical formula of cynarine is:



More details of this work will be published elsewhere, with an account of the synthesis of cynarine.

A New Paper Column for Preparative Chromatography

SEVERAL types of paper columns have been described for separating closely related substances on a preparative scale; but with these methods it has proved difficult to get the same degree of separation as is achieved by simple paper-strip experiments[1]. This disadvantage is overcome by the present method, the principles of which have been reported in a previous communication[2]. The technique has now been improved and simplified.

The column (manufactured by Grycksbo Pappersbruk, Sweden, and sold by LKB-Produkter Fabriksaktiebolag, Stockholm) consists of a roll of filter paper (*A*), closely packed around a central core (*B*) of inert material and placed in a polythene tube (*C*), closed at each end (Fig. 1). Close packing is a prerequisite for sharp fronts, because otherwise the solvent velocity varies through the cross-section of the column, reaching a maximum at the outer and inner column surfaces. Before using the column, solvent must be absorbed by the paper roll, which then swells and, being confined by the walls of the column, is subjected to great pressure. This condition ensures a constant flow velocity throughout the cross-section, thus achieving straight fronts and sharp separations. After the paper roll has been wetted by solvent through the lower cover, tube *C* is dipped into the

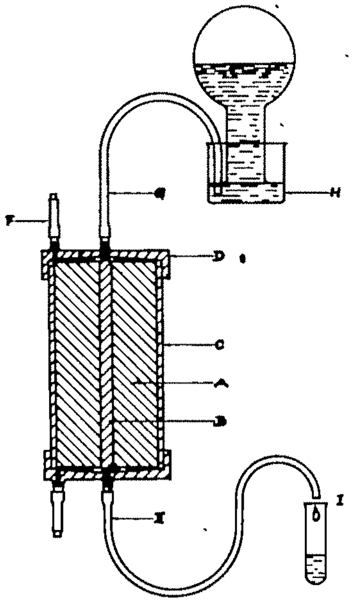

Fig. 1. Diagram of the chromatographic column

beaker (*H*) containing solvent. By applying suction to tube *F*, tube *G* and the upper space between the inner wall of the cover and the upper end of the roll are filled with solvent. Tube *F* is then closed and the solvent flows through the column. Equilibrium is established in a few hours, after which tube *G* is introduced into the container holding the solution, and the required volume of solution drawn into the column. Tube *G* is again transferred to the beaker (*H*), and separation ensues. Tube *E* is coupled to a fraction collector. The flow velocity is controlled by the height of the beaker (*H*) relative to the outlet (*I*). The effectiveness of separation is a function of flow velocity.

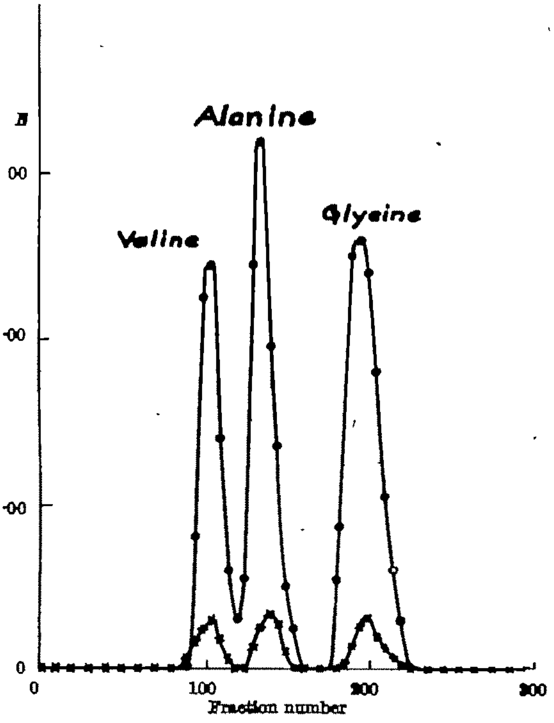

Fig. 2. Separations of glycine, alanine and valine

Fig. 2 shows the results of two experiments. In one experiment (crosses), 25 ml. of a solution containing 25 mgm. glycine, 25 mgm. alanine and 25 mgm. valine in 70 per cent ethanol were used. In the other experiment (filled circles) 250 mgm. glycine, 250 mgm. alanine and 250 mgm. valine dissolved in 100 ml. of 70 per cent ethanol were used. The elution was carried out with 3·8 l. of 70 per cent ethanol. The dimensions of column used were 10 cm. × 25 cm. The volume of each fraction was 15 ml. The elution process was continued for 48 hr. Every fifth fraction was analysed for amino-acids with the ninhydrin method according to Moore and Stein[3]. Fig. 2 shows that the amino-acids are separated sharply into three peaks.

The column has also been used for salting out chromatography according to Hagdahl and Tiselius[4] with excellent results. Glycyl-l-tryptophan, glycyl-l-tyrosine and glycyl-glycine were separated in 1 *M* disodium hydrogen phosphate + 2 *M* sodium dihydrogen phosphate on a 5-cm. column, 10 cm. in diameter. Metal ions have also been separated using this type of column.

Repeated use has been made of the column, and different columns give consistent and reproducible results. The amount of substances separated by this method is only limited by the dimensions of the column.

Improvements in Vapour-phase Chromatography at Relatively High Temperatures

FURTHER experience of the application of the vapour-phase chromatographic method to fatty-acid esters and fatty alcohols[1] has led us to adopt certain improvements which are of general interest. The separation of fatty-acid esters was found to be considerably influenced by the quality of the silicone grease used in the chromatograph column, and, in fact, some batches of silicone grease gave very poor results; treatment of silicone grease with ethyl acetate followed by addition of ethanol and decantation of solvent removed an oily fraction and left a residue of grease which has always, so far, proved very satisfactory. The acetate-washed grease from a 'poor-quality' batch was superior even to the best quality unwashed grease, and we have, therefore, used acetate-washed grease in all our subsequent work. We find a mixture comprising 60 per cent 'Celite 545' and 40 per cent acetate-washed silicone grease to be satisfactory for applications.

Difficulties were encountered in the analysis of hexadecanol–octadecanol mixtures, and of brominated technical methyl oleates, at 265° C., owing to slight thermal decomposition of each 'load' of sample, which after a series of tests eventually gave a column so full of charred decomposition products that its efficiency was impaired. In order to reduce the temperature to a more tolerable level, it was considered necessary that the resistance of the column should be reduced so that the inlet pressure could be brought down from about 40 cm. mercury (as hitherto) to, say, 4 cm. mercury. This was achieved by replacing the 'Celite 545' with sodium chloride crystals; the crystals (A.R. grade) were mixed with about 5 per cent of acetate-washed silicone grease. The mixture can be packed into columns quite conveniently; the grease remains on the surface of the sodium chloride crystals even at high temperatures, and the resistance of the 3-ft. column[1] is such that the inlet pressure is 4 cm. mercury when the outlet pressure is 2 cm. mercury. Analyses of hexadecanol–octadecanol mixtures can be carried out at 190–200° C., under which conditions the column can be used for considerable periods. The use of these columns reduces the working temperature for a given separation by about 60° C., and gives separations which are rather better than those obtained with 'Celite'/silicone grease columns at the higher temperatures.

Instead of the straight-wire catharometers previously used, we now have coiled platinum wire catharometers in a small glass envelope, which are about five times as sensitive; a small detachable fraction collector is available for isolating condensate corresponding to any unrecognized maxima on the records, so that unidentified fractions can be analysed by other means, for example, infra-red spectroscopy, mass spectrometry.

We are building a much longer column (20 ft.), with a compact zig-zag shape so that it will fit into the lagged heating cylinder. We hope this will give reasonable flow-rates and will prove effective in separating even more difficult mixtures.

A detailed account of this work will soon be submitted for publication elsewhere.

Interaction between Metal Ions through Anions

In order to overcome experimental difficulties in determining polarizing absorption spectra of substances in the crystalline state, one of us (R. T.) devised a new apparatus, which consists in principle of a polarizing microscope and a sector photometer[1]. By means of the apparatus, we have been determining the dichroism of metallic complexes[2] and aromatic compounds[3]. In this communication we wish to report on the anomalous dichroism of crystals of some compounds showing unusually deep colours.

According to X-ray analysis[4], the crystals of $\mathrm{Pt(NH_3)_2Br_3}$ consist of infinite chains, each containing alternate planes of $\mathrm{Pt^{II}(NH_3)_2Br_2}$ and octahedra of $\mathrm{Pt^{IV}(NH_3)_2Br_4}$. Cohen *et al.*[5] supposed from crystallographic and magnetic examination that the crystals of $\mathrm{Pd(NH_3)_2Cl_3}$ might involve similar chains, in agreement with the results of the X-ray analysis[4]. Quantitative measurement of dichroism with a crystal of $\mathrm{Pd(NH_3)_2Cl_3}$ has been carried out by Tsuchida–Kobayashi's microscopic method[1] in the visible and ultra-violet. The absorption measurement shows that the crystal absorbs at much longer wavelengths than does either of the component complexes. Referring to absorption with the electric vector along the *c*-axis, that is, in the direction of the chains, $\mathrm{Pd^{II}—Cl—Pd^{IV}—Cl{-}{-}Pd^{II}{-}{-}}$, as *c*-absorption, and absorption with the electric vector perpendicular to the *c*-axis as *a*-absorption, then we find that the *c*-absorption is very bathochromic and fairly hyperchromic to the *a*-absorption; the *c*-absorption, exhibits an absorption band at about 40 × 10^{13} sec.$^{-1}$ which is not observed with the *a*-absorption. This band may be considered as a kind of charge-transfer band[7] principally due to the chain, $\mathrm{Pd^{II}{-}{-}Cl—Pd^{IV}—Cl{-}{-}Pd^{II}{-}{-}}$.

$\mathrm{Pt(en)Cl_3}$ may be supposed to be a compound of a similar type. On oxidizing with ammonium persulphate an aqueous suspension of $\mathrm{Pt(en)Cl_2}$ or evaporating a mixed solution of $\mathrm{Pt(en)Cl_2}$ and $\mathrm{Pt(en)Cl_4}$, red, plate-like crystals of $\mathrm{Pt(en)Cl_3}$ are formed. Its properties are similar in many ways to those of $\mathrm{Pt(NH_3)_2Br_3}$ and $\mathrm{Pd(NH_3)_2Cl_3}$, showing that the compound should be formulated as $\mathrm{[Pt^{II}(en)Cl_2][Pt^{IV}(en)Cl_4]}$. The crystal is strongly dichroic; purplish-red and pale yellow with the electric vector along and perpendicular to the *c*-axis, respectively. Since the crystal of $\mathrm{Pt(en)Cl_3}$ has been found to exhibit absorption at far longer wave-length than any of the component complexes, the complexes in this crystal should be under some specific forces. The dichroism measurement indicates that the *c*-absorption is very bathochromic and hyperchromic to the *a*-absorption. These relationships may be readily understood, assuming that the crystal involves infinite chains, $\mathrm{Pt^{II}{-}{-}Cl—Pt^{IV}—Cl{-}{-}Pt^{II}{-}{-}}$, along the *c*-axis. Thus the absorption band between 50 and 65 × 10^{13} sec.$^{-1}$ with the *c*-absorption, which is not observed with the *a*-absorption, is supposed to correspond to a charge-transfer band due to the interaction between platinum atoms in different oxidation states.

Black crystals of $\mathrm{Cs_2AgAuCl_6}$ are known to contain another type of infinite chain consisting of alternate planes of $\mathrm{Au^{III}Cl_4}$ and linear anions, $\mathrm{Cl—Ag^{I}—Cl}$. Dark-brown crystals, $\mathrm{(NH_4)_3AgAuCl_7}$, are obtained, following the same procedure, except that ammonium chloride is used instead of cæsium chloride. Similarity in the properties of the crystals to those of the cæsium compound suggests that the former involves similar chains of $\mathrm{Cl—Ag^{I}—Cl{-}{-}Au^{III}(Cl_4){-}{-}Cl—}$, and might be formulated as $\mathrm{(NH_4)_2AgAuCl_6.NH_4Cl}$. The crystal has been found to absorb at much longer wavelengths than would be expected for the component complexes. It has also been found that the *c*-absorption is very bathochromic and fairly hyperchromic to the *a*-absorption. These relationships, which are similar to those for crystals of $\mathrm{Pd(NH_3)_2Cl_3}$ and $\mathrm{Pt(en)Cl_3}$, seem to agree with the above assumption that the crystal of $\mathrm{(NH_4)_3AgAuCl_7}$ may contain infinite chains of $\mathrm{Ag^{I}—Cl{-}{-}Au^{III}{-}{-}Cl—Ag^{I}—}$ along the *c*-axis. Thus the absorption at 55 × 10^{13} sec.$^{-1}$ for the *c*-absorption may be assigned to a kind of charge-transfer band due to the above chains.

It seems to be the general rule that for compounds of the above type a charge-transfer band is observed with the electric vector along the infinite chains. This may be taken as evidence for strong interaction between metal atoms in different oxidation states through the halogen. The interaction also seems to be closely related to the unusual stability of the groups, Cl—Ag^{I}—Cl and Pd^{IV}(NH$_3$)$_2$Cl$_4$, in these crystals.

Kornerupine from Rannu, Uttar Pradesh, India

KORNERUPINE, a rare magnesium–aluminium borosilicate, is reported for the first time from India. It occurs in a small band of coarse biotite-schist in the pre-Cambrian pink biotite-gneisses, about a mile and a half north-west of Rannu (24° 53′ 45″ : 83° 13′), Dudhi *tahsil*, Mirzapur District, Uttar Pradesh.

The kornerupine prisms occur in aggregates, which are sometimes radiating. Well-developed crystals with the characteristic faces were not noted. The mineral is light to dark grey, has a semi-vitreous to greasy lustre and breaks with an uneven fracture. Its hardness is 6–7 (Mohs's scale); specific gravity of a fairly pure lump, 3·27. In thin sections, the mineral is colourless, non-pleochroic, with one set of indistinct, prismatic (110) cleavages. Fractures transverse to the elongation direction, usually parallel, are common. The refractive indices determined in sodium light at room temperature (32° C.) are $N_x = 1{\cdot}6755$ ($\pm$ 0·0015), N_y and $N = 1{\cdot}6905$ ($\pm$ 0·0005); $N_z - N_x = 0{\cdot}015$. $2V_x$ determined on a four-axis Federov stage is 17° (± 1). Prismatic sections show straight extinction, and are length fast. The optic axial plane is parallel to (100); $c = X$, $b = Z$, $a = Y$.

Thin sections of the kornerupine aggregates show, in places, intergrowth with a few grains of green spinel and colourless corundum, both of which are occasionally surrounded by narrow plates of sapphirine (colourless to pale blue pleochroism). Euhedral sapphire and irregular grains of rutile are often present. Radial cracks are common around zircon inclusions. Two small sillimanite needles were noted within the kornerupine in one of the sections.

Some parts of the biotite schist are rich in thin aggregates of short sillimanite needles; here spinel and corundum are rare and kornerupine appears to be absent. Where kornerupine is well developed, spinel and corundum occur only in minor amounts. The felspathized schists do not show kornerupine and the associated minerals.

Kornerupine has been reported previously in association with sapphirine, gedrite, corundum, sillimanite, andalusite, etc.[1]. The Rannu occurrence is apparently the only one in which the mineral is associated with green spinel. Further work on the mineralogy and paragenesis of the kornerupine is in progress.

Mr. B. J. Skinner, of the Department of Geology, Harvard University, has confirmed the identification of the mineral by X-ray analysis and I thank him for the same. This communication is published by permission of the Director, Geological Survey of India.

A New Type of High-Voltage Machine

THE Van de Graaff high-voltage generator is limited as to its current output by the electrostatic charges which can be carried on moving belts. If a belt could be made to carry charged condensers instead of such surface charges, the current output would become much greater.

This can be achieved in the following way. A series of condensers is attached to or incorporated in an endless moving belt and it is so arranged that they become charged on passing a certain point (*A*, Fig. 1), but later become connected in series as they travel away (*B*). In this way, it should be possible to add voltages together and generate very high potentials.

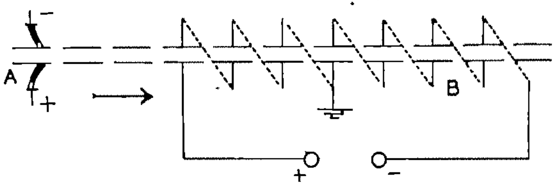

Fig. 1

To test the principle, thirty 8-kV. porcelain tubular condensers of capacity 0·001 mfd. were mounted between two disks of 'Bakelite' board (30 cm. in diameter) forming a circle near the periphery. The terminals of the condensers were connected to brass segments fastened to the outer rims of the disks, and the whole system was mounted on an axle and driven by a motor. Two brushes (at the bottom of the machine) connected to a 7-kV. d.c. supply charged the condensers as they passed. Over the upper half of the disks a set of stationary wire links was provided which connected in series the thirteen condensers that at any moment happened to be at the top. The middle of this set of links was earthed to minimize sparking from either end.

On rotating the wheel at 750 r.p.m., a discharge occurred between blunt wires up to a distance of 11 cm., corresponding to a potential difference of at least 80 kV. It thus appears that very high voltages can be built up almost additively in this way, and with suitable capacity quite heavy currents should be available.

Dr. J. E. Best has kindly directed our attention to an earlier reference[1] in which the same principle has been employed before, chiefly for the purpose of isolating circuits, but with no reference to the production of high voltages.

We have now constructed a larger machine at Newcastle in which the condensers are stationary and the electrical 'contacts' (0·5-mm. air gaps) are caused to rotate. Twenty condensers are used, each 1·5 mfd., and their terminals are connected to two circles of brass segments 18 in. in diameter, one above the other, surrounding the horizontal disk carrying the rotating contacts. As this disk rotates, thirteen of the condensers are connected at any instant through the sparking contacts, so that their voltages add together. The disk, which is made of 'Tufnol', is driven by a motor at 600 r.p.m.

Charging the condensers is carried out by a pair of contacts connected through slip rings to a d.c. charging voltage. The brass sectors are spaced to prevent sparking between them, giving an on/off ratio of 0·52.

The machine operates smoothly at charging voltages of 1·8–2·8 kV. and gives a steady current to an X-ray tube of 5–10 m.amp. The step-up ratio was rather less than expected. Thus, charging at 2·3 kV., the open-circuit output was found to be 26 kV. instead of the calculated 30 kV. When current was drawn from the machine the voltage dropped by 2·3 per cent per m.amp. instead of the 1 per cent calculated. This may, in part, be due to the rather unsteady discharge at small currents.

Preliminary observations of the voltage wave-form indicate that instead of each pulse being of a steady 'square wave' shape, it is broken up into about ten separate discharges. This is probably connected with the irregularity of sparking across air gaps.

This communication is published in the hope that others with wider resources will continue to investigate machines of this kind. We have no desire to reserve the field.

Artificial Increase of Electrical Breakdown Strength of Air at Low Pressure in the Region of 300 Mc./s.

It has been known for some time[1,2] that the presence of a d.c. bias voltage can, under certain conditions, modify the electrical breakdown strength of air at low pressures and ultra-high frequencies. Published information, however, has been restricted to exploration at very small gap-lengths and pressures in excess of about 59 mm. mercury. Further measurements have now been made covering a range of pressures from 5 to 120 mm. mercury, and of gap-widths from about 1 to 4 mm., at two frequencies, 227 and 379 Mc./s. Under these conditions, the superposition of a moderate d.c. stress on the ultra-high frequency alternating stress can increase the ultra-high frequency breakdown stress quite considerably.

If the breakdown strength of a gas is examined as the frequency of the applied stress is increased, two discontinuities are found to occur during the diminution of strength which has been observed to take place between very low and ultra-high frequencies. These are generally believed to mark the regions where the average amplitudes of oscillation of free ions and electrons respectively become comparable with the width of the gap. As soon as it becomes possible for an electron, for example, to have a free life in excess of half a period of the applied stress, then the conditions necessary for the rapid build-up of an electron 'avalanche', the prerequisite of breakdown, are attained more readily. The measurements reported here refer to a region where this condition exists. If, under this condition, steps are taken to increase the rate of loss of free electrons in the gap, for example, by applying a constant d.c. stress, so that free electrons are being constantly 'captured' by the anode, then the onset of breakdown will be delayed, even though in alternate half-periods the total stress is increased. The effect will not be noticed at any frequency so low that the avalanche has to be formed during one half-period for breakdown to occur.

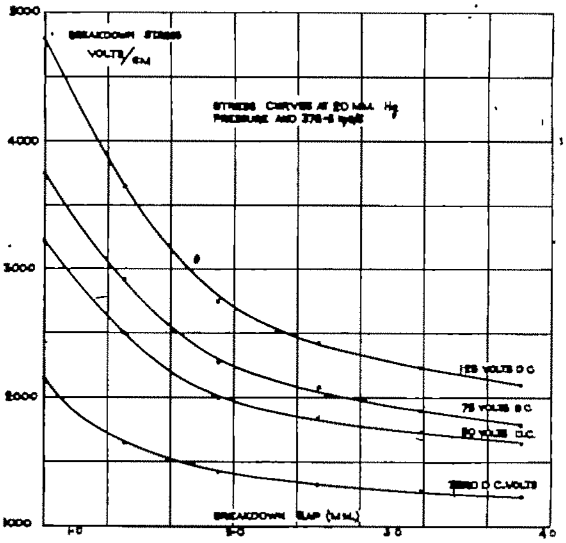

Fig. 1

The scale of the effect is illustrated in Fig. 1, which shows typical results obtained under one set of conditions. The effect is large enough to find practical application as an inhibitor of breakdown in electronic equipment required to operate at high altitudes, particularly if space is restricted, so that gap-widths cannot be increased.

Measurements were made using an evacuated resonant concentric line, which itself contained the breakdown gap, the alternating and direct supplies to which were isolated by conventional means. Ultra-high frequency voltage was measured by means of a small probe and diode rectifier, the probe being situated in the line, in the plane of the gap. Calibration was carried out at lower voltages, where it was possible to use a directly-connected diode rectifier.

The full results, and a quantitative analysis based on the above theory, are being published elsewhere.

Acknowledgment is made to the Chief Scientist, Ministry of Supply, for permission to publish this communication.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, December 6

University of London (at the Postgraduate Medical School of London, Ducane Road London, W.12), at 4 p.m.—Dr. Donald Hunter: "Hazards of Handling Toxic Substances in Industry".*

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Applications and Limitations of Electronic and Other Computers".

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. Cedric Marsh: "Aluminium as a Bridge Material".

Royal Institute of Chemistry, London Section (joint meeting with the London Section of the Society of Chemical Industry, in the Chemistry Lecture Theatre, University College, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. J. Grange Moore: "The Value of Work Study to the Chemical Industry".

Tuesday, December 7

Ross Institute of Tropical Hygiene, Industrial Advisory Committee (in the Council Chamber of the Rubber Growers' Association, 19 Fenchurch Street, E.C.3), at 2.15 p.m.—Discussion on "The Training of Laymen in Tropical Hygiene"

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Symposium on "High Buildings".

University of London, British Postgraduate Medical Foundation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Prof. F. Bergel: "Some Chemical Aspects of Abnormal Growth". (From a series of Lectures on "The Scientific Basis of Medicine".)*

Society of Chemical Industry, Plastics and Polymer Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Prof. P. J. Flory: "The Structure and Properties of Polymers".

Institution of Mechanical Engineers, Education Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "Recruitment to the Engineering Profession from the Secondary Grammar Schools".

Wednesday, December 8

Physical Society, Colour Group (in the Physics Department, Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 2.30 p.m.—Mr. J. D. Moreland: "An Investigation of Peripheral Colour Perception by Direct Comparison between Peripheral and Foveal Vision"; Dr. M. Gilbert: "Acuity to Coloured Letters".

British Society for the History of Science, Philosophy of Science Group, Northern Branch (in the Senate Committee Room, The University, Manchester), at 4.30 p.m.—Sir Geoffrey Jefferson, F.R.S.: "Personality Changes in Cerebral Lesions".

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. C. C. Hall and Mr. A. H. Taylor: "Design and Operation of a Fluidized Pilot Plant for the Fischer–Tropsch Synthesis".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Dr. Archibald Clow: "Distinguished Men of Science".

Institution of Electrical Engineers, Education Discussion Circle (joint meeting with the Education Group of the Institution of Mechanical Engineers and the Institute of Physics, at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Kinetic Theory of Gases for Engineering Students".

Thursday, December 9

Physical Society, Optics Group (at the Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 2.30 p.m.—Dr. A. Maréchal: "Improvement of Contrast of Details in Optical Systems by Filtering Spatial Frequencies"; Dr. E. H. Linfoot: "On the Information Theory of Optical Images".

Institution of British Agricultural Engineers (at the Smithfield Show and Agricultural Machinery Exhibition, Richmond Hall, Earls Court, London), at 3 p.m.—Mr. C. Culpin: "Ventilated Silos for Grain Drying and Storage on the Farm".*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. F. P. Bowden, F.R.S., and Mr. K. Singh: "Irradiation of Explosives with High Speed Particles and the Influence of Crystal Size on Explosion"; Miss A. L. Bailey and Mr. J. S. Courtney-Pratt: "The Area of Real Contact and the Shear Strength of Monomolecular Layers of a Boundary Lubricant".

Physical Society, Low Temperature Group (in the Science Museum Lecture Theatre, Exhibition Road, London, S.W.7), at 5 p.m.—Dr. N. Kurti: "Nuclear Alignment".

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. J. K. Matthews: "Note on the 'Optimum Degree' of Coal Washing".*

Sir Thomas Middleton Memorial Trust (at the University of London, Senate House, London, W.C.1), at 5.30 p.m.—Prof. Kenneth Mather, F.R.S.: "Fundamental Science in Agricultural Research" (Second Middleton Memorial Lecture).*

University of London, British Postgraduate Medical Federation (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Prof. A. Haddow: "Theory and Application of the Nitrogen Mustards". (From a series of Lectures on "The Scientific Basis of Medicine".)*

University College, London (in the Chemistry Theatre, Gower Street, London, W.C.1), at 6 p.m.—Sir George Pepler: "Geddes' Contribution to Town Planning".*

Society of Chemical Industry, Microbiology Group (in the Large Hall of the Medical Society of London, 11 Chandos Street, London, W.1), at 6.15 p.m.—Meeting on "Industrial Uses of Enzymes".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Prof. George Macdonald: "The Medical Implications of the Volta River Project"

Friday, December 10

Association of Applied Biologists (in the Physics Department, Imperial College, Imperial Institute Road, London, S.W.7), at 10.55 a.m.—Scientific Papers.

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Dr. W. B. Carlson and Mr. J. D. McKean: "Cylindrical Pressure Vessels: Stress Systems in Plain Cylindrical Shells and in Plain and Pierced Drumheads".

Society for Analytical Chemistry, Biological Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.15 p.m.—Annual General Meeting. 6.30 p.m.—Scientific Papers.

Institution of Chemical Engineers, Graduates and Students Section (at Caxton Hall, Westminster, London, S.W.1), at 6.30 p.m.—Prof. F. Morton: "The Training of the Chemical Engineer".

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Scientific Papers.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Charles Ellis, F.R.S.: "Coal and Smokeless Fuels".

Saturday, December 11

British Mycological Society (in the rooms of the Linnean Society of London, Burlington House, Piccadilly, London, W.1), at 12 noon—Annual General Meeting. 2.30 p.m.—Dr. J. Ramsbottom: "Mycology and the Amateur" (Pearson Memorial Lecture).

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. David Diringer: "The Origins of the Alphabet".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Master to teach General Science to Cambridge Overseas School Certificate level, at Markham College, Lima, Peru—The Director, Personnel Department, British Council, 65 Davies Street, London, W.1, quoting "Markham" (December 7).

Senior Lecturer (with a good honours degree, or equivalent, in mechanical engineering, and with some practical experience in industry and teaching) in Mechanical Engineering—The Principal, Wigan and District Mining and Technical College, Wigan (December 7).

Assistant Coal Survey Officer, Scientist Grade I or II (with a good honours degree, or equivalent, in chemistry or fuel technology, and preferably with experience in industry, laboratory control and the critical assembly of scientific data), at the Coal Survey Laboratory, Sheffield—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/860 (December 10).

Assistant Experimental Officer (preferably graduate in chemistry or physics) required for the Soil Survey of England and Wales to work on clay mineralogy by X-ray and thermal methods—Rothamsted Experimental Station, Harpenden, Herts (December 11).

Assistant Lecturer, Grade B, in the Pharmacy Department, to teach mainly physical and inorganic chemistry to degree standard—The Principal, Brighton Technical College, Brighton 7 (December 11).

Grassland Agronomist (Scientific Officer or Senior Scientific Officer grade); a Grass Breeder (Scientific Officer grade); a Cereal Breeder (Scientific Officer grade); and Assistants to a Cytologist and Grass Breeder (Assistant Experimental Officer grade), at the Welsh Plant Breeding Station, Aberystwyth—The Registrar, University College of Wales, Aberystwyth (December 11).

Microanalyst (preferably with previous experience in microanalysis) in the Department of Organic Chemistry—The Registrar, The University, Leeds (December 11).

Agricultural Economist (graduate, preferably with qualifications in economics or agriculture) in the Agricultural Economics Department—The Registrar, Wye College (University of London), near Ashford, Kent (December 13).

Scientist, Grade III (with a good honours degree or equivalent qualification in a science subject, and preferably with a sound background in geology or chemistry), in the Coal Survey Laboratory, Newcastle, for work which will include the preparation of detailed reports on the structure and physical and chemical properties of the coal seams covered by the laboratory—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/874 (December 17).

Assistant Experimental Officer in the Department of Scientific and Industrial Research, Road Research Laboratory, Harmondsworth, Middx, for editing technical publications—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.728/54A (December 18).

Lecturer in Education—The Registrar, The University, Liverpool (December 18).

Metallurgist (with a first- or second-class honours degree) at the Ministry of Supply Royal Aircraft Establishment, Farnborough, Hants, to undertake metallographic work on fatigue of metals with special reference to effects of different microstructures—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F 807/54A (December 18).

LECTURER, Grade II, or ASSISTANT LECTURER (with an honours degree in botany with subsidiary zoology) IN BOTANY, at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (December 20).

BIRMINGHAM CHEMICAL CO., LTD., RESEARCH FELLOW (with some research experience in organic chemistry) IN CHEMISTRY, to work on the chemistry of flavouring and aromatic materials—The Registrar, The University, Sheffield 10 (December 31).

J. LYONS FELLOW (graduate in chemistry, and preferably with industrial experience) IN ANALYTICAL CHEMISTRY—The Acting Registrar, The University, Birmingham 15 (December 31).

SCIENTIFIC OFFICER (qualified geneticist, preferably with mycological experience) IN THE GENETICS DEPARTMENT—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford, Herts (January 1).

UNIVERSITY LECTURER (with an honours degree in some branch of natural science and experience in teaching) IN VETERINARY ANATOMY—Dr. A. S. Watt, Botany Department, University of Cambridge, Downing Street, Cambridge (January 1).

CHAIR OF BOTANY, and a LECTURER IN BACTERIOLOGY—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (January 8).

PROFESSOR OF MATHEMATICS, and a PROFESSOR OF CHEMISTRY, at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, January 29)

AGRICULTURAL OFFICERS (with either (*a*) a university degree involving specialization in soil conservation and at least one year's practical postgraduate experience) or (*b*) a university degree in agriculture or an allied subject and with at least two years postgraduate study or experience of soil conservation), in the Gold Coast Local Civil Service, for duties connected with land-use and anti-erosion measures—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W 1, quoting BCD 63/13/04.

ASSISTANT EXPERIMENTAL OFFICER (with at least H.S.C. or equivalent and a good general knowledge of electronic equipment, and preferably with some laboratory experience and familiarity with pulse techniques) at Fort Halstead, Kent, to assist in the development of high voltage pulse circuits, and to be responsible for a small electrical measurements laboratory—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 303/WGE/2.

ASSISTANT METEOROLOGIST (with H.S.C. or equivalent in mathematics or physics, and preferably with experience in forecasting) in Nigeria—The Crown Agents, 4 Millbank, London, S.W.1, quoting M3B/34743/TA.

CHEMISTS (2) (with a first- or second-class honours degree, or equivalent) at the Central Laboratory, Chiswick—Staff Officer (F/EV.514), London Transport, 55 Broadway, London, S.W.1.

ELECTRICAL ENGINEERS and PHYSICISTS (with at least H.S.C. (science) or equivalent) at the Ministry of Supply Radar Research Establishment, Malvern, Worcs, for research and development work on radio and electronic equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.330/54A.

EXPERIMENTAL OFFICER (preferably with a pass degree in chemistry, or at least H.S.C. (science) or equivalent), to be a member of a team carrying out research on inorganic materials, and to control junior staff carrying out routine physico-chemical measurements—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 72/WGE.

JUNIOR SCIENTIFIC OFFICER (with an honours degree in science, pharmacy or biology) for duties which will consist of technical work in the Blood Transfusion Service laboratories—The Director, Blood Transfusion Service, Roby Street, Manchester 1.

MISTRESS (with an honours degree) to teach zoology to university entrance and scholarship level, and to share in the teaching of general science in the Middle School—The Headmistress, London Haberdashers' Aske's School, West Acton, London, W.3.

PHYSICIST (with a good honours degree, preferably with some research experience and a knowledge of electronics) to continue research on the drying of yarn packages—The Secretary, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester, quoting P.5.

REGIONAL TRIALS OFFICER, to work at Leeds University Farm, Headingley Hall, Yorks; and an ASSISTANT TRIALS OFFICER, to work at Norfolk Agricultural Station, Sprowston—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge

RESEARCH ASSISTANT (honours graduate, preferably with research experience) IN ORGANIC CHEMISTRY—The Secretary, University College, Exeter.

SCIENTIFIC OFFICERS (with a first- or second-class honours degree in chemistry, and preferably with an interest in the phenomena of crystal growth, detonation or combustion), to study problems connected with the generation of detonation in high explosives—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 108/WGE/34.

SENIOR LECTURER IN PHYSICS—The Clerk, Northern Polytechnic, Holloway, London, N.7.

SENIOR LECTURER (with research experience in the electrochemical aspect of the subject) IN PHYSICAL CHEMISTRY; a SENIOR LECTURER (with good industrial experience) IN CHEMICAL ENGINEERING; a LECTURER IN BIOLOGY to teach up to B.Sc. ancillary subject standard; a Grade B LECTURER IN CHEMISTRY; a SENIOR LECTURER (with good industrial experience) IN TELECOMMUNICATIONS; a Grade B LECTURER IN ELECTRICAL ENGINEERING; a LECTURER IN PHYSICS, and a Grade B LECTURER IN MATHEMATICS—The Clerk to the Governing Body, Battersea Polytechnic, London, S.W.11.

TECHNICIAN IN THE ZOOLOGY DEPARTMENT—The Secretary, Royal Holloway College, Englefield Green, Surrey.

UNIVERSITY STANDARDS AND THE SOCIAL BACKGROUND

AN article by R. K. Kelsall on the social background of the higher Civil Service in Britain, in the current issue of *The Political Quarterly*, is based on data obtained as part of a wider study to be published next year. The article suggests that there has been a marked alteration in the social background pattern of candidates presenting themselves for examination, and that the main hope of ultimately securing a more equal representation of those originating in the lower social strata still lies in more widely dispersed educational opportunities, and in the maintenance and possible expansion of the present more liberal policy of promotion from the ranks. It recognizes that, before the Second World War, most successful candidates had been at the University of Oxford or of Cambridge, due largely to the fact that relatively few candidates who had been to other universities presented themselves. The other universities are, however, better represented in post-war candidates generally, though most of them still contribute very much less than the appropriate share of competitors for entry to the administrative class, and thus to some extent contribute to the lack of social balance among the entrants.

Some further light is thrown on this question, which clearly may affect the ability of the administrative class both to draw on the full reserve of intelligence in the population and to maintain full touch with the citizens it serves, from a recent broadsheet, "Background of the University Student", issued by Political and Economic Planning (No. 373 ; November 8, 1954). The broadsheet compares the results of a survey at one of the two ancient universities, two English provincial universities, a university college, a college of the University of Wales, and a college of the University of London in 1952–53 with those of a previous survey at the same institutions in 1947–48. In both surveys the information required was extracted from university records, and afterwards arranged and analysed on a similar basis.

As might be expected, on account of the departure of ex-Service students, there was a marked shift towards the younger age-groups for men students in the second survey ; but no clear conclusions regarding the effect of national service on the age at entry can yet be drawn. Some institutions seem to bring most of their students up before they have done their national service, while others, notably the ancient universities, bring them up afterwards. The proportion of British students whose homes are near the universities they attend is still fairly high, except at Oxford and Cambridge ; but it has fallen steadily since the Second World War. At London, the percentage of students with homes within thirty miles of the University increased from 47·4 per cent in 1937–38 to 56·2 per cent in 1947–48 and fell to 52·7 per cent in 1952–53 ; for other English universities and university colleges (excluding Oxford and Cambridge) the corresponding figures are 64·0, 58·4 and 43·7, and for Wales 64·7, 53·5 and 48·2.

The P E P surveys show that while the proportion of men students entering the ancient university from other universities or technical colleges remained almost unchanged (22 per cent in 1952–53 compared with 21 per cent in 1947–48), the percentage entering from fee-paying schools decreased from 52 to 46, while the percentage of students from non-fee paying schools (local authority schools) increased from 21 to 27 per cent; for women students similar figures were observed—a decrease from 51 to 47 per cent and an increase from 30 to 38 per cent, respectively. At one provincial university and at the university college there was a striking increase in the proportion of students coming from other universities and technical colleges, and at the London college where, in 1947–48, 34 per cent of men and 28 per cent of women students came from this source, there was a slight increase. At the other provincial university there was little change in the percentage of men students so recruited, but an increase in the proportion of women students; while at the Welsh college the percentage of men and women students so recruited declined from 11 per cent and 5 per cent, respectively, to 5 per cent and 1 per cent.

This second survey confirms the observation made in the first survey—that, whereas ex-Service students at the ancient universities coming from independent public schools had not been seriously affected by competition from the former pupils of grammar schools, competition from school leavers seemed to be growing more severe. At four of the other institutions the shift was in the same direction, although at the London college it was slight, and at one other institution it was slight. For women students the changes have been in contrary directions. But apart from these aberrations, the representation of the State secondary schools at the universities of Britain has been strengthened during the five years. For men students only the ancient university now has a larger proportion coming from fee-paying schools, and the gap is narrowing; apart from foreign and Colonial students, the Welsh college and the university college are virtually preserves of the State schools, and a recent survey by P E P of the University College of North Staffordshire showed that an average of 81·2 per cent of its men students and 79·8 per cent of women students came from State schools.

Analysis of the occupations of parents of United Kingdom students was based on seven groups: professional, administrative, proprietors and managers; forces, police, fire service, etc.; farmers; personal services; retail traders, innkeepers, etc.; clerks, shop assistants, salesmen, etc.; and manual workers. At all four institutions there has been a shift towards the latter end of the scale; even at the ancient university the last two groups increased their representation by seven per cent for men and one per cent for women at the expense of the first two groups. Elsewhere among men students the representations of the last two groups have risen from about a third to about one-half of the total, and there has been a similar change among women students; but even at the Welsh college it is still true that women students tend to come from higher social groups than their male colleagues.

Further analysis of the first occupational group indicates that in the five-year period the proportion of students whose fathers are higher Civil servants or senior officials in local government has decreased, and also the proportion of students whose fathers are in business, either on their own account or holding senior managerial positions. A recent analysis of students registered at Hull University College (now the University of Hull) showed that thirty-four per cent are of working class origin, while the earlier P E P survey showed that this figure for the ancient university was seven per cent and at provincial universities twenty per cent. The broadsheet also quotes from two other recent studies of the social and educational backgrounds of students covering more limited fields. H. Jenkins and D. Caradog Jones's study of "The Social Class of Cambridge Alumni" showed that the proportion of public school men at Cambridge rose during the second half of the nineteenth century, being eighty-two per cent during 1850–99, until the growth of local authority secondary schools brought about a decline to sixty-eight per cent in 1937–38. Since only the ablest pupils from grammar schools went up to Cambridge, these students had the best academic record over the whole period 1752–1899, although they were less successful in their careers than the products of famous public schools. Schools or families of high social standing had a definite relation to securing posts of distinction, though not those of the highest importance; but apart from this bias, successful students at Cambridge usually did well in later life.

C. A. Anderson and M. Schnaper's survey of the social background of Oxford and Cambridge students was based on individuals at the university between 1850 and 1900, and indicated the extent to which the older universities provided for the education of men who achieved or inherited eminence in later life. Men who made their names in government service had the most diversified educational background; but at that time the older universities did not dip very deeply into the social pyramid. The most noticeable feature was for Oxford and Cambridge to have the lion's share of great men, with a marked tendency for sons to follow in their fathers' footsteps.

Replying in an adjournment debate on local authority awards to university students in the House of Commons on November 17, the Parliamentary Secretary to the Ministry of Education, Mr. Dennis Vosper, made some relevant comments. As a result of university expansion, the number of students of any age-group going to a university was about double the pre-war number, and in each age-group a much greater cross-section of the social strata was represented. Even if there was not equality of opportunity from area to area, he said, we have moved much nearer to equality of opportunity so far as the income of parents and social background are concerned. In 1953 the universities took 1,250 open scholars, 2,000 State scholars and 10,000 students with local authority awards; more than 70 per cent of the 18,000 students entering the universities in that year were thus in receipt of awards.

Mr. Vosper stressed the great increase in local-authority awards, which in 1938 were only 1,500, and in 1953 had cost almost £6 million compared with £2 million in 1948. While university and State scholarship awards are for students of outstanding academic ability, local authority awards are intended to assist students of good all-round ability for whom it is in the public interest that a university education should be provided. The procedure at present in force, he said, leaves responsibility with the local authorities, which are asked to consider all candidates with a minimum academic standard, but are left some discrimination and particularly with reference to the headmaster's report and interview panel. Only six out of 146 authorities in Britain do not now accept the minimum standard laid down in the Circular of 1952, and Mr. Vosper thinks that, apart from the six authorities noted, there has been much improvement in uniformity of standard and equality of opportunity. The universities at the moment do not feel able to undertake the work involved in making an award dependent on acceptance by a university, and while it might be possible for the Ministry of Education to select the two thousand State scholars each year on academic achievements, he does not think it possible for the Ministry to select ten thousand students of all-round ability.

Without over-stressing the value of these partial surveys, it is clear that these trends, of which the University Grants Committee, from its last quinquennial report, is clearly aware, pose problems of which the universities must increasingly take account pending the completion of the inquiries now being carried out by the Committee of Vice-Chancellors and Principals and by P E P itself. The former inquiry is expected to furnish, in due course, a mass of information about the educational and social origins of university students, as well as about their qualifications, awards held and courses followed, and the reasons for rejection of unsuccessful candidates. The second is concerned with graduates—and especially with graduates in industry—and should also provide material of use to the universities as well as to industry.

On the evidence now presented, even if the proportion of students coming from homes within a short radius of the provincial universities does not increase, the shift in the social strata from which students are drawn may well accentuate the difficulties which arise when a considerable proportion of students is drawn from homes with no tradition of culture. It is not a problem to be solved merely by the increase in financial grant or by the more generous provision and equipment of libraries and halls of residence.

The inquiry into ways of learning by students of university age which the University Grants Committee has sponsored, and which is being conducted by Sir Godfrey Thomson under the auspices of the University of Edinburgh, should go closer to the heart of the matter. What is involved is an attitude of mind that is endangered by the deficiencies of home life and conditions or by relative poverty, and which also is discouraged by the tendency of the times to rely on the State rather than on individual effort or initiative. It is also in part a question of values; and unless this problem of the attitude to learning and of cultural and intellectual values is faced and solved, there is danger that the State will receive little or no return from the six million pounds now being spent annually on university awards by the local authorities alone.

There are other disturbing consequences at which the surveys already published hint. It may be questioned whether the dominance of students from the State schools will not endanger the full value of the experiment which has been proceeding at Keele for the past four years. Diversity of entry offers, for the moment, a hope of correcting some of the more serious consequences which may flow from the present trend in the background of the university student. At least it may be said that the evidence of the P E P broadsheet affords strong support for caution in regard to university expansion, and endorses the view already expressed by the University Grants Committee that the main immediate task of the universities is consolidation. Adjustments to meet particular needs of the community and the improvement of methods of selection are important indeed; but the primary task is that of so adjusting the teaching work and responsibilities of the university to the changing types of student that successive generations of student will continue to acquire the same secret of learning, to catch the same inspiration, and to carry away with them the same powers of vision and imaginative understanding as did those who in former years entered the universities with greater social and cultural advantages.

THE CONQUEST OF PLAGUE

The Conquest of Plague

A Study of the Evolution of Epidemiology. By Dr. L. Fabian Hirst. Pp. xvi + 748. (Oxford: Clarendon Press; London: Oxford University Press, 1953.) 42*s*. net.

THIS is a comprehensive study of plague. The author, Dr. L. Fabian Hirst, is a microbiologist who, as Lieut.-General Sir William MacArthur writes in a foreword, during a period of twenty-two years has paid special attention to the disease in various parts of the Middle and Far East, particularly in Ceylon.

Part 1 of the book deals with traditional conceptions of the nature of plague. Dr. Hirst reminds the reader that primitive beliefs and observations may hold truths that are only revealed to the man of science centuries later. Instances of this are the epidemics of plague among the Philistines, described in the Old Testament (I Samuel, v, vi), which are associated with the presence of small rodents. The Hebrew word *akbar* may mean rat or mouse. If the civic authorities of London had read their Bible more carefully, they would not have favoured the rat population in ordering the destruction of cats and dogs as possible vectors of plague in 1665. Dr. Charles Singer has pointed out that during the seventeenth century natural causes were first assigned to plague, and even that it was due to the multiplication of minute organisms, a hypothesis not verified for two hundred years.

Concerning the spread of the disease, miasma versus contagion was for centuries the subject of debate, and it was not until the middle of the nineteenth century, when Sir John Simon organized careful investigation of plague outbreaks as recorded in his "Annual Reports" to the Privy Council, that scientific opinion progressed from the conception of a miasma emanating from putrefying filth to a specific chemical poison in air and water, and, finally, to the modern view that specific infections are due to invasion of the body by specific micro-organisms. In his historical narrative Dr. Hirst demonstrates how the study of plague has played an important part in the general evolution of epidemiology. The plagues of London, the Marseilles epidemic of 1720–21, the "Short Discourse concerning Pestilential Contagion" of Richard Mead, which advanced knowledge of the disease and its control by quarantine, all these historical landmarks receive careful attention.

To those engaged in work on plague, whether as research worker, administrator or medical practitioner, the remaining three parts of this work will be of special interest. In these parts the author considers the modern conceptions of the nature of plague, its spread in time and space, its conquest and its international and national control. Here Dr. Hirst has drawn freely upon his own researches dealing with the parasitological and preventive aspects of the disease. It is all most systematically and carefully done. On the vexed question as to whether Kitasato or Yersin discovered the bacillus of plague at Hong Kong in 1894, Dr. Hirst examines the evidence and states (p. 108): "The conclusion must be that both bacteriologists discovered the plague bacillus independently within a few days. Kitasato saw it first, but Yersin, the former *préparateur* of the Pasteur Institute, was probably the more accomplished technician and gave by far the best description of the micro-organism".

There are interesting studies in the book of rats as transmitters of plague, of the classification of the fleas which convey plague, together with a full account of plague among the rodents of the great plains. The author then describes inter-human plague; the temporal spread of plague, together with a consideration of the periodicity of epidemic disease; and the territorial spread of plague. Last of all he discusses administrative measures for the prevention of plague and, from a wealth of experience, points out the difficulties and pitfalls, as well as the successes, of the measures pursued. This portion of the book might have been expanded with advantage; but Dr. Hirst records the chief steps in international control of plague and its prevention, and a second volume would be required to treat the subject exhaustively.

In an epidemiological treatise only brief reference is possible to the successful modern treatment of plague. Formerly, the early injection of a fresh and potent anti-plague serum was the chief method. Since the introduction of the sulphonamides by Domagk in 1935 it has been shown that plague can be successfully treated by certain of these preparations. Later still, some of the new antibiotics, especially streptomycin, have proved even more efficacious. Penicillin, the best known of these, does not act on the plague bacillus.

This erudite work, which investigates many aspects of a deadly but now a controllable disease, is clearly written and can be read with profit by both lay and medical readers. The book is appropriately illustrated and well produced. ARTHUR S. MACNALTY

SCIENTIFIC DESIGN OF ABSORPTION TOWERS

Absorption Towers

With Special Reference to the Design of Packed Towers for Absorption and Stripping. By G. A. Morris and J. Jackson. Pp. xi+158+3 plates. (London: Butterworths Scientific Publications in association with Imperial Chemical Industries, Ltd., 1953.) 30s. net.

THE design of absorption towers is a complicated process owing to the large number of factors involved and the irregular flow conditions which are often encountered; it was not until the middle 'thirties that any success was achieved. The two-film theory was available as a suitable basis; but the real clue to scientific design was given by the development of the comparatively simple grid-packing together with the surprisingly belated recognition of the fact that for best performance it is essential to have uniform liquid flow over the surface of the packing. Even now, mere wetness appears sometimes to be regarded as satisfactory, although this is by no means always the case. While the general principles of design have not appreciably changed since 1937, many improvements have been introduced and much data accumulated. Making full use of these and a great deal of hitherto unpublished information, G. A. Morris and J. Jackson have produced a monograph of outstanding merit. In spite of the complexity of the subject, the clarity of presentation is such that, with the help of this book, anyone with some knowledge of physical chemistry should be able to design an absorption tower.

A brief introduction to the subject of absorption is followed by a chapter on the determination of film coefficients by laboratory methods and by one on packings. Two methods of design—in other words, calculation of the most economical dimensions of the tower and the best type of packing—are elaborated, one using absorption coefficients and the other transfer units, and their relative merits are discussed. Economic factors are treated separately, and a table of economic gas-rates for different packings will be found of much assistance. A very valuable chapter on the mechanical features of design is largely devoted to the important subject of liquid distribution already mentioned, and a number of fully worked-out examples are appended to assist in applying the principles discussed in the main part of the book. To conclude, a glossary is added, in which exception must be taken to the authors' use of the not altogether accurate term 'gas-film limitation' instead of the older and more usual 'gas film control'.

Special features are the comprehensive tables and well-drawn diagrams which supply practically all the facts required by the designer, thereby saving him from the inconvenience of continual reference to bulky volumes of tables. A minor omission is a table of heats of solution, while a welcome item rarely found in British books is an indication of the price of the main components of the plant. Absorption calculations unfortunately require the use of a great many symbols which are difficult to remember; but the reader is helped in the present book not only by a six-page summary at the end of the volume but also by an explanatory list after each important formula, a practice much to be commended. Units are often a source of confusion: the C.G.S., British and metric systems are all used, but the first is confined to the laboratory section. Both British and metric values are given in the tables, the figures being set out with such clarity that a mistake is well-nigh impossible.

One omission, no doubt intentional, is greatly to be regretted—the complete absence of data for the performance of existing large towers and comparison with calculated values. This tends to impart an academic atmosphere to the book, despite its obviously practical nature. The authors emphasize that large towers are difficult to test, that some of the design methods recommended are still tentative, and that it is sometimes desirable to introduce factors of safety; but a few definite figures for the discrepancies actually found would indicate the reliance to be placed on the calculations. Apart from this, the book is a model of the way in which to treat a complex chemical engineering subject and is a particularly good example of the application of science to industry. All chemical engineers will adopt it as a standard work of reference, and all chemical manufacturers should study it. H. E. WATSON

NAPHTHOIC ACIDS AND THEIR DERIVATIVES

Elsevier's Encyclopædia of Organic Chemistry

Edited by F. Radt. Series 3: Carboisocyclic Condensed Compounds. Vol. 12*B*: Naphthalene. (*A*) Compounds Containing One Naphthalene Nucleus. Naphthoic Acids and Their Halogen, Nitrogen, and Hydroxyl Derivatives. Pp. 3965–4560. (Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd., 1953.) £21 net. (Series Subscriber, £18 10*s*.; Complete Subscriber, £16.)

THIS seventh part of Vol. 12*B* makes a useful addition to the section of the Encyclopædia dealing with naphthalene derivatives. The seven parts together already constitute an impressive survey of naphthalene chemistry, but the end is not yet in sight. Part 7 is concerned with the two naphthoic acids and their hydrides and homologues, together with the usual types of acid derivatives, and various substitution products containing halogen, nitrogenous groups, hydroxyl and alkoxyl. Polycarboxylic acids derived from naphthalene will find a place, presumably, in Part 8. As is usual with such a method of treatment, the result is an assembly of information about an assortment of compounds which will appeal to a variety of tastes.

For the natural product chemist there is an interesting review of the recent chemistry of naturally occurring lactones derived from naphthoic acids. These comprise the conidendrins and the constituents of 'podophyllin'. As regards the latter, the structural relationships between podophyllotoxin and picropodophyllin and their derivatives are set forth in a characteristically clear chart of formulæ. These substances have aroused some interest among biologists on account of their destructive action on certain pathological growths. The chemical reader who consults the index may well wonder what is an 'oncolytic' compound. If he refers to the text, he will find that it is a substance with tumour-damaging activity.

For the dyestuffs chemist there are surveys of aminonaphthoic and hydroxynaphthoic acids. The anilide of 2-hydroxy-3-naphthoic acid (Naphthol *AS*) and its applications are fully discussed; many azo dyes derived from this and related compounds are described, and there is a table occupying fifteen pages which summarizes the properties of the many known arylamides of 2-hydroxy-3-naphthoic acid. For the pharmacological chemist there are descriptions of many compounds with local anæsthetic activity derived from the aminonaphthoic acids.

There are the usual references to physical constants, including optical data, and to biological properties as far as these have been recorded. For 1-naphthonitrile, for example, the ultra-violet absorption maxima and Raman frequencies are given, as well as the fluorescence, phosphorescence and magnetic properties, the dielectric constant, the heat of combustion and the density. Its polyploidogenic action is also mentioned. The only misprint which has been noted is an obvious one, in a heading on p. 4009. The high standard of previous parts of this Encyclopædia is well maintained. J. W. COOK

BASIC DYNAMICS FOR STUDENTS OF AERONAUTICS

Introduction to Aeronautical Dynamics

By Prof. Manfred Rauscher. Pp. xv + 664. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 96*s*. net.

AERONAUTICS is, with the possible exception of astronomy, the subject in which the greatest and most diverse applications of classical mechanics are made. These applications cover problems of the dynamics of particles and of rigid and deformable bodies, oscillations of many kinds and the whole field of the mechanics of fluids. Investigations of great difficulty and much technical importance arise in which the system consists of a deformable body (aircraft) in motion through a viscous and compressible fluid (air). Questions of the stability of motion are of great importance, while thermodynamic considerations are essentially involved in the problems of propulsion and of high-speed flight in general. All this implies that aeronautical scientists and engineers must be well versed in dynamical techniques, some of which have indeed been specially devised for the treatment of aeronautical problems, while students must have a thorough training in dynamical fundamentals. It is these fundamentals which the book under review aims to provide.

Dynamical theory may be regarded as composed of three parts: kinematic theory, dynamical principles, and mathematical techniques for the solution of problems. Kinematic theory is based only on pure geometry and the concept of time and is thus not, properly speaking, dynamics at all. However, the analysis of every dynamical problem must begin with a thorough kinematic investigation, and when this has been made and the results assimilated, the application of the truly dynamical principles is usually easy. In my opinion, the importance of kinematics has been greatly under-estimated in recent times. It is therefore pleasing to find that due attention to kinematics is paid in this treatise. The first chapters cover basic kinematics, the dynamics of a particle and the dynamics of sets of particles. Next, Chapters 4–7 give an outline of the kinematics and dynamics of fluids, with sections on vortices and the application of the complex variable, while Chapters 8–9 are concerned with the theory of aerofoil-in two and three dimensions. Chapter 10 deals very briefly (and it must be said, too briefly) with viscosity, turbulence and the applications of dimensional analysis. The next two chapters are concerned with the kinematics and dynamics of rigid bodies, and the final chapters deal with the oscillations of dynamical systems having one or a larger finite number of degrees of freedom.

I can sum up my opinion of this book by saying that it gives a competent account of basic dynamics for students of aeronautical engineering from the point of view of one experienced teacher. Many readers will be disappointed to find that the more advanced topics of aeronautical dynamics, such as the theories of stability and control and of flutter, are not discussed at all. The title of the book is, indeed, rather misleading in this respect.

W. J. Duncan

THE ADVANCE OF PLANT PHYSIOLOGY

Annual Review of Plant Physiology

Edited by Daniel I. Arnon, in association with Leonard Machlis. Vol. 5. Pp. x+400. (Stanford, Calif.: Annual Reviews, Inc., 1954.) 7 dollars.

With the publication of its fifth volume the "Annual Review of Plant Physiology" may claim to be well established. The present volume follows the same lines as its predecessors and contains fourteen articles on different aspects of plant physiology. While some of these cover a wide field, such as that on tropisms and nastic movements (L. Brauner), or deal with subjects of considerable appeal to plant physiologists, such as the long article on photosynthesis (R. Lumby, J. D. Spikes and H. Eyring) with no less than 401 references, that on the connected subject of the photosynthetic function of pigments other than chlorophyll (L. R. Blinks) and the one on the occurrence, formation and inactivation of auxins (S. A. Gordon), others deal with matters of which knowledge is perhaps not so widely distributed, even among plant physiologists. Among such might be included the articles on the physiology of plant tumours (A. C. Braun), dormancy in woody plants (R. M. Samish), the post harvest physiology of fruits and vegetables (W. T. Pentzer and P. H. Heinze), the physiological aspects of fungus diseases of plants (P. J. Allen), and the role of plant physiology in plant geography (H. L. Mason and P. R. Stout). Yet, with the exception of the last-named, none of these articles has less than a hundred references to literature.

Of the subjects dealt with in the present volume, perhaps those in which advances in knowledge are most spectacular concern enzymes. One of these, by W. D. McElroy and A. Nason, is on micronutrient elements in enzyme systems; the other, by D. A. Goddard and H. A. Stafford, deals with the localization of enzymes in the cells of higher plants. A perusal of these reviews cannot fail to impress on the reader the real progress that has been made in these subjects during the past few years. Thirty years ago, that such things as trace elements were essential for plants had scarcely been accepted by plant physiologists in general. Ten years ago, by which time the necessity for trace elements was well recognized, their function was obscure and a matter for conjecture. The article by McElroy and Nason now shows strikingly how widespread is the necessity for one or other of these elements for the activation of enzymes. Iron and copper enzyme systems, as well as some involving magnesium, have been known for some time, but now McElroy and Nason list more than twenty enzymes which are activated by manganese, and they conclude that manganese is the chief metal concerned in general enzymatic decarboxylation and hydrolysis. Zinc and magnesium appear to be similarly involved to some extent. Manganese, though not to the same extent as magnesium, appears also to be required for enzyme actions involving group transference. Copper, iron and molybdenum are concerned with electron-transferring systems.

A few years ago knowledge of the subject here dealt with by Goddard and Stafford was negligible. Now at the end of their article on the localization of enzymes in the cell they list 101 references, 90 per cent of which refer to publications that have appeared not earlier than 1950. The extension of knowledge of enzyme systems to include their localization in the cell has resulted from the new technique of differential centrifugation of cell-free homogenates, by which a partial separation at least of cell constituents such as nuclei, plastids, mitochondria and microsomes is attempted. While the authors of the review show that the results so far obtained must be accepted with caution, it seems clear that the development of this line of investigation gives promise of information of the greatest importance in the not distant future.

Another article dealing with a new development is that on soil conditioners by J. H. Quastel. While the importance of the natural soil conditioner, humus, has been known for centuries and, maybe, thousands of years, it is only during the past few years that the possibility of using synthetic substances for improving poorly aggregated soils has been indicated. This article gives a clear account of the nature of the synthetic soil conditioners and their effects on soil, and will be read with interest by pedologists as well as by plant physiologists.

The remaining two articles are on nutrition by foliar application (D. Boynton), and the mineral nutrition of phytoplankton (B. H. Ketchum). The former, concerned as it is with the effect of sprays, will be of particular interest to pomologists, while the latter will be of special appeal to that growing band of physiologists who use unicellular algae, as providing reproducible material, for their investigations. Once again the editors and contributors are to be congratulated on providing for their fellow plant physiologists a most useful and welcome volume.

Walter Stiles

The World of Learning, 1954

Fifth edition. Pp. xii+1030. (London: Europa Publications, Limited, 1954.) 100*s.* net.

THE fourth edition of the "World of Learning" was published in 1947, and though it was very useful at the time to have this reference book so soon after the Second World War, it was not really so valuable as it at first sight seemed, in that the information relating to a number of countries that had been devastated by the War, was not up to date. The new fifth edition, besides being as up to date as such a compilation as this can be, is a good deal enlarged; in particular, it opens with a new section on Unesco, giving its origins, aims, functions and organization as well as an account of its recent activities, and this is followed by a list of the principal international scientific organizations, with brief statements of their objects and the names of their main officials.

The rest of the book follows the plan of the previous edition. It is divided alphabetically (by English name) into the various countries of the world, and, where the entries for a country are sufficiently numerous, a contents list is given. The arrangement of entries for Great Britain gives an idea of the range of institutions, etc., covered: learned societies and professional associations; research institutes; libraries; museums and art galleries; universities and university colleges; centres for adult and technical education; schools of art, music and dramatic art; and educational trusts. Naturally, the range of headings varies somewhat from country to country. In general, the entry for each institution contains its address, the names of the leading officials and the date of foundation, and for each university a complete list of all the professors is given. Where applicable, the titles of publications issued by the body concerned are listed. A useful section of the book is that on the U.S.S.R., which is twenty-nine pages long; no universities are quoted, but a very full list of the numerous higher educational institutions and research establishments in the U.S.S.R. is given.

The book ends with a fifty-four page index of institutions, with more than two hundred entries per page. There is no name index. Other reference books exist covering universities and the more academic bodies to be found in the various countries of the world, and in this particular field the "World of Learning" is no more comprehensive, probably less so. But where it scores over the other books is in the very complete lists of non-university organizations such as learned societies, professional organizations, museums, etc., and for this it can be recommended.

Public Health Engineering

By Peter C. G. Isaac. (Spon's Civil Engineering Series.) Pp. xvii+277. (London: E. and F. N. Spon, Ltd., 1953.) 36*s.* net.

THE average member of the public in Britain is apt to take things for granted and has little conception of the magnitude and complexity of the undertakings which deal with unhealthy products and supply him with pure water, 10–15 per cent of which he wastes. These and kindred activities are now classed under the heading of public health engineering, and this book under review is a welcome introduction to the subject. Nearly half of it is given up to water, its sources, collection, quality, analysis, treatment and distribution. Fifty pages are devoted to sewage and its purification—the ever-growing problem of river pollution is given a separate chapter—and the methods of treatment of trade wastes are illustrated by a number of specific examples. After discussion of refuse disposal and atmospheric pollution, the author concludes with a chapter on district heating, a subject which scarcely comes under the heading of sanitary engineering but one which is to be welcomed in view of its importance and the necessity of propaganda to induce the British public to revise its ideas on the subject of warming houses.

It is obviously impossible in one small volume to deal with all the subjects mentioned above in any detail, but the author has succeeded in giving an immense amount of information and, in addition, in presenting it in a readable and interesting manner. As the result of a stay in the United States, he has been able in many cases to quote American practice and to compare it with British, and there can be few people, even among sanitary experts, who will find nothing that is new to them. For the benefit of those wishing to go more deeply into a subject, numerous references are given at the end of each chapter. "Public Health Engineering" was written primarily for students and sanitary engineers; but it is to be hoped that it will attract the attention of a far larger circle of readers, since the matters dealt with are of vital importance to all. H. E. W.

Table of Binomial Coefficients

Prepared for the Mathematical Tables Committees of the British Association and the Royal Society, under the Editorship of J. C. P. Miller. (Royal Society Mathematical Tables—Vol. 3.) Pp. viii+162. (Cambridge: At the University Press, 1954.) 35*s.* net.

THIS volume is actually the second of those to appear under Royal Society auspices as a consequence of the Cunningham Bequest of 1928, the first being E. H. Neville's "The Farey Series of Order 1025" (1950). Many establishments have co-operated in its production, including the National Physical Laboratory and the Royal Aircraft Establishment. As the computation of the tables was fairly simple, there is no need for a lengthy introduction. The basis of the calculations was the elementary recurrence formula of Pascal's triangle, and no further details or formulæ have been included.

All the tabulated values are exact, in order to meet the requirements of number theory (the primary object of the Cunningham Bequest). For values of n up to and including 200, every value of the binomial coefficient $\binom{n}{r}$ for each value of r up to $\frac{1}{2}n$ is supplied, and the maximum coefficient (or pair of coefficients) appears in bold type. This tabulation, which forms the main part of the book, occupies a hundred and three pages in all. The remaining sixty pages are devoted to higher values of n, as far as 5,000, with corresponding entries for small values of r only, first up to 12 and then (as n increases) 11, 5 and finally 3.

A page index, showing at a glance where any particular coefficient may be found, is supplied on p. 1, and there is also a list of references to publications used or consulted. The whole book is beautifully produced, in the highest traditions of the Cambridge University Press. J. H. PEARCE

THE JUBILEE OF THE THERMIONIC VALVE

ON November 16, 1904, Prof. J. A. Fleming first described, in British Patent Specification No. 24850, the application of a two-electrode thermionic valve to the rectification of alternating currents of high or, as we now term them, radio frequencies. The jubilee of this invention was celebrated on November 16 last at a special meeting of the Institution of Electrical Engineers, at which lectures on the history and development of thermionic devices were given, and an exhibition of some 240 different types of valves was opened. The widespread interest in the occasion was evident from the fact that the members present filled to capacity the lecture theatre of the Institution.

Earlier in the day, the Marquess of Salisbury, Lord President of the Council, unveiled a plaque to the memory of Sir Ambrose Fleming, F.R.S., at University College, London, the birthplace of the valve, where Fleming was professor of electrical engineering during 1885–1926. Lady Fleming was present at this ceremony, at which Lord Salisbury recalled that this invention of the thermionic valve was the starting-point for the vast developments of the present day in the field of electronics.

During the period November 16–18, an exhibition was held in the Electrical Laboratories of University College, at which were displayed a large and historical collection of lamps, valves and electrical measuring equipment which, together with laboratory and lecture manuscript notebooks and a collection of published works, represented Fleming's wide range of interests and great contributions to electrical engineering. It was very appropriate that the exhibition should include demonstrations of current research in progress in the College laboratories, illustrating new techniques for measurement at very high radio frequencies and the study of wave propagation along conducting surfaces.

The meeting at the Institution of Electrical Engineers was opened by Lord Salisbury, who directed attention to the significance of the discovery of the thermionic valve by Sir Ambrose Fleming, whose inspiration carried him far beyond the work of previous investigators and so enabled him to add further lustre to the record of British scientists. Lord Salisbury referred to the fact that the birth of the thermionic valve was one of the most far-reaching events of the past half-century; and he directed attention to the remarkable technological applications to which the principle of the valve pointed the way. Wireless transmission, broadcasting, television, radar and radio aids to navigation and surveying, he pointed out, have all been exploited within the past few decades; and we appear to be only just at the beginning of a vast new era of the application of electronics to industrial techniques and processes. Many of the necessary processes of modern industry —sorting, testing, measuring, etc.—are fatiguing and boring tasks, and much progress has been made, particularly in the United States, in exploiting the new techniques, which open up a vista of relief from exhaustion and increased leisure for the whole working population. Lord Salisbury concluded his address with the following remarks: "Let us, then, regard this jubilee not only as an occasion for looking back with thanks and admiration to Sir Ambrose Fleming for all that we owe him, and with gratitude to those who have followed him, but also as an occasion for looking forward, for straining forward, towards that land of promise which his genius has brought within our sight, and almost within our grasp".

The president of the Institution, Mr. J. Eccles, then welcomed Lady Fleming and expressed the hope that she would find that the large number of members present had assembled in a sincere effort to pay tribute to the great work of her late husband.

Prof. G. W. O. Howe then delivered a lecture entitled "The Genesis of the Thermionic Valve", in the early part of which he outlined Fleming's early life and education at the University of London and later at Cambridge, where he studied under Clerk Maxwell. While holding an appointment with the Edison Electric Light Co., Fleming visited the United States in 1884, when Edison exhibited an interesting discovery which he had made the year before. He had fixed a metal plate in the bulb of a carbon filament lamp, and he found that a current flowed through a galvanometer connected between the metal plate and the positive terminal of the filament. No current was indicated, however, when the connexion was made to the negative terminal of the filament. This phenomenon, which was afterwards known as the 'Edison effect', was applied to the control of the mains voltage in a power station, but Edison made no use of it for telegraphy. This matter greatly interested Fleming and he conducted several investigations on it from 1890 onwards, in the course of which he showed that a similar but smaller effect was obtained when platinum was used instead of carbon for the incandescent filament.

Nearly ten years later, when Fleming had become scientific adviser to the Marconi Co., he had much to do with the design and equipment of the wireless station at Poldhu, from which the first trans-Atlantic signals were transmitted in December 1901. It was in October 1904, twenty years after his visit to the United States, that it suddenly occurred to him that the Edison effect could be used for rectifying or 'detecting' alternating currents of high frequency, such as those occurring in the circuits of a wireless receiver. After making some confirmatory experiments, Fleming, at the age of fifty-five, applied for a patent for the two-electrode thermionic valve on November 16, 1904. This valve, or diode as we now term it, could be in several forms; but each of these comprised a filament, which could be heated to incandescence, and an insulated metal electrode, both sealed inside an evacuated envelope. Fleming found later that better results in the detection of wireless signals could be obtained when the valve was constructed with a tungsten filament and an insulated copper cylinder surrounding it. Almost concurrently, Wehnelt had noted that if a filament was coated with certain oxides, the emission of electrons was greatly facilitated; hence currents could be obtained with a lower temperature, with corresponding greater sensitiveness and convenience of operation.

The next step in the evolution of the thermionic valve was made by Dr. Lee de Forest, who had been working in the United States on similar lines to Fleming. In 1906, de Forest applied for a patent for a three-electrode valve as a device for amplifying feeble electric currents, by using a voltage on the grid or intermediate electrode to control the current flowing to the plate or anode. A few months later, the patent was extended to cover the use of the three-electrode valve, or 'audion' as de Forest termed it, as a detector of oscillations in a wireless telegraphy receiver.

After these events, a period of several years elapsed before the thermionic valve, in either its two- or three-electrode form, found any great practical use in the reception of wireless signals. This was partly due to the fact that the technique of the production of high vacua had to be considerably improved before valves could be made and used with anything like a reliable performance; but it was also due to the advanced development of such reliable and sensitive devices as the magnetic and crystal detectors. It was about 1913 before H. J. Round in Britain and other workers in the United States began successfully to apply the valve to wireless reception; and it was really during the First World War that the development of the 'hard' or high-vacuum valve was applied successfully on a large scale to the amplification of audio- and radio-frequency currents in radio reception.

The story was continued in a lecture on "Thermionic Devices from the Development of the Triode up to 1939" by Sir Edward Appleton, who emphasized the fact that de Forest's objective was to obtain a sensitive and controllable detector, for which purpose it was considered essential that there should be some residual gas in the audion. Sir Edward pointed out that in the basic de Forest patent, granted in 1908, a radio-receiving circuit is shown with a grid condenser, and this is deemed to be the invention of what is now called cumulative grid rectification. But it still needed some years of investigation by other workers before the mode of action of the three-electrode valve and its remarkable potentialities were fully recognized. Notable in this phase of development was the work of E. H. Armstrong, who described, in papers published during 1914–15, experiments which did so much to elucidate the function of the triode as a detector and to show the advantage of applying back coupling or retro-action to reinforce the oscillations. He also dealt with the use of the three-electrode valve as a generator of oscillations and for reception on the heterodyne beat principle. Armstrong took advantage of the work of Langmuir in obtaining valves with a very high vacuum, and in consequence he found it necessary to use a high-resistance shunt to the grid condenser in order to control the 'squegging' action, which was sometimes troublesome in the reception of signals with hard valves.

In the meantime, workers in other countries were not idle: following a patent in 1911, von Lieben and Reisz described a soft three-electrode valve containing mercury vapour and its use as a relay or amplifier. The British pioneer workers, H. J. Round and C. S. Franklin, after experimenting with these and other soft valves, appreciated the advantages of the high vacuum and produced some notable valves which achieved an outstanding reputation at the beginning of the First World War. Following the lead when the Americans entered the War in Europe, the French workers under General Ferrié developed the celebrated *R*-type hard valve, which had a cylindrical anode and a spiral grid, the filament being along the axis of both.

By the end of the War, the three-electrode valve, or triode, was really understood; but it was the only valve in common use as a detector, amplifier or generator of high-frequency oscillations. Broadcasting was, in fact, started with the triode, although its limitations were by that time well recognized. To reduce the unwanted inter-electrode coupling between grid and anode, A. W. Hull suggested the insertion of another electrode; and it remained for Round to introduce the screen-grid valve, or tetrode, into practical use in 1926. This brought under consideration the phenomenon of secondary emission from the anode; to reduce this, the insertion of a suppressor grid was proposed by B. D. H. Tellegen, of the Philips organization in Holland, who thus became the inventor of the pentode, a valve which has since become very popular for many purposes.

During the period up to 1939, the two-electrode valve of Fleming had been employed almost solely as a rectifier for alternating currents at power frequency; but near the end of this period, this diode came back into use as a high-frequency detector; and also, by means of a suitable circuit, as an automatic control of the grid bias on the 'variable mu' type of valve, permitting the output from the receiver to be maintained at a sensibly constant level.

In the later portion of his lecture, Sir Edward referred to the use of the thermionic valve as an electrical instrument. While ordinary triodes were found very suitable for use in, for example, E. B. Moullin's valve voltmeter, it required special design to produce an electrometer triode with a low input capacity and a very high insulation resistance for the grid. Such valves have, however, been found very useful for a number of purposes such as the study of the change in the earth's electric field due to lightning flashes. In the period up to 1939, the valve had become a most versatile and important tool in many fields of scientific research, quite apart from its application to radio communication, broadcasting and television.

At the evening session of the meeting at the Institution, Dr. J. Thomson gave a lecture on "Developments in Thermionic Devices since 1939". It was first pointed out that during the period under review the valve has undergone extensive development, not only for radio reception, but also as an amplifier to give a steadily increasing power output in transmitters of all types. But the uses of the valve have now become very widespread; and in analysing the functions of thermionic devices in modern electronic equipment, Dr. Thomson directed attention to the fact that the valve is like an engine, performing the same duties in the electronic machine as the steam or internal combustion engine in the mechanical machine. The unique property of the electronic device is its high speed of operation. This has been exploited by the radio scientist in the development and use of microwave systems; while others are using valves for control and computing mechanisms.

Dr. Thomson made specific reference, with the aid of slides, to the various types of valve now in use for the generation and reception of centimetre-wave frequencies; and gave an explanation of the action of the klystron and its analogous relationship with the travelling-wave tube and the magnetron. He also illustrated the recent developments in the miniature and sub-miniature types of valve, and the various steps which have been taken to make valves increasingly reliable in operation. Dr. Thomson pointed out that valves are already completely reliable so far as home radio and television sets are concerned; at the same time, he emphasized the fact that the universal application of electronic machinery in offices, factories and in means of transport depends largely upon the reliability of electronic components.

The lecture closed with a brief speculation as to the future. While some may be of the opinion that an electronic valve or tube should never be used if it can be avoided, it is an essential item for high-speed operation. While this speed is still too low for many modern applications, it is likely that in the next half-century this speed of control will be exploited in all fields of activity.

An expression of thanks to the lecturers was made by Mr. C. W. Oatley, chairman of the Radio Section of the Institution, and by Sir Gordon Radley, vice-president of the Institution; Sir Gordon remarked that if Sir Ambrose Fleming could have been present at this jubilee celebration of his invention, he would have been thrilled by the very large family that has sprung from the original and simple diode, and the variety of parts they have played in peace and in war.

R. L. Smith-Rose

PHYSICAL RESEARCH LABORATORY, AHMEDABAD

By Dr. K. R. RAMANATHAN

Director

A RESEARCH laboratory for the study of cosmic rays was started at Ahmedabad in 1947 by a private body called the Karmakshetra Educational Foundation. During the past seven years, with generous assistance from the Ahmedabad Education Society, the Government of Bombay, the Ministry of Scientific Research and the Atomic Energy Commission of India, the Physical Research Laboratory, as it is known, has steadily expanded and widened its scientific interests. The foundation stone of its new building was laid by Sir Chandrashekhar Venkata Raman in 1952 and the building was opened by the Prime Minister, Shri Jawahar Lal Nehru, on April 10, 1954.

The building is in the Gujarat University campus, and facing it are the laboratories of the Ahmedabad Textile Industry's Research Association (see *Nature*, Sept. 25, p. 578) and the Lalbhai Dalpatbhai College of Engineering. In a large field, west of the Laboratory, are a 72-ft. wind tower, radio masts and an experimental hut for ionospheric research. The central wing of the Laboratory runs east to west and has two floors. Nine research rooms on the first floor and five on the ground floor are accommodated in this wing. For cosmic ray measurements, one of the research rooms on the first floor has a specially constructed light roof of aluminium. A conveniently accessible terrace on the first floor is used for observational work on the sun and the sky. The central wing of the Laboratory on the ground floor connects at one end to the library and a seminar room. The staircase is situated at the western end of the central wing, where there is also an experimental area with a high ceiling. This is flanked by the workshop, the dark room, the store and a preparation section. Adjoining the workshop is a yard and a carpentry shop.

The initial research programme of the Laboratory was decided by the interests of its principal scientific workers: Prof. Vikram Sarabhai, who started the Laboratory, is concerned with studying the time variations of cosmic rays and the light they throw on the sources of cosmic rays; the present writer is interested in problems of atmospheric physics such as atmospheric ozone and its distribution, night air-glow and problems of the ionosphere. The programme of the Laboratory at the moment comprises an integrated study of the different kinds of radiations which are received on the earth and their geophysical consequences. In order to carry out such a programme satisfactorily, two more Departments, one of Theoretical Physics and another of Radiophysics and Electronics, were added in 1949. With thirty research workers drawn from different parts of the country, the Physical Research Laboratory at Ahmedabad is now an established centre for advanced study and research in experimental and theoretical physics in western India.

Department of Atmospheric Physics. In India the Council of Scientific and Industrial Research has for many years supported a research scheme for the study of atmospheric ozone and the weather, and, with the co-operation of the India Meteorological Department, three ozone-measuring stations have been established at Delhi, Mt. Abu and Veraval. Work done in India has shown that the amount of ozone in low latitudes up to 20° N. is small and nearly constant in different seasons, and is little affected by weather. On the other hand, in European latitudes, the amount of ozone is larger and more variable from day to day. In Indian latitudes north of 20° N., during the months May–November, the amount of ozone continues to be small and steady, but increases markedly in winter. Between December and April there are large quasi-periodic increases of ozone associated with variations of high-level winds in the upper atmosphere. Studies of the vertical distribution of ozone in the atmosphere that have been made over Delhi, Mt. Abu, Poona and Kodaikanal have established that the tropical troposphere which extends to nearly ten miles above the ground contains only small quantities of ozone, but that, as one goes to higher latitudes, more and more ozone comes down to lower levels. The change from the tropical type of ozone distribution to the extra-tropical type appears to take place in the region of high-level jet streams of westerly upper winds. The study of the correlated variations of atmospheric ozone at a number of places promises to throw light on the general circulation of the atmosphere at levels not otherwise easily accessible to observation.

An important discovery has resulted from careful ozone measurements made during moonlight. It has been shown that there is a daily variation in the amount of ozone in Indian latitudes, there being an excess of ozone during the night.

Besides the work on the ozone content of the atmosphere, a large number of radiosonde ascents have been made at Ahmedabad to study the daily and the day-to-day variations of temperature and humidity in the upper atmosphere. They have considerably increased our knowledge of the upper atmosphere over north-west India, and have also been of help in interpreting the corresponding variations of cosmic ray intensities.

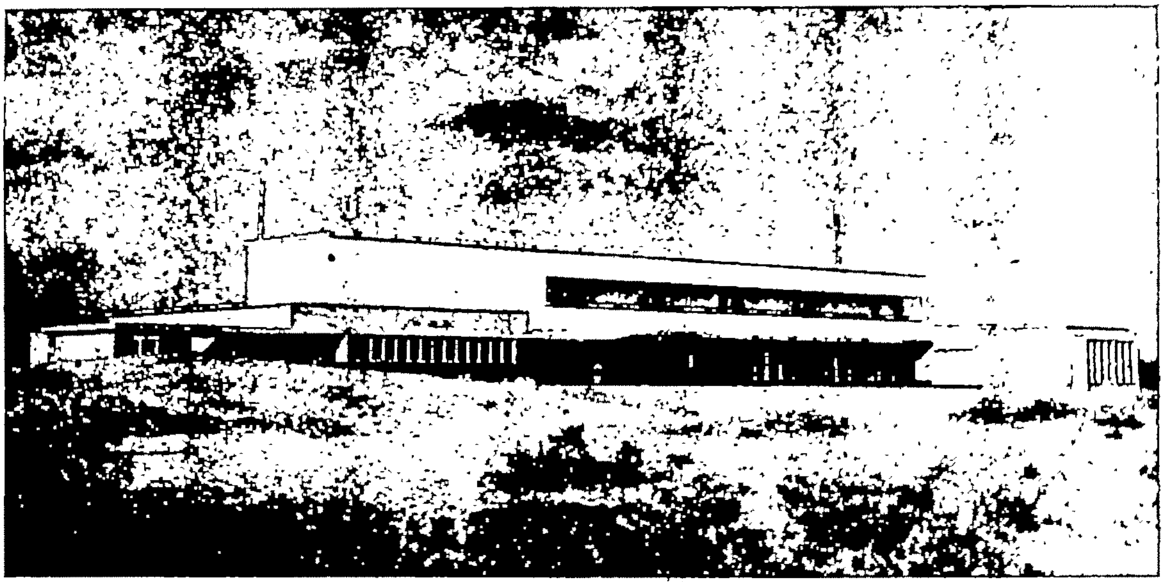

Photo. by J. M. Shah

Physical Research Laboratory, Ahmedabad

Studies of twilight sky intensities and polarizations have been undertaken using a photo-multiplier. Measurements on the brightness of the sky in different narrow spectral bands have been carried out at Mt. Abu from sunset to a time when full night conditions have set in. Observations show that, after the sun has gone down 5°–6° below the horizon, there is very much more light coming from the sky than can be explained by the primary scattering of sunlight by the molecules of the upper atmosphere. Part of this is undoubtedly due to night air-glow, but there are possibly other causes, such as scattering by meteoric dust in the upper atmosphere. The problem is under investigation.

Cosmic Ray Department. Under Prof. Sarabhai, the Cosmic Ray Department has established continuous recording stations at Ahmedabad, Kodaikanal and Trivandrum. The second and third, almost at the magnetic equator, represent a mountain and a sea-level station, respectively. Observations collected over three years have shown clearly the value of directional studies with Geiger counter telescopes, with which the daily variations are larger and capable of more unambiguous interpretation than with ionization chambers.

In interpreting the experimental results, there are several factors which have to be taken into account: the atmospheric pressure, the heights of levels where cosmic-ray mesons are created, and the atmospheric temperatures near these levels. Work done at the Laboratory indicates that atmospheric mass absorption is the only important meteorological factor so far as the daily variation of the meson intensity is concerned, and its influence can be corrected for by using the known variations of atmospheric pressure. The geomagnetic effect being small, it is possible to attribute the daily variation of meson intensity, corrected for barometric pressure, to an anisotropy of the primary cosmic rays. For the daily variations of the soft electronic component and the atmospheric shower intensity there are, however, more complicated relationships with meteorological factors. These involve, besides the total mass of the air column, its vertical distribution, depending on atmospheric temperatures at different levels.

The pressure-corrected daily variation of meson intensity, which can be attributed to the anisotropy of cosmic rays, has a maximum in the forenoon at low latitudes. The dependence of this maximum on local solar time has been interpreted as indicating that the anisotropy is under solar control. This is also supported by an analysis done by Sarabhai and Kane of the published cosmic-ray data of the Carnegie Institution stations. The analysis has led to the discovery that the daily variation of the meson intensity, corrected for pressure, undergoes large changes of world-wide character, and that these changes are connected with those in solar activity. As the simplest explanation, it has therefore been suggested that a small portion of the primary cosmic radiation originates in the sun. Sarabhai and Kane have also directed attention to a geomagnetic explanation for the difference in the daily variation studied at different latitudes and with apparatus pointing to different directions.

A comprehensive programme is now in progress at the Laboratory for developing an optimum technique for the study of the anisotropy of the primary radiation.

Department of Theoretical Physics. This Department, which was first under Dr. A. B. Bhatia and is now under Dr. Vachaspati, is concerned with fundamental theory and the problems of nuclear structure. Dr. Vachaspati and his colleagues have been interested in the question of nuclear radii and have recently suggested, on the basis of electron scattering and Coulomb energy data, that the nucleus might have some negative charge at its centre along with positive charge outside. Calculations are also being done on the scattering of π-mesons by nuclei, energy-levels of μ-mesonic atoms, alpha-decay lifetimes and some aspects of field theory. The Department gives regular courses in theoretical physics to post-graduate students.

Department of Radiophysics and Electronics. Work in this Department, which is now under Dr. U. D. Desai, is directed towards the systematic recording and analysis of the characteristics of the ionosphere at Ahmedabad with an automatic multi-frequency recorder. Hourly records of reflexions of radio waves have been obtained since February 1953, and monthly summaries of the data are published in the *Journal of Scientific and Industrial Research*. At present, Ahmedabad is one of the three stations in India at which round-the-clock observations of the ionosphere are being made.

Besides the main regions, E, F_1 and F_2, of the ionosphere, two intermediate layers between E and F_1 have been found to be regularly recorded, and these are being studied. A comparative study is also being made of the critical frequencies and heights of F_2 reflexion at different latitudes in India, and also the effect of magnetic storms and solar flares on the F_2 region. In addition, the true heights and thicknesses of the F_1 and F_2 regions, and the total electron content in a vertical column of the atmosphere up to the height of maximum electron density, are being examined. A radio pulse transmitter, aerials and recording receiver have been built for studying winds in the ionosphere on the lines of Mitra's method.

PERMANENT MAGNET ASSOCIATION

CENTRAL RESEARCH LABORATORY

THE research activities of the Permanent Magnet Association were conducted for many years by co-operative investigations carried out in the works laboratories of its members. The technical collaboration so fostered has many advantages and such work still continues; but in 1941 centralized research, more removed from the distractions of production problems, was commenced with the equipment housed temporarily in the Physics Department of the University of Sheffield, by courtesy of the University authorities.

In 1946 it became possible to proceed with the building of the first story of a laboratory in Brown Street, Sheffield. This building, opened in 1946, gave facilities for pilot manufacture and heat treatment of magnet castings. Physical, chemical and metallographic laboratories were included, and also a workshop for apparatus and instrument construction.

The original plans have recently been completed by the addition of a second story, and on November 8 representatives of the technical Press, of local industrial concerns and of scientific establishments were invited to view the laboratories and to see some of the work now in progress. The new story includes a heat-treatment laboratory, a library and conference room and also gives additional office and storage space. These extensions, in conjunction with the e-arrangement of the older laboratories, now give a rationalized lay-out of the various sections.

The laboratory is approved by the Department of Scientific and Industrial Research but is not grant-aided, being supported wholly by the manufacturing firms who are members of the Association. The director is not only responsible for the work of the Central Laboratory, but also keeps in close touch with the research activities in the laboratories of the members, thus promoting the continuation of that technical collaboration which has been found fruitful throughout the history of the Association. In these circumstances it would be invidious to distinguish between the technical progress of the Central Research Laboratory and of the Association as a whole.

The principal activity of the Laboratory lies in the development of new permanent-magnet materials and the improvement of the properties and of the economy of processing of the existing alloys. The high energy ($BH_{\max}$) of modern magnet alloys is only obtainable by the use of large percentages of expensive metals, and so the achievement of maximum properties with minimum consumption of alloy is a constant objective. In 1945 it was possible to introduce 'Alcomax II' with average $BH_{\max}$ 4·5 megagauss-oersted and coercivity 575 oersted. Work on a wide range of additions to the basic alloy led in 1948 to the discovery of the beneficial effects of niobium in small amounts. There followed the introduction of 'Alcomax III' with $BH_{\max}$ 5·0 megagauss-oersted, coercivity 670 oersted, and of 'Alcomax IV' with $BH_{\max}$ 4·5 megagauss-oersted, coercivity 750 oersted. Shortly afterwards it was predicted on theoretical grounds that similar anisotropic alloys with a common crystal axis instead of random orientation should have markedly improved properties. Considerable experimental work led in 1952 to laboratory production of 'Columax', with remanence 13,000–14,000 gauss, $BH_{\max}$ more than 8·5 megagauss-oersted, and coercivity 750–850 oersted. The production of the structure necessary for such properties requires that the solidification of the alloy should take place progressively from one face of the casting. A mould which is chilled on one face and heated on other faces to temperatures approaching the solidus temperature of the alloy is necessary. The study of the thermal conditions for a completely columnar structure and of practical means of obtaining columnar castings is an important part of the current work. The maximum properties obtained in the laboratory cannot yet be realized in quantity production, although marked improvement on random crystal material is possible.

The metallography of 'Alcomax' alloys is not fully understood, but the diagnosis of faults in composition or heat treatment by microscopic observation of the incipient development of two-phase structures has been of practical utility. Some remarkable macroscopic structures can be seen by the polishing and etching of 'Columax' specimens, which demonstrate well the effect of crystal orientation on the reflexion of light from an etched surface.

High-energy permanent magnets of complex composition have led to secondary problems. Magnets tend to smaller and smaller sizes, and the measurement of the normal B–H curve criteria on small pieces has required the development of modified apparatus and methods. New methods of chemical analysis have been necessary for alloys of increasing complexity. Electrolytic separation and the use of absorptiometric and chromatographic techniques have been found necessary. Here also the collaboration with works laboratories has been valuable, and the analytical methods standardized by the Association have been approved and published by the British Standards Institution.

With the support of the Electrical Research Association, investigations are proceeding on the stability of magnetization under extremes of temperature. Very little knowledge existed until recently on the effect of sub-zero temperatures, although there is now a definite practical interest down to −70° C. The nickel–aluminium magnet alloys are very resistant to demagnetization by heating, and so the observation in 'Alcomax' magnets of losses of magnetization to the extent of 1–4 per cent due to cooling to about −70° C. was surprising. It has been found that the coercivity of 'Alcomax' after normal heat treatment decreases reversibly with decreasing temperature between 0° and −180° C., but that this change can be reduced by modifications to the heat treatment. Any stabilization or ageing process which brings the working values of B and H for the magnet within the main hysteresis loop also eliminates the loss due to cooling.

Hysteresis motors are coming into general use as components of gyro and servo systems. The rotors of these motors require a hysteretic material of the permanent magnet type; but the operating conditions are not well defined and there have been few measurements made with non-saturating magnetic fields or of rotating rather than alternating hysteresis. It has become customary to use for these rotors one of the magnet steels, frequently in a metallurgical condition other than fully hardened. A large programme of measurements is in hand to provide a body of design data for this application and to check the optimum magnetic and metallurgical conditions for maximum utilization of material.

Fundamental physical research on high-coercivity materials has always occupied an important place in the work of the Central Research Laboratory of the Association. Measurements of magnetostriction and of anisotropy coefficients on 'Alcomax' alloys and their interpretation in the light of current ferromagnetic theory have been the basis of a series of published papers. This work, in conjunction with work elsewhere by X-ray and electron diffraction techniques and the electron microscope, has led to a better understanding of the origin of the preferred-domain orientation and high coercivity which is the basis of the nickel–aluminium–cobalt–iron alloys used for high-energy permanent magnets.

CHEMISTRY OF MUSCLE CONTRACTION

Contraction of Muscle without Fission of Adenosine Triphosphate or Creatine Phosphate

As Hill[1] has pointed out, it still remains to be proved that adenosine triphosphate is the immediate source of energy in the contracting muscle. The analytical methods now available for determining the individual phosphate fractions of animal tissues have made it possible to re-examine directly the relation between contraction and breakdown of adenosine triphosphate. Experiments are here reported which suggest that muscle can in fact do work under certain well-defined conditions without the decomposition of an energetically equivalent amount of adenosine triphosphate or creatine phosphate.

The crucial experiments were carried out on a slow muscle, the rectus abdominis of the frog, *Rana temporaria*, at 0° C. A slow muscle and a low temperature were chosen in order to reduce the rate of chemical processes. Pairs of muscles from the same animal were used in each experiment. One, left and right alternately, was stimulated while the second served as control. Otherwise both were treated in the same way. The muscles were stimulated either electrically, or by immersion in isotonic 0·765 per cent potassium chloride solution, or by immersion in 0·5 per cent caffeine–Ringer solution. The work done during contraction was calculated from the kymographic record[2]. After the attainment of contraction, the muscle and the control were quickly placed in liquid nitrogen. No contraction occurred in the controls on freezing as the muscles were thin and cold.

To determine the phosphate fractions, the frozen tissue was ground in a cold mortar and trichloroacetic acid solution was added to the frozen muscle powder. The mixture was allowed to melt at 0° C. and centrifuged. Creatine phosphate was determined in the supernatant according to Eggleton and Eggleton[3]. Two more samples were chromatographed on paper by a modification[4] of the methods of Eggleston and Hems[4] and Krebs and Hems[5] for the determination of the following six fractions: (*a*) creatine phosphate, (*b*) inorganic phosphate, (*c*) adenosine triphosphate, (*d*) adenosine diphosphate, (*e*) an 'unknown' fraction ('Dritte Fraktion' of Fleckenstein and Janke[6]), and (*f*) the total acid-soluble organic phosphate minus creatine phosphate. Recovery of added creatine phosphate, adenosine tri- or di-phosphate was quantitative[7]. The fractions $c + d + e$ form about two-thirds of f. The techniques are described in full elsewhere[4,6,8].

In the case of the potassium contracture, no significant change of adenosine tri- or di-phosphate occurred at 0° C. or 20° C., but the amounts of creatine phosphate decreased (Table 1). These findings are in agreement with the assumption that adenosine triphosphate decomposes but is almost at once regenerated by the transfer of phosphate from creatine phosphate to adenosine diphosphate. They are not in agreement with Bendall's[9] view that the

Table 1. CHANGES IN PHOSPHATE-CONTAINING COMPOUNDS AS A RESULT OF A SINGLE CONTRACTION AT 0° C. CAUSED BY IMMERSION FOR 45 SEC. IN 0·765 PER CENT POTASSIUM CHLORIDE SOLUTION

(All phosphorus estimations on each sample were carried out in duplicate and comparisons were made between the left and right side of the rectus abdominis from the same frog (*Rana temporaria*). The mean difference was obtained from the differences between the test and control of each pair of experiments. The muscles were cut off the support and frozen in liquid nitrogen. For further details see ref. 6). The absolute amounts and ratios of the various fractions vary with the time of year, so the controls in Tables 1–4 are not directly comparable with each other

adenosine triphosphate-level must fall during contraction.

In the case of the caffeine contracture, a decrease of adenosine triphosphate and creatine phosphate and an increase in adenosine diphosphate and inorganic phosphate occurred at 20° C. At 0° C. the results were similar to those with potassium chloride (Table 2). The results show that the methods used were capable of detecting changes in the concentrations of these compounds.

In the case of contracture due to electrical stimuli (12 stimuli per sec. by condenser discharge and direct stimulation of the muscle), no change in adenosine tri- and di-phosphate took place at 20° C., whereas the concentration of creatine phosphate fell (Table 3). At 0° C. no adenosine tri- or di-phosphate or creatine phosphate disappeared; but there was a decrease in fraction (*f*) and an increase in inorganic phosphate. This was sufficient to account for the work done on the assumption that the inorganic phosphate was derived from an 'energy-rich' phosphate, and that the efficiency approached 100 per cent. The nature of the organic phosphate that released inorganic phosphate under these conditions is unknown. It is being investigated. It should be pointed out that the period of contraction on electrical stimulation was 0·9–1·2 sec. and that creatine phosphate breakdown occurred after electrical stimulation for several seconds even at 0° C. When potassium chloride or caffeine was the stimulant a much longer period of incubation of 15 sec. or $2\frac{1}{2}$ min. was required because, *inter alia*, of the relatively slow penetration of these agents.

These experiments support the view that muscular contraction can occur without decomposition of adenosine triphosphate or creatine phosphate[2]. However, the expected decrease in the concentration of creatine phosphate present, assuming 100 per cent efficiency, was only 3 per cent of the total creatine phosphate present. Statistical analysis shows that the chance that this decrease occurred but had escaped detection was only 28 per 1,000. Nevertheless, it was thought desirable to find conditions where the expected change in the concentration of creatine phosphate would be greater on a percentage basis. Pre-incubation for 20 min. at 20° C. with 5×10^{-4} *M* 2 : 4-dinitrophenol produced such conditions. This treatment reduced the creatine phosphate content of the tissue from about 11 μmoles per gm. to 0·6 μmoles per gm., but the muscles still contracted vigorously even at 0° C. (though they were unable to relax). In this material the expected decrease in creatine phosphate concentration was 50 per cent or more; yet there was again no significant change in the adenosine tri- and di-phosphate and creatine phosphate fractions, while the fraction *f* decreased and the inorganic phosphate increased (Table 4). It should be noted that the low level of creatine phosphate rendered any rephosphorylation of adenosine diphosphate from this source thermodynamically highly improbable.

To exclude the possibility that creatine phosphate or adenosine triphosphate was resynthesized at the expense of respiration during the duration of the experiments (1·3–3·5 sec.), the rate of recovery of creatine phosphate, after electrical stimulation for 1 min., was measured. At best, resynthesis was thirty times lower than required for the non-disappearance of creatine phosphate. A similar large discrepancy was obtained from calculations based on the rates of respiration of stimulated muscle and maximum possible values for the efficiency of oxidative phosphorylation.

The results show that, though a breakdown of creatine phosphate (and under some conditions even of adenosine triphosphate) can be observed after contractions lasting several seconds or more produced by electrical stimulation, potassium chloride or caffeine, such a breakdown did not occur in the rapid contractions at 0° C.

In conclusion, it may be said on the basis of the electrical experiments at 0° C., especially those in the presence of dinitrophenol, that muscle has been shown to do work without the fission of energetically equivalent quantities of adenosine triphosphate or creatine phosphate. Inorganic phosphate was, however, liberated during contraction, from an unidentified precursor in just sufficient quantities to supply the required energy, provided the phosphate undergoing fission was 'energy-rich'.

It follows that there is a source of energy in living muscle which either can synthesize adenosine triphosphate from the diphosphate at a rapid rate (like creatine phosphate), or which is closer to the process of contraction than the breakdown of adenosine triphosphate. Whether this source is the 'phosphate-bond energy' of an unidentified compound or an entirely different kind of source such as ionic concentration gradients[10] remains to be investigated.

A full account of this work will be published elsewhere.

In the following communication, Dr. W. F. H. M. Mommaerts presents results obtained independently which are concordant with those presented here and elsewhere[2,6,8].

Is Adenosine Triphosphate broken down during a Single Muscle Twitch ?

THE widespread assumption that muscular contraction is caused by enzymatic hydrolysis of adenosine triphosphate is based on two types of not entirely direct evidence[1–3]. On one hand, biochemical research has demonstrated that metabolic processes such as respiration and glycolysis, which indirectly support muscular activity, do so by virtue of the synthesis of adenosine triphosphate. On the other hand, various interactions between adenosine triphosphate and muscle proteins have been described, culminating in the contraction (induced by adenosine triphosphate) of actomyosin threads and extracted muscle fibres discovered by Szent-Györgyi. Yet a direct demonstration of the role of adenosine triphosphate in living muscle has not been given, notwithstanding A. V. Hill's[4] call for such a straightforward approach.

In the present work, of which a full account will be submitted to the *American Journal of Physiology*, an attempt has been made to demonstrate the breakdown of adenosine triphosphate and of phosphocreatine during the course of a single twitch. Experiments were carried out on symmetrical pairs of leg muscles of the turtle, *Pseudemys elegans*, one of which was stimulated, while the other acted as the control. At a chosen moment, early or late in the contraction, the muscles were suddenly immersed in liquid propane, cooled to −185° C., by means of a mechanical device effecting this immersion in about 6 m.sec., the twitch itself lasting 2–8 sec. at low temperature. The muscles were loaded so as to perform approximately maximal work and their movements were recorded on a revolving drum. In all instances, the cooling procedure caused immediate stopping of the muscle at the moment of immersion, whereas temperature measurements inside muscles, with a thermocouple and cathode ray oscillograph, showed precipitous cooling without delay.

It was anticipated that if the contraction of muscle were caused by a fission of adenosine triphosphate or phosphocreatine, this fission would amount to 0·3–

0·5 μmol. per gm. of tissue[2,3]. In designing the analytical procedures, it was held that it would be difficult to prove or disprove the occurrence of such a degree of breakdown of adenosine triphosphate or phosphocreatine by direct determination of these substances, since they occur in amounts which are large in proportion to the change anticipated to take place in one twitch. It was decided, instead, to determine the possible breakdown products, adenosine di- and mono-phosphate and creatine. In addition, creatinine was also determined, although its formation would be rather improbable; finally, pyruvate was determined to cover the possibility of a rephosphorylation of adenosine diphosphate by phosphopyruvate formed, for example, from phosphoglycerate. The analyses of creatine and creatinine were carried out colorimetrically, by the Voges–Proskauer and the Jaffe reactions, respectively. All the other analyses were carried out by differential enzymatic spectrophotometry: adenosine monophosphate with adenylate deaminase; pyruvate with lactic dehydrogenase and reduced diphosphopyridine nucleotide; adenosine diphosphate by phosphorylation with phosphopyruvate and pyruvate phosphokinase, followed by assay of the pyruvate so formed. The results of assaying inosinic acid as a possible end-product (measured with 5-nucleotidase, nucleoside phosphorylase and xanthine oxidase) are still subject to some experimental uncertainty, but are in all probability negative.

In Table 1, results of these analyses are collected for various times throughout the contraction and the relaxation phases. It is seen that in no case was any significant change found in the amount of adenosine mono- or di-phosphate or creatine. Creatinine and pyruvate were likewise unchanged. Fluctuations of the individual pairs—always within 0·1 μmol. and usually within 0·05 μmol.—are entirely random, and a systematic variation of the expected magnitude is therefore excluded.

It may be said with certainty that a breakdown of adenosine triphosphate or phosphocreatine could not have been reversed by metabolism, since both aerobic and anaerobic recovery are known to occur only well after a single twitch. The experiments described were carried out anaerobically, in a mixture of nitrogen and carbon dioxide or in helium; a few aerobic experiments gave the same result.

Table 1. CHANGE IN CONCENTRATION OF THE MAIN REACTION PRODUCTS (IN μMOL PER GM.) DURING THE COURSE OF MUSCLE TWITCH

Mean change during relaxation phase	− 0·01	0·00	− 0·01

Since we are at present investigating the possible role of other nucleotides, it is considered premature to discuss in full the possible implications of these results for our understanding of muscle. However, the possibility of a new "Revolution in Muscle Physiology"[6] is clearly discernible.

OBITUARY

Dr. R. S. Wilson

ROBERT SHARP WILSON, Fellow of the Research School of Physical Sciences in the Australian National University, died in Canberra on October 4 at the age of thirty-eight. He was a leading member of the team working under Prof. M. L. Oliphant on the design of a 10-GeV. proton synchrotron.

Born in Lancashire, Wilson graduated at Cambridge in 1938 and continued with research in nuclear physics at Liverpool under Sir James Chadwick. Throughout the war years he was a scientific officer at the Telecommunications Research Establishment, Malvern. At the beginning he worked on the development and use of radar in night-fighters for air interception. Later he became a valued member of the Radio Countermeasures Division engaged on denying to the enemy much of the advantage of his radar and radio systems. This work had a significant effect in reducing Allied losses, both in air operations over Germany and in the invasion of Europe.

In 1945 Wilson joined Prof. Oliphant at Birmingham, where he was responsible for the radio-frequency system of the 60-in. cyclotron. While there he completed his thesis for Ph.D. (Liverpool), making an analysis of the theory of cyclotrons. In 1951 he was the first Fellow to be appointed in the Research School of Physical Sciences of the newly established Australian National University. Here he investigated the possibilities of various radio-frequency systems for the several high-energy particle accelerators that were under consideration, and at the time of his death was working on the system chosen for the 10-GeV. air-cored synchrotron. He visited laboratories in the United States and Britain in 1953 in order to study the latest developments in synchrotron design and report on the possible value to the Canberra machine of the revolutionary strong-focusing system.

Wilson was much valued for his clear thinking on policy and his fundamental approach to the physics of the problems with which both he and his colleagues were associated. He lived up to and helped to spread the best traditions of physics as taught in Britain.

Dr. Wilson has left a wife and three sons.

J. W. BLAMEY

NEWS and VIEWS

Australian Atomic Energy Commission: Prof. C. N. Watson-Munro

The Australian Atomic Energy Commission has announced the appointment of Prof. C. N. Watson-Munro, professor of physics in Victoria University College, New Zealand, to the position of Chief of Research and Development. The Australian Government has already approved a programme of construction of a nuclear research reactor and research laboratories in New South Wales, and these will be the first objective of the scientific team to be built up under the direction of Prof. Watson-Munro. Prof. Watson-Munro, who is thirty-nine years of age, was born in New Zealand and educated at Victoria University College, Wellington. During 1936–39 he was employed by the New Zealand Department of Scientific and Industrial Research as a geophysicist; he published a paper on a reconnaissance magnetic survey of the New Zealand thermal regions (now being used for the production of heavy water) and one on a radioactive survey of New Zealand rocks and soils. In 1939 he transferred to radar work, and after a year in 1941 with the American radar team at the Massachusetts Institute of Technology, he became director of the New Zealand Radar Development Laboratory. In addition to meeting the needs of the New Zealand Armed Forces, this Laboratory supplied the Royal Navy with thirty radar sets and the U.S. Forces in the Pacific with ten mobile radar sets. Prof. Watson-Munro went into the Pacific war theatre with the sets supplied to the United States and was given the honorary rank of major.

In mid-1944, Prof. Watson-Munro led a group of New Zealand scientists sent to join the British–Canadian group of atomic energy workers in Montreal and at Chalk River. He took a leading part in the design and construction of the first Canadian heavy-water pile (ZEEP) and was responsible for the control equipment. In 1945 Prof. Watson-Munro went to England and was in charge of the design and construction of the first pile in the United Kingdom (GLEEP). He returned to New Zealand in 1948 to take over the position of deputy secretary of the Department of Scientific and Industrial Research in charge of all the physical, geophysical and engineering activities of that Department. He was also scientific adviser to the Armed Forces and attended two meetings of the Commonwealth Defence Scientific Advisory Committee. He took up his present appointment to the chair of physics at Victoria University College in 1951.

Division of Fisheries, C.S.I.R.O., Australia: Dr. H. Thompson

Dr. Harold Thompson, the founder and for seventeen years the chief of the Division of Fisheries of the Commonwealth Scientific and Industrial Research Organization, Australia, is to retire shortly at the age of sixty-four. Dr. Thompson is a Scot, born in Aberdeen in 1890, and from 1920, after service in the army during the First World War, he was for ten years scientific adviser of the Fishery Board for Scotland, gaining a D.Sc. of the University of Aberdeen in 1927 for his work on the natural fluctuations in the stocks of haddock. In 1930 he became director of fishery research in Newfoundland, a post which he left six years later to take up his present appointment in Australia. Although the Second World War halted many of the advances which he had planned, Dr. Thompson gave valuable service during this period as comptroller of fisheries in the Department of War Organization of Industry. The programme of research and exploration was resumed in 1946 and has continued with much benefit to the Australian fisheries and world fisheries science. The Division has contributed considerably to the establishment and extension of the whale, tuna, crayfish and shark fisheries; it has shown the need to relax the fishing pressure on certain kinds of fish, while indicating others that might be used to take their place, and it has made considerable strides in the study of the movement and fertility of Australian sea-water masses on which all marine life depends. Dr. Thompson leaves behind him a large body of knowledge of Australian fisheries and a thriving Division to carry on his work.

Industrial Power from Nuclear Energy

A Friday Evening Discourse was delivered at the Royal Institution, London, on December 3 by Sir Christopher Hinton, deputy controller of atomic energy (production), Ministry of Supply, his subject being "Industrial Power from Nuclear Energy". In his address, Sir Christopher explained that, whereas in the burning of hydrocarbon fuels to obtain heat only the extra-nuclear electrons of the atoms are disturbed, the production of heat from atomic fuels involves nuclear transformations, the most easily performed such transformation being nuclear fission. The only naturally occurring element which can be induced to carry out a chain reaction, whereby neutrons emitted from the fission of a nucleus cause fission in further nuclei, is the 235 isotope of uranium, and this process is used in the atomic pile, in which most of the large quantity of energy evolved is in the form of heat. The uranium pile reaction forms the artificial element plutonium, which is bred by neutron irradiation of the uranium-238 isotope and subsequent radioactive decay, and is also fissionable. To effect a balance between the neutrons used for fission and the neutrons used for breeding plutonium, a moderator is used, which slows down the emitted fast neutrons, making them more readily available to carry out the fission process. The graphite-moderated air-cooled piles at Windscale are not designed to utilize the heat evolved, the waste heat being ejected up the stacks; but the graphite-moderated carbon dioxide-cooled piles at Calder Hall will produce heat of high enough grade to raise steam suitable for electricity generation. A further type of reactor, called a breeder reactor, is envisaged, which will use enriched fuel and fast neutrons and which, besides producing useful heat, may produce fissile material in excess of its fuel consumption. Although the estimated cost of nuclear electricity is some 50 per cent above the cost of electricity produced by the most modern power station, Sir Christopher considers that the real cost should fall as techniques improve and a reasonable price is quoted for the fissile material bred in the piles. Thus he envisages the future programme as consisting of a chain of thermal reactors producing plutonium as a by-product, followed by the use of this plutonium in the fast reactor or breeder pile.

University College, London: Restoration of War-damaged Buildings

On November 30 a celebration was held in University College, London, to mark the restoration of the original College buildings in the main quadrangle, which were destroyed by enemy action during 1940–41. The present visitor to the College will find it difficult to realize the degree of damage which was suffered, so remarkable is the recovery that has since been made. Nearly fifty thousand square feet were totally destroyed and another fifty thousand were almost completely gutted by fire. The destruction included all the historic buildings of the College and much else, including the Physics Laboratory and the Great Hall. Fortunately, the College has been able to extend its site between Gower Street and Gordon Square to an area of twelve acres, and this has already given opportunities for the beginning of long-delayed expansions. The first block of the new Physics Building, a handsome and effective series of laboratories, has been completed. Industry has contributed to a preliminary stage in the development of the Chemistry Department. The College authorities feel that the most pressing need of the moment is for a new Great Hall, since at present the only assembly room is the Gustave Tuck Theatre, which, though a beautiful building, houses less than two hundred. As the provost of the College, Dr. B. Ifor Evans, pointed out at the celebration, University College, London, has a very worthy place in the history of university education in Great Britain. Founded in 1828 as a centre for university instruction and research without any restrictions of race or religious faith, it has grown during the past century and a quarter in a notable way until its present student population is three thousand five hundred. Though the standing of a university institution does not rest solely on its architecture and setting, it is worthy of notice that the concepts of the College's original founders were matched by those of the architect, William Wilkins. He provided the College on its then newly acquired site in Gower Street with what John Summerson has described as its "tremendously grand portico raised on a great podium with steps"; to this were added later the Flaxman Gallery and the Donaldson Library, and a quadrangle was formed with the Slade School, the Bartlett School of Architecture and buildings for the Faculty of Arts and the School of Egyptology.

Advisory Committee on the Protection of Birds

The Home Secretary has appointed the following to be members of the Advisory Committee on the Protection of Birds for England and Wales: Sir A. Landsborough Thomson (*chairman*), Miss P. Barclay-Smith, Mr. P. E. Brown, Colonel R. S. Clarke, Mr. J. M. Craster, Mr. James Fisher, Mr. William Foster, Mr. Nigel Laing, Captain S. T. A. Livingstone-Learmonth, Mr. G. R. Mountfort, Mr. E. M. Nicholson, Major-General A. G. O'Carroll-Scott, Mr. Peter Scott and Mr. H. N. Southern. The Advisory Committee is appointed under the Protection of Birds Act, 1954, which came into force on December 1. The Act protects all wild birds, their nests and eggs, subject to specified exceptions; in particular, owners or occupiers of land may take action against specified harmful birds, and specified sporting birds may be shot outside the close season. The Act also restricts the sale and importation of birds and eggs and enables sanctuaries to be created.

Commonwealth Bursaries Scheme of the Royal Society and Nuffield Foundation: Awards

Awards under the Commonwealth Bursaries Scheme of the Royal Society and Nuffield Foundation have been made to the following: Dr. A. d'A. Bellairs, reader in anatomy, St. Mary's Hospital Medical School, London, to study material in South Africa during June–September 1955, in connexion with his work on the morphology and development of the vertebrate skull; Dr. D. A. Brown, senior lecturer in geology, Otago University, to study type-collections of the fossil Cyclostomatous and Cryptostomatous Polyzoa principally in London and Cambridge during 1955; Prof. S. N. De, professor of pathology, Nilratan Sircar Medical College, Calcutta, to study at University College Hospital Medical School, London, during June–September 1955, the mechanism of action of the cholera vibrio; Dr. A. J. Matty, lecturer in zoology, University of Nottingham, to visit Bermuda during March–September 1955 to extend his observations on the thyroid gland of bony fish; Dr. T. A. O'Donnell, lecturer in chemistry, University of Melbourne, to study inorganic fluorides at Cambridge during 1955; Dr. J. C. Smith, demonstrator and lecturer in chemistry, University of Oxford, to visit Pretoria and Melbourne during January–September 1955, to study methods of research on the chemistry of fats and waxes; Mr. W. Thomson, of the Rowett Research Institute, Aberdeenshire, to study sheep nutrition projects in Australia and New Zealand; and Prof. A. Wood, professor of geology, University College of Wales, Aberystwyth, to extend his researches, in Australia during January–May 1955, on the wall structure of the Foraminifera, to type and topotype material. This is the second group of awards under the scheme, which was instituted in 1953 to provide facilities for increasing the efficiency of scientists of proved ability by enabling them to pursue research, learn techniques or follow other forms of study in natural science in countries other than their own in the British Commonwealth.

Central Glass and Ceramic Research Institute, India: New Bulletin

The Central Glass and Ceramic Research Institute, which was opened in Calcutta in 1950, has now issued its first quarterly *Bulletin*, "devoted to the cause of the advancement of glass, ceramic and allied science and industries" (1, No. 1; August 1954; pp. 44; annual subscription Rs. 6 or 12*s.*; single issues Rs. 2 or 4*s.*). It is stated that each *Bulletin* will include a discussion of important current topics relating to the ceramic industry, and in India, as in the United States, the ceramic industry is taken to include the manufacture of glass and vitreous enamels in addition to pottery, clay building materials and refractories to which the term is confined in Britain and Western Europe generally. The *Bulletin* will also contain technical articles, manufacturers' experience, articles on production and quality control, new developments, answers to inquiries, trade statistics, news and reviews, books and abstracts. In this first issue there are two technical articles. The first deals with glass containers suitable for distilled water and is by Atma Ram (director of the Institute), S. P. Krishnaswamy, P. Roy and Sudhir Sen; original work is reported in a well-written manner, and definite recommendations are made for the benefit of the Indian glass manufacturer. The second technical article is on saggars for use in the pottery industry, and is an abridgment of a paper previously published in the *Journal of Scientific and Industrial Research* [India]. The *Bulletin* is well produced, and provides a good illustration of the change in outlook that is taking place in India at the present time.

Insects and the Diseases of Conifers in New Zealand

In "New Zealand Forest Research Notes" (1, No. 8; October 1953. Wellington: Government Printer), the forest pathologist, G. B. Rawlings, discusses insects of *Pinus radiata* forests in New Zealand, giving a list of all the insects known to have any connexion with *Pinus radiata* forests in the country. *P. radiata* is an introduced exotic species of conifer and has been widely planted. Introduced exotics, whether forest or agricultural, planted as pure crops on a large scale in many parts of the world, have proved to be very subject to attack by fungus or insect pests, some of which are of local origin, and the others introduced. With the presence of extensive pure crops in the countryside, the danger becomes greatly aggravated, and heavy losses may be entailed by the dangerous attempts to provide within short periods rapid-growing crops to supply either an existing demand or to obtain high financial returns. There are countries where the introduction of exotics (New Zealand is an instance) to increase the area of forests in the country is fully justified. The Forest Department of New Zealand commenced planting conifer exotics early in the present century. Private companies took up the work, with the result that many large areas of exotic conifers, such as *P. radiata*, for example, exist in pure blocks. Coleoptera and Lepidoptera (for example, *Tortrix*) may prove exceptionally dangerous, attacks once started spreading with great rapidity and getting the upper hand. An annotated list has been compiled with the main objective of recording all insects known to have any connexion with *P. radiata* forests in New Zealand. As the author writes, it is important for the forest officer to understand at least the rudiments of the life-histories of the insects, because species thought to be unimportant may suddenly become significant under certain conditions. It is not only in Europe where the forest officer has had to face sudden outbreaks of this type; the more dangerous are new countries where forestry conditions are not so well understood, and unknown and untried exotics have been introduced.

Society for the Promotion of Nature Reserves: Handbook for 1954

The handbook for 1954 of the Society for the Promotion of Nature Reserves (pp. 64+8 plates; from the Society, c/o British Museum (Natural History), London, 1954; 5*s*.) includes the annual report and financial statement for the year ended March 31, 1954. The lease of Wood Walton Fen to the Nature Conservancy has greatly reduced the Society's outgoings, and its membership has increased. Further, it is no longer necessary to keep in being the many regional investigation committees set up some years ago, some of which have been converted into committees of local natural history societies or trusts. At the annual meeting of the Council on July 1, 1954, the president, Lord Hurcomb, emphasized the ability of the Society to stimulate public interest in, and support for, the Nature Conservancy and said that the Society also endeavours to extend such interest and support to the protection of flora and fauna and scenic beauty elsewhere, in close association with the International Union for the Protection of Nature and the British Co-ordinating Committee for Nature Conservation. The Society is also able and ready to give financial support for the preservation of areas which may not on scientific grounds justify in present circumstances the limited funds of the Nature Conservancy but need and merit protection before they are lost for ever. Specific examples of how this has been done in Lincolnshire are given in a lecture on the Lincolnshire Naturalists' Trust, delivered by Mr. A. E. Smith at the annual meeting of the Society on July 1 and which is published in the handbook. The handbook also includes an illustrated account, by Mr. E. J. Mason, of the island of Steep Holm, in the Bristol Channel, and the Steep Holm Trust; a note by Mr. F. H. W. Green on the progress of the Nature Conservancy in the acquisition and safeguarding of sites of special scientific interest; a note on the Nature Protection Conference at Beirut; and an illustrated account, by Dr. L. Machwa, of experiments which the Lower Austrian Nature Protection authorities have made with propaganda posters on Nature protection.

Exhibition of Historic Astronomical Books

The exhibition of historic astronomical books which is currently being held at the Science Museum, London (see *Nature*, August 14, p. 298), is one of a series designed to illustrate science and technology and their histories by means of the written word or pictorial representation, as distinct from the actual apparatus or products. In addition to those in the Science Museum's own possession, the Royal Astronomical Society has lent many valuable books. The catalogue of the exhibition (Museum Book Exhibition No. 3: Historic Astronomical Books. By G. H. Adams and H. R. Calvert. Pp. 29. London: H.M.S.O., 1954. 2*s*. net) contains the titles of seventy-five books, the first of which is Newton's "Philosophiæ Naturalis Principia Mathematica" (1687) and the last Struve's "Stellarum Duplicium et Multiplicium Mensuræ Micrometricæ" (1837). No books published within the past hundred years have been included, for which reason modern works (such as those of Einstein, Eddington, Jeans and Lockyer) which rank as historic books are not mentioned. When books are published in a language other than English, a short title, sufficient for identification, is first given in the original language, followed by an English translation of some or all of the original title. An alphabetical index of authors appears at the end of the catalogue.

Announcements

Prof. P. A. M. Dirac, Lucasian professor of mathematics in the University of Cambridge, has been granted leave of absence for the current academic year by the University. Prof. Dirac is now visiting the Tata Institute of Fundamental Research at Bombay, where he is staying until early in 1955, after which he is proceeding via Japan and Vancouver to the United States for a short visit, and then to the National Research Council of Canada at Ottawa.

Erratum. In the article entitled "Differentiation of Growing and Non-growing Bacteria by a Staining Technique" in *Nature* of November 13, on p. 921, col. 2, line 35, the time of staining should read "30–60 sec.", not "30–60 min." as printed.

NEW NATURE RESERVES IN ENGLAND AND WALES

THREE new nature reserves in England and one in Wales were declared by the Nature Conservancy on November 24, and a further two acres were added to the Bridgwater Bay Nature Reserve, by the declaration of Steart Island, off the mouth of the River Parret, on the termination of an existing tenancy. Steart Island, which is separated from the mainland at high tide by half a mile of water, is the roosting-place for hundreds of geese, mainly white-fronted geese, and is the only known area in Britain where moulting shelduck gather each summer; for this reason it is hoped to keep the island entirely undisturbed.

Cwm Idwal Nature Reserve, the first Welsh nature reserve, and the first to be declared in a national park, is a natural amphitheatre rising to above 3,200 ft. in the heart of Snowdonia National Park, about four miles north of Snowdon, and this 984-acre area has been leased to the Conservancy by the National Trust, subject to existing farm tenancies. Its wide variety of volcanic rocks carries an interesting flora, dating from immediately after or even before the latest Ice Age. Green spleenwort, lloydia, purple saxifrage, water lobelia and quillwort are found there. The University College of North Wales, Bangor, will continue to use Cwm Idwal for botanical, research and teaching purposes, and the Conservancy's own work will probably include work on the inter-relation of vegetation and soils and the effect of grazing on some of the important plant communities. Climbers and mountaineers accustomed to visit the area will find no change in access; but formal applications must be made for research in the Reserve or for collecting specimens of animals or plants.

Blelham Bog Nature Reserve, lying on the north-western edge of Blelham Tarn, three and a half miles south-west of Ambleside, is a rare example of the development of sphagnum bog from wet wild woodland, very little of which now remains. The vegetation is mainly *Sphagnum–Molinia–Myrica* bog with unusual species such as great sundew, white beak-sedge and downy sedge and many of the bog mosses characteristic of this type of transitional environment. Of the caddis flies found there, *Limnophilus xanthodes* McLachlan, extremely rare elsewhere in the Lake District, is fairly abundant. Access will not be restricted; but permits will be required for the collection of animals or plants in the Reserve.

The chief interest of Hartland Moor Nature Reserve, which covers 178 acres close to the Conservancy's Research Station at Furzebrook and is about one and a half miles south-east of Wareham, Dorset, is the domination of the vegetation in parts by the rare Dorset heath (*Erica ciliaris*). Other rare bog plants are also found in the Reserve, and there are interesting local variations in the flora, probably related to differences in the drainage. Public access will not at present be restricted; but permits will be required for collecting.

Arne Nature Reserve is a small section of Big Wood, about two and a half miles east of Wareham, and is one of the two known places in the country which show the natural transition from dry woodland to salt marsh—a brackish tidal condition. Parts of the wood probably represent the remains of the primitive broad-leaved forest; but it also contains such interesting features as the rare royal fern (*Osmunda regalis*) in a natural habitat. There are valuable potentialities for scientific research, notably into the effects of water-logging and the transition between salt marsh and either woodland or heathland. Cord grass (*Spartina townsendii*) is present on the seaward fringe, where studies will be linked to the experiments on coastal vegetation at Bridgwater Bay. Permission to visit will be required, and also authority to undertake research or collect specimens.

INSTITUTE OF PERSONNEL MANAGEMENT

ANNUAL CONFERENCE

AT the forty-first annual conference of the Institute of Personnel Management, which was held at Harrogate during October 8–10, the opening speaker was Admiral Sir Denis Boyd, principal of Ashridge College. On the general theme of leadership, Sir Denis said that he is convinced that people cannot be trained in its most important aspects. In leadership there is a combination of technique and personality; the technique can and should be taught to everyone in any kind of authority, the crux of the technique being administration. Problems are not solved by inspired decisions, he continued, but by constant thought, intelligent anticipation, waiting, foresight, patience and organization—that is, administration. The delegation of responsibility is the key to wise administration. Among the attributes of leaders are enthusiasm, austerity, sincerity, courage and humility.

Sir Miles Thomas, chairman of the British Overseas Airways Corporation, discussed the changing pattern of British industrial management. First, he said, there was the development of specialized management—the breakdown of management into a variety of techniques. In the early days of British industry and up to the early years of the twentieth century, the 'boss' of the firm was the owner. He alone carried the risk of losses and reaped the reward of profit; it was his financial credit, and that of the bank, which determined how easily he could get fresh capital for expansion. The owner naturally had the undisputed right to 'hire and fire' when and how he liked and, within broad limits, to pay just as much or as little regard as he felt inclined to working conditions or to wages.

Gradually, the demands of technical development, commercial competition and, above all, of the pressing need to raise more capital to keep pace with the growing scale of operations and expansion, produced two changes almost simultaneously. First, the owner found that, to obtain the necessary capital, he was compelled to turn the concern into a joint stock company, with ownership in the hands of the stockholders, while he himself was appointed managing director. Secondly, the scale of the managerial problem presented by the growth in size and complexity of the business meant that no longer could he, even as managing director, deal with every side of the business himself. From this situation there emerged the manager as a person and a position to be respected. He became the final authority from whom originated instructions on policy and on their execution. Inevitably there grew up specialists in the various branches of management. Production and sales were the first to be clearly separated, and these were followed by various dichotomies and drafting processes until, by the end of the First World War, the familiar pattern of production, sales, finance, research, planning and buying was becoming the general rule.

This division of labour at the highest level called at once for a better quality of general management than had hitherto been required. The second feature of the industrial and commercial management scene was the changing balance of emphasis and importance between the several elements of specialist management. The period immediately after the First World War was mainly one of developing the selling power of British goods. Consumers had to be found and shown that their interest was best served by buying a particular line of goods. Above all, the sales manager had to have sufficient authority to see to it that the technical or production departments produced the goods he wanted. In response to the developing authority of the sales department, powerful incentive was also provided for the development of research in industry, both of a fundamental nature and in the various technological processes. This era of the growing power of sales management was succeeded by the development of financial management. The growing complexity of the financial structure of the big joint stock company, the stringent requirements of the various Company Acts and the ever-pressing pressure of the Inland Revenue, produced a demand for experts in this field to be represented in the executive management of most concerns of any size.

The end of the Second World War saw the emergence into a new importance of the latest development of specialized management—personnel. Due to the immensely significant social and economic changes in the years immediately following the Second World War, there was at once an overwhelming and critical demand from men and women in industry to be regarded each as individuals with rights and responsibilities. This meant that the element of executive management which should be the last which any managing director wishes to delegate became rapidly of vast and specialized importance in the form of a personnel or employee relations department. This further specialization of management into personnel or staff management shows the emergence of the conception of the responsibility of industry to society.

There seem to be three main ways in which developing economic and social patterns have emphasized the importance of personnel management since the War. First, the significance of the individual has been underlined in a purely practical way. It has been generally appreciated that the application of large sums of money and intense research effort by the best technical brains available to securing and devising exactly the right piece of equipment to perform a certain job can be rendered largely nugatory if the men and women who operate it are so ill-suited to the task that they do not get the best out of it. Secondly, society's demand for equality and justice generally bears directly on the personnel manager's job. In this context there is also the vastly important field of relations with the trade unions. Thirdly, the personnel function has been heavily emphasized by the vast range of problems involved in getting more out of a group of people than the sum of their individual efforts.

Mr. C. J. Geddes, president of the Trades Union Congress, considered the role of trade unions in the future. During and after the Second World War, he said, there has been a profound change in the attitude of the trade union movement, and an attempt is being made to avoid a clash with employers and management. In the immediately foreseeable future, however, the fundamental purpose of the trade union movement will not change, nor will officials cease to strive in every possible way to get every farthing they can for their members. They will not abandon their right to use force. The driving spirit of the trade union movement does not rest with the leader, nor is the policy determined by the leader, but by the individual member.

There has been no fundamental change in the outlook, purpose or objective of the trade union movement, continued Mr. Geddes. The trade union leader is no longer a bitter enemy of the employer; but he is not yet his friend. There is not the slightest hope in the foreseeable future of the trade union movement agreeing to a national wages policy, not only because of the extreme difficulty of trying to devise one, but also because the trade union movement would largely sacrifice its purpose if it did so.

Will the trade unions demand a greater share in the management of industry? Mr. Geddes thinks they will, and it may be one of the major differences between the trade union movement and the employers in the immediate future. This does not mean that trade unions are going to demand that they must have joint control, but that they should become more and more equal with management and have much more information about the operation of particular industries.

Looking at the industrial scene, Mr. J. B. Priestley, the author, declared that there is a danger that our highly industrialized urban life may rob men of so many of the primary satisfactions that, in their sense of frustration and resentment, they may create a society so violent that it will explode in our faces. There are certain things men and women want: the English love to use their energy intermittently—they do not want to use the same amount every day, or to be harnessed to something keeping a regular tempo. He hoped that, as industry develops, it will be possible to make machines gear themselves to men and not men to machines. Everything—even employment and hours of work—is too regular: people do the same dullish job too long. We are in danger of creating a highly industrialized society which has lost all feeling for the soul or for any notion of man as a spiritual being—a society that might imitate the cruelties of ancient Rome to release its feelings of frustration.

The second danger in this industrial age, continued Mr. Priestley, is that the future organization of human affairs may deteriorate because we are not producing good human beings to take charge of them. We spend thousands of pounds on education, but to what end? It is no good pouring money into a school unless we are going to spend money and take time and trouble over the street outside the school; environment will always defeat education. Looking at Britain as an environment, it is important to think of the forces playing on the people personnel managers have to handle: we should think of the way such people are not encouraged to think for themselves at all. The reason why young working people are not showing any sort of enterprise is the recent creation of a complete mass working-class culture.

To keep industry going, we need a fair proportion of young men and women who are individuals with initiative, who think for themselves and have some sense of mental and spiritual development. We should do everything to make that possible, because we do not want our great-grandchildren to be living in an ant-heap and to be indistinguishable from the robots they might be making to serve them.

A valuable feature of the Conference was a number of 'brains trusts' sessions at which experienced personnel officers answered questions on such varied themes as work and health; management training courses; wage differentials; and discipline and full employment. T. H. Hawkins

NUTRITION AND THE ALIMENTARY TRACT IN MAN

THE Scottish Group of the Nutrition Society held a conference in Dundee on October 23 on "Disorders of the Alimentary Tract and their Nutritional Effects". In discussing disorders of fat absorption, Dr. J. M. French (Department of Pharmacology, University of Birmingham) said that fat absorption is defective in many clinical conditions, often as part of a generalized absorptive defect. Assessment of the degree of defect of fat absorption cannot be made by microscopic examination or percentage fat in the wet or dry fæces, and some type of fat balance must be employed. A continuous study of fat absorption, using the rapid daily fatty-acid estimation of Kamer, Huinink and Weijers, is essential if results of treatment or other procedures are to be assessed in a reasonable period of time. The accumulation of data with the same rapidity by the use of balances at intervals is precluded by the great day-to-day variability shown by subjects with defective fat absorption. The continuous method is especially applicable to such problems as the effective replacement therapy of pancreatic insufficiency with various types of pancreatic extract.

Wheat and rye gluten as a causative factor in cœliac disease, originally demonstrated in Holland by Dicke, Weijers and Kamer, has been amply confirmed in Britain. Although many adult cases of idiopathic steatorrhœa have a history of cœliac disease in childhood, the response of the adult to a wheat gluten-free diet is disappointing. Five cases of complete recovery have been recorded, however, suggesting that it is the basic factor. Failures may be due to superimposed vitamin deficiency, sensitivity to factors other than wheat and rye protein, or increased bacterial growth in the rich medium provided by the slow absorption of food. Evidence for the latter in tropical sprue has been provided by the use of intestinal chemotherapy.

Specific infection, dietary deficiency and tropical conditions are unsatisfactory as theories for the primary cause of tropical sprue. Considerable evidence has been accumulated to suggest that oxidative rancidity of unsaturated cooking oils may start tropical sprue, the intestine being irritated by some chemical constituent. This evidence is provided by the fact that sprue is rare in tropical countries such as Africa where saturated fats are consumed, but common in India and the Far East where cooking oils, such as rapeseed, sesame and mustard oil, are consumed. The high incidence in India among European and Indian troops during 1942–45 coincided with a change in dietary fat intake both in quantity and type, which would be in conformity with this theory. Experimental support is given by work in rats, which rapidly develop diarrhœa, steatorrhœa, emaciation, anæmia and death, if fed on rancid unsaturated fats.

Dr. R. H. Girdwood (Department of Medicine, University of Edinburgh) spoke on the occurrence of vitamin-deficiency conditions related to disorders of the alimentary tract. Conditions that interfere with vitamin intake include destruction of the area of the stomach that secretes the 'intrinsic factor'; rapid passage of vitamins particularly as a result of fistulæ; stagnant or blind loops of small intestine; and disease of the intestine or mesenteric glands.

Clinical impressions of specific vitamin deficiencies are misleading, and biochemical loading tests are not very satisfactory. Nevertheless, a differential urinary folic-acid excretion test is of diagnostic value in showing poor absorption of folic acid in conditions such as idiopathic steatorrhœa. After total or partial gastrectomy operations, or even after a gastro-enterostomy, megaloblastic anæmia may develop; steatorrhœa may also occur, but serum vitamin B_{12} tests show that the deficiency is of vitamin B_{12} and not folic acid. Where an anæmia is the result of a stagnant loop, it may not respond to any vitamin therapy, and presumably toxins are being absorbed from the loop.

The interpretation of studies of vitamin balance is complicated by the metabolism of the microbes found in the alimentary tract. Strains have been demonstrated both to synthesize and to absorb such vitamins as cyanocobalamine; their net influence is still uncertain, and may vary in different conditions.

Dr. D. A. K. Black (Department of Medicine, Royal Infirmary, Manchester) discussed the effects of alimentary disease in mineral metabolism. In general, chronic alimentary disease leads to mineral malnutrition as a result of deprivation and malabsorption of food minerals, while in acute catastrophes the loss of alimentary secretions is the predominant feature. Disease of the alimentary tract is the principal cause of potassium depletion, and has been demonstrated in pyloric stenosis, gastro-enteritis, ulcerative colitis and steatorrhœa and even as a consequence of excessive use of laxatives. This may result from deprivation of food intake, which is usually of the order of 100 m.equiv. daily, increased loss in the stools, and loss by vomiting. The potassium content of alimentary secretions is about one-tenth of the sodium content, so that in acute disturbances sodium depletion predominates; nevertheless, significant loss of potassium may occur, in chronic disease partly because colonic absorption of potassium is much less complete than that of sodium and partly because renal loss of potassium is greater than that of sodium when there are comparable body deficits of the two ions. The catabolic response to surgery leads to further loss. When potassium has to be given by intravenous injection, it should not be of greater concentration than 40 m.equiv./l.

It is generally agreed that fæcal excretion of iron represents unabsorbed iron. Impaired absorption has been observed in the steatorrhœa syndrome even in patients with neither achlorhydria nor overt diarrhœa. Moderate impairment can often be countered by oral administration of iron salts, but severe cases require intravenous injections.

The pathogenesis of osteomalacia in association with steatorrhœa is complicated. First, the presence of excessive fatty acid in the bowel leads to the formation of calcium soaps the calcium of which is not available for absorption; this can be improved by a low fat diet. Also, vitamin D is poorly absorbed, and further improvement of absorption can be induced by parenteral vitamin D or very large doses by mouth. The prolonged treatment of peptic ulceration with large amounts of milk and alkalis can lead to calcium intoxication and, in severe cases, renal failure associated with calcification of the renal tubules.

Prof. R. B. Hunter (Department of Pharmacology and Therapeutics, Queen's College, Dundee) reviewed the method of clinical presentation of fifteen cases of idiopathic steatorrhœa recently studied in the Therapeutics Unit, Maryfield Hospital, Dundee. In less than half these cases was diarrhœa the predominant symptom though all complained of tiredness and loss of appetite. The patients learned to control their own diarrhœa by reducing their fat intake. Cases of apparent iron-deficiency anæmia with malabsorption of fat, macrocytic anæmia or megaloblastic anæmias responding to folic acid were shown. Two cases of extreme calcium deficiency were considered in detail, and the problems of finding an effective means of calcium replacement in the face of impaired alimentary absorption were considered.

Food allergy was discussed by Dr. J. A. Milne (Department of Pathology, University of Glasgow), who said that, in order to discuss food allergy, it is necessary to consider first certain basic facts concerning allergic reactions and the immunological basis of allergy. When an antigen first enters the body, it stimulates the formation of specific antibodies. Some of these antibodies tend to persist in their free state in the circulating blood (circulating antibodies), and this would appear to constitute immunity. Others become incorporated into the substance of cells and become 'sessile' antibodies or fixed antibodies, and so the allergic state is established. Why some people develop sessile antibodies and thus become hypersensitive is completely unknown. Various sites may be affected—for example, the nasal mucosa and conjunctiva, the skin, etc.—and tissues so affected are known as 'shock organs'. What actually takes place when a tissue containing sessile antibodies comes in contact with its specific antigen is not known. There is considerable experimental and clinical evidence to suggest that histamine or a closely related substance is released.

Proof of the existence of food allergy depends on the demonstration of a cause-and-effect relationship between the ingestion of a given food and the production or accentuation of the patient's symptoms. The use of skin tests, either by the scratch or intradermal technique using concentrated extracts of foods, may occasionally be of help, although on the whole the results tend to be disappointing. Fortunately, many persons with food allergy, as well as having sessile antibodies, have some circulating antibodies. This allows the use of the Prausnitz–Kustner reaction for diagnostic purposes.

The ideal treatment of food allergy is, of course, the avoidance of the offending food, if this be known. The most widely used drugs at present are the antihistamines, and the results with them other than in papular urticaria in children are rather disappointing. Cortisone and adrenocorticotrophic hormone have been used with good results, although the symptoms tend to recur with increased severity once the drug is withdrawn.

FERROELECTRIC PROPERTIES OF SINGLE CRYSTALS

A COLLOQUIUM on the ferroelectric properties of single crystals, arranged by the Radio Components Research and Development Committee, was held at the Signals Research and Development Establishment, Christchurch, Hants, during September 16–17. Some sixty scientists attended in response to invitations, the Armed Services establishments, the universities and industry being represented in fairly equal numbers. The Bell Telephone Laboratories, New Jersey, which had supplied a number of large crystals for investigation by British workers, were represented by Dr. B. T. Matthias, who has achieved international reputation in this field. W. Bol and S. Duinker, representing Philips, Eindhoven, were also present.

The first paper, presented by C. F. Oxbrow (Christchurch), was prefaced with a short account of the fundamentals of the structure of barium titanate and their relation to electrical properties. Representative figures measured at Christchurch for the Bell crystals were saturation polarization, 22·5 μcoulombs/cm.^{2}; hysteresis loop area, 1·4 × 10^{-3} joules/cm.^{2}; permittivity along *c*-axis, 300 at room temperature. The optical properties of the Bell crystals were then described. These crystals, plates 1 × 1 × 0·02 cm., had a large area with the optic axis normal to the plate but were crossed by occasional laminar wedges of twinned material inclined at 45° to the plate. Seen by polarized light, these wedges produced broad interference bands on a uniform background. These twin domains were removed by the application of an electric field. A colour film of this type of domain change was shown, and inferences drawn on domain magnitude and growth. The paper concluded with a description of measurements to determine the refractive index n_0 accurately, the methods described being particularly applicable to these crystals. A modification of Chaulnes's method led to a value $n_0 = 2·49$.

P. Parsons (General Post Office Research Laboratories) exhibited photographs of the Bell crystals showing the crinkling due to the laminar domains as seen by ordinary light, the changes brought about by heating to the Curie point, and the re-establishment of the original domains by an electric field. Electrical measurements were also described. The charge/voltage hysteresis loop was particularly square; the coercive field was of the order of 1·1 kV./cm. at 50 c./s. but only 500 V./cm. for direct current; in the region of the Curie temperature an electric field gave well-defined double or constricted loops. The behaviour of domain walls is evidently dependent upon the rate of change of field because measurements showed a sharp peak in the differential permittivity at a bias field equal to the coercive field. The frequency of the small measuring field was 100 kc./s. and that of the large bias field 50 c./s. These results contrast with the substantially field-independent value measured at Christchurch using d.c. bias.

D. Gibbs (University of Bristol) discussed domain changes. 90° walls which separate regions with polar axes at 90° are easily observed. 180° walls separate antiparallel regions and are observable by polarized light only when additional cross-stress is applied. 180° wall change, equivalent to domain reversal, takes place by nucleation and growth of spike-like domains in the direction of an applied field[1]. Both 90° and 180° wall changes are possible in single crystals. In ceramics the electrical stress set up normally precludes 180° wall changes, and a parabolic (x, D) relation $x = kD^2$ due to 90° wall movements is obtained. Measurements at Bristol of electric displacement D and thickness-strain x produced values of k up to 5×10^{-8} e.s.u. In very pure barium titanate ceramic a flattening of the (x, D) curve at the vertex could be explained by 180° wall changes occurring at low field. In this pure ceramic a kink appeared in the side of the familiar D/E hysteresis loop if the applied a.c. field was suddenly increased. The kink grew out at a rate dependent on temperature, and this could be evidence of the nucleation period involved in 180° wall changes.

Problems which have arisen in growing single crystals of barium titanate were discussed by J. Herbert (Plessey, Ltd.). A pure intimately mixed raw material was made by incinerating barium titanium oxalate. The Verneuil oxy-hydrogen blow-torch method was tried. Lack of success in growing large tetragonal crystals was due to the growth of crystals in the hexagonal habit. To obtain barium titanate in the tetragonal form by crystallization from a melt of titanium dioxide and barium oxide, it was necessary to use a flux. Barium chloride yielded nearly perfect crystals of barium titanate in the form of thin plates, but the yield was small. Potassium fluoride yielded crystals in the form of 'butterflies', pairs of triangular plates joined along one edge. A lively discussion followed between Dr. Matthias (Bell Laboratories), Mr. Rhodes (Standard Telecommunications Laboratories) and Mr. Herbert on the merits of the potassium fluoride method as used by J. P. Remeika[2] in growing the excellent crystals described by the earlier speakers. Dr. Matthias also said that Mr. Remeika had succeeded in converting by heat treatment the hexagonal into the cubic form and vice versa. Evidently the fluoride method should be used for obtaining flat plates, while other methods such as the Verneuil might provide shapes suitable for piezoelectric investigations.

D. Campbell (Plessey, Ltd.) described major differences between crystals grown from barium chloride and potassium fluoride solvents. The potassium fluoride crystals had a surface strain layer which gave a square-net pattern under polarized light; the pattern disappeared and then returned when the crystals were heated and cooled through the Curie temperature (120° C.). The strain layer was etched away by phosphoric acid. Above the Curie temperature the optical activity of the chloride melt crystals completely disappeared, whereas some activity persisted in the case of those from fluoride melt. X-ray photographs indicated the normal contraction of c/a ratio with temperature in agreement with observed birefringent changes for the 'chloride' crystals. The 'fluoride' crystals had very complex photographs at 85° C. Hysteresis loops were directly dependent on complexity of structure. The American fluoride-melt crystals had ferroelectric constants agreeing with those of the chloride-melt crystals although the hysteresis loops were much more square.

In summarizing his work on sodium niobate, Dr. L. E. Cross (University of Leeds) reviewed previous work and anomalies between optical, electrical and X-ray measurements examined. His method of preparation and selection of single crystals for examination was described. Details were given of measurements of birefringence, type and arrangement of internal twins and dielectric constants over the temperature range −195° C. to +650° C. Owing to excessive conduction, observations of the effect of high electric field were given for the range −190° C. to +20° C. only. Summarizing, above 340° C. sodium niobate was not tetragonal but had orthorhombic symmetry, and there were two further changes before it became cubic at 638° C. The anti-ferroelectric structure at room temperature was confirmed, and there was some evidence of an additional ferroelectric polarization at low temperatures.

Two further papers on theoretical aspects of ferroelectricity were contributed by Drs. H. F. Kay and A. Devonshire (both of the University of Bristol). Dr. Kay dealt with the crystal structure of perovskite materials, with emphasis on $(Cd,Ca,Sr,Ba)TiO_3$, $(Li,K,Na)NbO_3$ and $(Li,K,Na)TaO_3$. Present knowledge is still only sufficient to indicate which materials are likely to be electrically unstable and the probable effects of substitutional replacements. The concept of ionic packing determines the probable type and magnitude of distortion at room temperature in the TiO_6 octahedra characteristic of the perovskite structure. These factors can be correlated to the probable type and frequency of twinning. In barium titanate the barium ion is so large that the structure can be broken down into sheet-like Ti-O groups, accounting for the polar character. The process is essentially ionic, since recent electrical measurements of saturation polarization agree with the value obtained from X-ray data on ionic shifts. The change in character of the distortion was traced as ion size was reduced progressively from barium through strontium until finally a tetrahedron-like formation was met in non-ferroelectric cadmium titanate. The substitution of lead produced anomalies which can be partially understood. Similar arguments are in general applicable to the alkali niobates and tantalates. In sodium niobate the structure is complex, and the unit cell quadrupled. Nevertheless, its field-dependent ferroelectric behaviour can be explained.

Discussing atomic models, Dr. Devonshire said that, while physical measurements are usually conducted at constant pressure, the constants immediately derived from atomic models are those for constant volume. For the perovskites the distinction is drastic. Thus in barium titanate the ferroelectric transition at constant pressure is discontinuous, a first-order transition, while calculations indicate that at constant volume the change would probably be second order. In contrast to ferromagnetics, the dipole interaction in ferroelectrics is long-range. Various types of model were considered by Dr. Devonshire: the type appropriate to potassium dihydrogen phosphate, in which an ion can take up two or more equilibrium positions; and that appropriate to barium titanate where the field in which the ion moves is anharmonic. The former gives with temperature a rapid change of χ, the reciprocal susceptibility or dielectric stiffness, while the latter gives a small change. Thus, the respective values of $\partial\chi/\partial T$ are 28·0 and 0·75. The Mason model for Rochelle salt was also considered. Here two sets of ions moving in unsymmetrical fields provide, as required for this material, a polar state stable only between two temperatures. A model for anti-ferro-electricity might be built on similar lines.

Both sessions were terminated by general discussions, Dr. Matthias presiding on the first day and C. G. Garton (Electrical Research Association) on the second. The subjects at both discussions were the practical uses of barium titanate crystals, with particular emphasis on digital storage. The fundamentals of storage and methods of investigation were described. Dr. Matthias said that the Bell Laboratories are concentrating on investigations into the serious deterioration in polarization properties caused by the protracted application of unbalanced pulse trains. Mr. Oxbrow said the deterioration is amplitude-dependent and is serious only if pulse amplitudes of the order of the coercive field are used. I. Carter (Ferranti, Ltd.) reported that, after the decay, a low-frequency property, sufficient storage effect exists for high-speed operation. Also, the initial state can be restored by periodic application of a small d.c. bias. Dr. A. Robinson (Ferranti, Ltd.) compared the merits of dielectric and ferrite storage. The advantages of barium titanate storage are compactness and a more convenient impedance for use in valve circuitry. Ferrite storage has the advantages of a more advanced state of development and, although offset by clumsiness, the versatility of variable 'turns-ratio' coupling. Very recent experiments with barium titanate indicate polarization times as low as 0·5 μsec., so that it might permit greater speeds of operation than ferrite.

A. C. Lynch (General Post Office) said that confirmation by Merz[1] that 180° walls do not move laterally has removed the fear that the polarizations of adjacent crystal areas might interfere. B. de Ferranti (General Electric Co., Ltd.) suggested that the non-linear characteristic of barium titanate capacitance versus field should be used in a dielectric amplifier. This would necessitate further investigation of noise in ceramics and single crystals. I. Ross (Services Electronics Research Laboratory) mentioned a possible use in infra-red switching, provided that the change in the 45° laminar domains is adequately fast. Measurements have been made of the infra-red transmission of one of the Bell crystals.

SHIFT WORK IN INDUSTRY

THE Institute of Personnel Management (2–10 Hill Street, London, W.1) has issued a broadsheet surveying the issues which affect the application of shift systems in industry. The broadsheet has been prepared by F. P. Cook, of Courtaulds, Ltd., but is based upon information obtained from a large number of different industries.

Among the conclusions brought out in the survey is that the economic advantages of shift work are greatest where capital charges and overheads are high in relation to labour costs. The greater the proportion of the total cost of production that is occupied by labour costs, the less the economic advantages of shift work become. When shift work is first introduced in a discontinuous process where employment has previously been on day work, the double-day shift system is probably the most advantageous for all concerned—for management because it is a second shift which offers the greatest alleviation to fixed charges, and for employees because the physical and social disadvantages are much less than those of shift systems which involve night work. The appeal of shift work to employees depends largely on how attractive it is made financially. Although it is only one factor, shift work can prove a sound economic way of meeting the natural urge towards shorter hours of work and higher earnings.

Quite apart from the ballot which is usually required by law before women and young persons can be employed on double day-shift work, the investigations show that full explanation and consultation are needed before any successful shift system can be introduced. Of all shift systems, those involving night work are most likely to have a deleterious effect on health; this is especially applicable to systems which involve permanent night work. Any unfortunate effects will vary with individuals, the nature and hours of their work, and their habits outside the factory, so that it would be hard to establish a general rule, even if more evidence were available. For most employees, shift work involves a balancing of material gain against social loss; thus, in pursuing the possible economic advantages of the extension of shift work, which can only be a gradual process, those in authority must take the possible social drawbacks into account.

Mr. Cook concludes that one of the temptations of these complicated times is to over-simplify, and this is typified by the search for the single solution to any problem. In personnel management, recent years have seen the fashionable development of joint consultation, job evaluation, communications, financial incentives, financial enlightenment, merit rating of management development, and work study. Despite the creation of much pseudo-technical supporting jargon, not one of these is a cure-all by itself, and together they can be no more than further aids to the vastly complicated business of modern industrial management. The extension of shift work will not alone revive the fortunes of a nation or concern; but, in the right circumstances, it can help.

FORESTRY COMMISSION

REPORT FOR THE YEAR 1952–53

IN the operations of the Forestry Commission during the year 1952–53*, economy in spending was a guiding factor in deciding the programme of work. In order to carry out the expanding programme of planting and thinnings in the young plantations with the funds available, it was necessary to postpone work such as building new houses and new roads. Many of the forest services of the British

Commonwealth have found themselves in this predicament, which is by no means a new one. The rate of acquisition of land is still giving the Commission concern. The net additions of the past two years including acquired plantations have been substantially less than the areas planted. In 1951–52 they were less by eight thousand acres; this year by fourteen thousand acres. The total area of land acquired at September 30, 1953, was 1,909,400 acres. This comprised 1,181,400 acres classed as "Forest Land", which is either already planted or will be in due course, and 728,000 of "Other Land", which includes nurseries, rough grazing and agricultural land and other land unsuitable for planting. Twenty-six new forests were started during the year, nineteen in England, two in Scotland and five in Wales. The area planted was 67,610 acres, exceeding 1951–52 by almost six thousand acres. More than 118 million trees were used for the plantations and for replacing failures in recently planted ones. Fire damage was not high during the year.

The dedication scheme pursues its somewhat chequered course, dedication deeds being completed on 227 estates covering a total of 76,810 acres of woodland while another 139,730 acres of woodlands are in an advanced state of preparation; the total area thus approached a quarter of a million acres at the end of the year under review. It might be suggested as a matter for consideration, and to allay the difficulties of acquiring land, whether the Commission could not be advised to lay down a fixed minimum of land considered essential to be managed as State Forest and trust the private proprietor, with the Commission's advice and help where necessary, to work up to the balance of forest considered to be necessary for the requirements and protection of the population. France furnishes a good example. A considerable percentage of the French forests are privately owned and well managed. A question was once put to a senior French conservator of forests on the management of certain privately owned forests and whether the conservator ever gave advice, as they had a common boundary with the Government forests. He replied the private owner knew as much about forest management as he did. It may be concluded that British forest proprietors may in time attain as a body the same equality of knowledge as their French opposite numbers.

E. P. STEBBING

MANUFACTURE OF THE TEN-TOLA PRIMARY STANDARD WEIGHT FOR PAKISTAN

By DR. G. F. HODSMAN

Research Laboratory, L. Oertling, Ltd., St. Mary Cray, Kent

THE first primary standard of mass to be produced commercially in Britain for many years, the ten-tola primary standard for the Karachi Mint, Pakistan, has recently been completed by L. Oertling, Ltd., in conjunction with Johnson, Matthey and Co., Ltd. (see *Nature*, August 14, p. 206). The standard of mass has been prepared to an exacting specification for the Pakistan Government, and its manufacture involved a number of special problems which are of general interest, especially to those concerned with precision weighing.

In order that a self-consistent system of weights can be established throughout the world, weights must be related through individual manufacturers' standards to some recognized ultimate standard of mass. It is not yet possible to rely on any natural phenomenon for such a standard, as is possible, for example, with length, which can be related to wavelengths of light. Recourse must of necessity be made to the mass of an actual piece of material, which in the case of metric weights is the International Kilogramme, located at the Bureau International des Poids et Mesures at Sèvres, near Paris. Most countries, including Britain, have primary standards of mass, which form the basis of their own weight system, the primary standard in Britain being the Imperial Pound. The weight system in Pakistan is based on the tola, which is defined as 180 grains (7,000 grains equals one imperial pound); the recently completed primary standard of 10 tolas thus has a mass of 1,800 grains (about 120 gm.).

A satisfactory primary standard must fulfil a number of requirements, the most important of which is stability, and its construction must be such as to ensure constancy and reliability of mass over a period of many years. The Imperial Pound, for example, is believed to have remained constant within one part in five million during the past seventy years. It is the achieving of this stability which presents the manufacturer with some of his most difficult problems.

The primary standard should be as near its nominal mass as is reasonably possible in order to avoid the difficulties surrounding the use of small 'make-weights' when comparing the standard with sub-standards. The standard should also be of reasonable size in relation to the sub-multiples and multiples in common use. For this reason, the 10 tola has been chosen as the primary standard as being a better intermediate value than 1 tola, which would involve difficulties in standardizing large multiples.

The Pakistan standard is made from an alloy containing 90 per cent platinum and 10 per cent iridium—an alloy which experience has shown to be exceptionally stable and durable. Since both these metals have a high density, the weight occupies a small volume and consequently has a small surface area, which also enhances stability. The density of the weight must not be less than 21·50 gm./ml. at 20° C. to ensure that it is sufficiently free from cavities and inclusions, which might affect its stability.

The alloy billet was forged by the firm of Johnson, Matthey and Co., Ltd., in Hatton Garden, London, and was subjected to gamma-ray examination to reveal any major internal defect. It was then roughly turned and polished and subjected to a density determination by the National Physical Laboratory at Teddington. The billet used for the weight was free from all inclusions and achieved a density of 21·54 gm./ml., which indicates a high degree of freedom from inclusions.

The shape of the final weight is a simple cylinder with a height and diameter of approximately one inch, the under-surface being relieved over its central portion, to provide an annular seating for the weight and to minimize the risk of foreign matter adhering to the under-surface when the weight is in use.

The mass of the weight was required to be adjusted within ± 0·005 grain (that is, ± 0·3 mgm.), which is about three parts per million of nominal value; the actual mass of the weight was required to be known within ± 0·0002 grain. In addition, a high degree of surface finish is necessary, for any imperfections in the surface are centres of potential corrosion and dust location. The problem facing the manufacturer, therefore, is gradually to improve the surface finish, removing smaller and smaller amounts of material as the nominal value is approached so that correct mass and optimum polish are achieved simultaneously. If the correct mass is achieved before optimum polish, the surface defects cannot be removed and the weight becomes scrap metal. If optimum polish is achieved before correct mass, it is difficult and sometimes impossible to reduce to correct mass without damaging the surface. The simultaneous achievement of these twin conditions is a process requiring exceptional skill by the polisher, together with a series of accurate weighings. It is a process which occupies many months of painstaking and patient work using successively finer and finer polishes. The manipulation of the weight during the long period of adjustment, with the ever-present necessity of avoiding damage throughout every second of this time, imposes a considerable strain on the adjuster.

Primary standards are standards of mass and, therefore, when compared in air with standards of different density, allowance must be made for the different buoyancy effects on the two sides of the balance. For the adjustment of the Pakistan standard, a secondary standard made from an alloy of 80 per cent nickel and 20 per cent chromium was used as a counterpoise. This counterpoise was prepared, finished and adjusted in the same way as the standard and was calibrated for mass and density by the National Physical Laboratory. The Pakistan standard was then compared with this nickel–chromium standard on a reference balance built by L. Oertling specially for the work. The balance was capable of indicating weight differences of 0·01 mgm. with a load of 120 gm. in each pan. At the final adjustment stages, Gaussian weighings were used, the platinum standard being allowed forty-eight hours to become stabilized after each adjustment and before re-weighing.

The final certification of the weight by the National Physical Laboratory records a value of 1800·0007 grains for the mass, the deviation from nominal value being only 0·0007 grain. This deviation is about one part in three million and is comfortably within the permitted tolerance.

THE *O* CHROMOSOMES AND THE DISTRIBUTION OF THE DENTAL FRICATIVES IN EUROPE

By R. W. THOMPSON

University College of the West Indies, Jamaica

IN their well-known introduction[1] to genetics, Darlington and Mather bring up once more the question of the relationship between race and language. Their thesis is that the 64·5 per cent line for the *O* chromosomes (in the *A*—*B*—*O* series) coincides with the boundary which separates those Europeans who pronounce a *TH* sound (as in English *think* and *then*; *AIP* notation [θ] and [ð]) from those who do not. Their story is ingenious, as are their sketch-maps. Unfortunately, they have simplified the issue and arrived at conclusions which we are not yet in a position to accept in the light of present knowledge. They themselves would appear to regard their paragraphs on this subject as mainly speculative.

Let us agree with Darlington and Mather's definition of *TH* as a 'dental fricative', unvoiced [θ] as in English *think* and voiced [ð] as in English *then*. Sounds with approximately the same values as these exist in other European languages but are often developments from a completely different phonetic base. For example, the [θ] of Spanish in *cielo* is derived from a primitive *k*-sound, whereas that of English *thin* descends from a postulated primitive *t*. While [θ], [ð] do not occur in many of the European languages, there is no reason for believing that normal Europeans have any *congenital* difficulty in pronouncing them. Children rapidly learn to discard myriads of sounds which do not conform to the type found in the language used by their parents.

At this point we shall look at the map of Europe and see what the position is in several of the areas where Darlington and Mather have registered the presence of the dental fricatives.

In the west, in Ireland it is claimed that the dental fricatives are extant. For some reason, West Kerry is marked 'extant variable'. The facts are that this group of sounds is absent from popular speech over most of Ireland, and only parts of the north-east could be labelled 'extant variable'. Orthography often confuses the layman. It should therefore be remembered that forms such as stage-Irish 'butther', 'Pathrick', 'murdher' represent a special group of sounds for which there is no provision in standard English spelling. They are 'velarized dental plosives' (voiced or unvoiced) and are produced by pressing the tip and blade of the tongue against the upper incisors. In the formation of these sounds the breath is cut off as in the production of English [*t*] and [*d*]. In the pronunciation of [θ], [ð] the flow of breath is continuous. The velarized dental plosives in the English of Ireland are examples of Gaelic 'substratum'. Children of Irish parentage, born in London, seem to have no difficulty in pronouncing [θ], [ð] in the English manner. One feels that the children of those who 'could not frame to pronounce' the word 'shibboleth' (Judges, xii, 4–6), if taken early enough, could have been taught to palatalize initial *s* in spite of the arrangement of their chromosomes.

Turning again to Spain, where orthographic *c* (before *e* and *i*) and *z* = [θ] in the standard language, we see that the phenomenon has not yet covered the whole country. Throughout Catalonia and Valencia in the east, the mother-tongue of the people shows *c*, *z* = [*s*], [*z*], respectively. Yet when Catalans or Valencians are obliged to speak the national language in the school or upon official occasions they are quite capable of pronouncing the *c* and the *z* in the Castilian fashion. In the south of Spain both these letters are pronounced somewhat like an English [*s*] in many districts, although written *s* is sometimes rendered as [θ]. Which means that *si señor* may sound like *thee thenyor*. Now so far as the relationship between the use of [θ] and blood group genes is concerned, in Spain we must realize that (according to the recent researches of the late Amado Alonso[2]) the final passage of earlier *ts* and *dz* (written *c*, *ç*, *z*) > θ was not complete in either the dialect of Castile or in the national language until the late sixteenth century. By about this same time these sounds had passed to [s] in America, southern Spain, and in the Judæo-Spanish of the descendants of the Jews expelled by Ferdinand and Isabella in 1492 and living in North Africa, the Balkans and elsewhere. Are we not justified in regarding the apparent coincidence of linguistic and genetic phenomena as irrelevant?

Portugal apparently lies beyond the 64·5 line and according to Darlington and Mather the only traces of *TH* are to be found in two areas. In one they claim that it disappeared before 1000 B.C. and in the other it is said to be 'extant variable'. Yet the facts speak differently. In peninsular Portuguese intervocalic *d* is often pronounced [ð] as in the other Hispanic languages and dialects.

In the Greek of Demosthenes[3] the group χ, θ, φ was pronounced [*kh*], [*th*], [*ph*]. In modern Greek (and, indeed, from early in the present era) they have the following values: χ = something like the two chief *ch* sounds of modern German; θ = [θ]; φ = [*f*]. One asks if before the passage of *t* + *h* > [θ] the *AB*/*O* blood group genes fought a bloody underground battle in the bodies of the Ancient Greeks.

The fundamental question is whether or not any race is incapable of or averse to pronouncing any given sound. From my own experience in various countries, such a theory cannot be proved. Here in Jamaica, when I listen in on the radio I cannot tell if the speaker is black, white or of mixed race. In Jamaica the educated black or brown man will say 'think', 'the', 'then' as easily as an Englishman. The poor-white farmer says 'dis', 'dat', 'dese', 'dose', 'ting', 'tink' just like his dark neighbours. The black man says 'tink' because his father did and not because of a certain arrangement of genes. The first of his ancestors to speak a kind of English, lacking [θ], [ð] in his own West African dialect, substituted a *t*- or a *d*-sound, the nearest equivalents he could find. In the same way, a Frenchman or a German may produce 'seenk' for 'think' and 'zees', 'zat', 'zeese', 'zose' for 'this', 'that', 'these', 'those', but not because he has anything wrong with his chromosomes. Indeed, if he were to allow his children to be brought up in Britain he would find that it was no more difficult for them to pronounce in the English way than for an English child, reared in France or Scotland, to say "*de bon vin blanc*" or "*It's a braw, bricht, munelicht nicht, the nicht*".

We admit that the speech organs of various races vary in shape, as does the texture of the hair, the colour of the skin or the form of the lips or nose. The only influences these variations could have on the production of speech is on 'timbre', and even this, as may be inferred from my remarks above, is not significant over the radio.

Finally, it does not seem that any valid conclusions can be drawn from the apparent coincidence of isogenic lines for blood-group frequencies and isophones for the distribution of *TH* = [θ], [ð] in Europe, in the light of our present knowledge of race and historical phonetics in that continent. Most linguists will continue to feel that human environment is a more powerful influence on language than heredity.

MEASUREMENT OF RHODOPSIN IN THE LIVING HUMAN EYE

By Dr. W. A. H. RUSHTON, F.R.S., and Dr. F. W. CAMPBELL

Department of Physiology, University of Cambridge

THE photopigment rhodopsin has long been known to be the chemical basis of scotopic (twilight) vision, and its bleaching and resynthesis have generally been held to underlie the phenomenon of light- and dark-adaptation. It has never been possible, however, actually to measure the rhodopsin-level in the living human eye, except for the incidental observations of Brindley and Willmer[1], who, however, were unable to avoid rapid bleaching of the pigment by the light used to measure it.

In order to work at substantially lower luminance-levels, a photocell technique has been developed. Successful applications[2-4] of the method to the cat and albino rabbit (where the back-reflexion of light from the eye is strong) encouraged us to proceed to the far more difficult case of the human eye, and we now appear to be able to measure changes in the rhodopsin-level with an accuracy of about 5 per cent of the full dark-adapted amount, each measurement taking 5–10 sec. to make.

Light from a bright source passes through a rotating colour-wheel so that the light transmitted is alternately orange and blue-green (Fig. 1). This passes through a hole in the silvering of a cover-slip and is focused upon the cornea in a 2° pencil. Light reflected from behind the small illuminated patch of retina passes back through the dilated pupil and, after reflexion in the mirror, is focused upon the cathode of a photomultiplier cell (type 931 *A*), the output of which gives the signals alternately for orange and blue-green light. These two signals are separated by passing through a commutator mounted upon the shaft of the colour wheel. Condensers connected to the grids of two cathode followers act as reservoirs for the levels of the two signals, and a galvanometer across the cathodes gives a null indication when the levels are equal.

Nearly all the light entering the photocell has passed twice through the rhodopsin of the retina. This will scarcely affect the orange signal since rhodopsin is nearly transparent to orange light, but it absorbs maximally in the blue-green, so a change in the rhodopsin density will upset the null balance of the galvanometer. This may be restored by a corresponding change in the position of a purple wedge in the path of the incident light. The amount of purple wedge added is proportional to the amount of visual purple lost, which may thus be read directly. The technique is seen to have the usual advantages of a null method; it is relatively unaffected by changes of light source, of signal amplification and of small eye movements, though all these have been kept as steady as practicable.

If a fairly bright light is shone into the eye, rhodopsin is bleached, at first quickly and later more slowly as less and less pigment remains to absorb the light. Fig. 2 shows this curve measured in terms of the setting of the wedge. There are four different experiments: ○ and × show the bleaching of a 2° area of the retina 20° temporal to the fovea (the two experiments were similar but were performed three days apart to show the degree of repeatability);

Fig. 1. Rotary rhodopsinometer

experiments ● and — were similar, but the areas measured were the fovea and the blind spot, respectively. The actual level of the plotted results is arbitrary; what is significant is that there is no bleaching in the fovea and blind spot. They are the only areas in the retina devoid of rhodopsin and they are the only places where we have found no bleaching. This leads us to believe that it is the bleaching of rhodopsin that we are measuring; the spectral sensitivity also corresponds to what would be expected from the bleaching of rhodopsin[4].

The sensitivity has been measured by finding the bleaching-rates in lights of different colours. As is well known, the scotopic visibility of any colour corresponds very closely to its power of bleaching rhodopsin. So the subject (W. A. H. R.) first matched the various coloured lights under scotopic conditions, and then his retina was bleached by exact multiples of these matched intensities (some 10^5 times as strong). Each colour gave the same rate of bleaching within 20 per cent as measured by the displacement of the purple wedge, though of course the orange light appeared enormously brighter than the blue due to the activation of the cones.

Rhodopsin-Level and Visual Function

It has been widely held that a principal cause of light adaptation is the bleaching away of rhodopsin so that only a small fraction of the pigment remains to absorb the necessary quanta. Among many who have opposed this, Granit *et al.*[7] have not found the expected correlation in animals' eyes. Baumgardt[8] has calculated that insufficient quanta are absorbed to produce significant bleaching at the low luminances where the bleaching hypothesis was often used, and Rushton and Cohen[9] showed experimentally that some fifty-fold change of threshold was produced by less than 2 per cent bleaching of rhodopsin. This latter experiment has recently been repeated and confirmed by Wald and Hubbard[10].

All this work gives an upper limit to the amount of bleaching possible by assuming that no regeneration occurs, for there has been no reliable way of estimating the rate of regeneration. The present technique allows us to measure the rhodopsin-level directly and rapidly in various conditions of illumination. Work upon the kinetics has only just begun; but the following results are at once apparent. (*a*) The rhodopsin-level is in fact not appreciably altered by brief light adaptations such as those used by Rushton and Cohen[9]. (*b*) After strong bleaching, the subsequent return of the rhodopsin-level to its full concentration follows an exponential curve with half-return constant of about 7 min. (*c*) At moderate room illuminations there is not more than 10 per cent of the rhodopsin bleached when equilibrium is reached.

This seems to establish that unless fairly bright photopic illumination is used, there is no appreciable change in the density of retinal rhodopsin. Thus changes in visual sensitivity cannot be due to an alteration in the chance of a quantum being absorbed; it must be entirely due to a change in the efficacy of the quantum when it is absorbed.

We are indebted to the W. H. Ross Foundation and the Medical Research Council for defraying the cost of the apparatus.

Infra-Red Spectra of Coals

In the past, the infra-red spectra of solid materials which cannot readily be dissolved or prepared in very thin sheets have been determined by the use of suspensions of the substances in liquid paraffin ('Nujol'). We have reported spectra of some coals obtained in this manner[1], and observed that prolonged grinding is necessary in order to reduce the loss of radiation by scattering.

We have recently experimented with the new technique described by Schiedt[2] and Stimson[3], in which the substance to be examined is compressed with potassium bromide to give a translucent disk, and we have found that careful preliminary grinding of the coal and effective mixing of the coal and potassium bromide are of considerable importance. The influence of grinding time has been determined by preparing disks after milling 0·3 gm. coal for measured intervals of time in a high-speed miniature ball-mill. Fig. 1 shows the spectra of an anthracite milled for 5, 13 and 20 hr. It will be noted that after 5 hr. milling, the general level of absorption is high; after 13 hr., radiation scattering by the coal particles is high from 3,500 to about 1,500 cm.$^{-1}$ but the general level of absorption is lower. After 20 hr., the general level of absorption shows little further change, and radiation scattering, even at the high-frequency end of the spectrum, appears insignificant. Bergmann has recently reported[4] coal spectra obtained by this method; but there is evidence that scattering is still appreciable in the region 3,500–2,400 cm.$^{-1}$ although the general level of absorption is low. This is probably due to insufficient grinding of the coal sample.

In examining a series of coals, we have consequently adopted the policy of milling each for such time that further milling produced no change in the spectrum; in the case of the anthracite, the time involved was 20 hr., whereas for a bituminous coal 5 hr. was sufficient. Fig. 2 shows the spectra so obtained from five coals, each predominantly vitrain, of ash content less than 1·5 per cent, covering the range from class 100 (anthracite) to class 900 (bituminous). The spectra were recorded on a Grubb–Parsons infra-red spectrometer using a sodium chloride prism. A detailed interpretation of these spectra will be reported elsewhere in due course, but a few general observations follow.

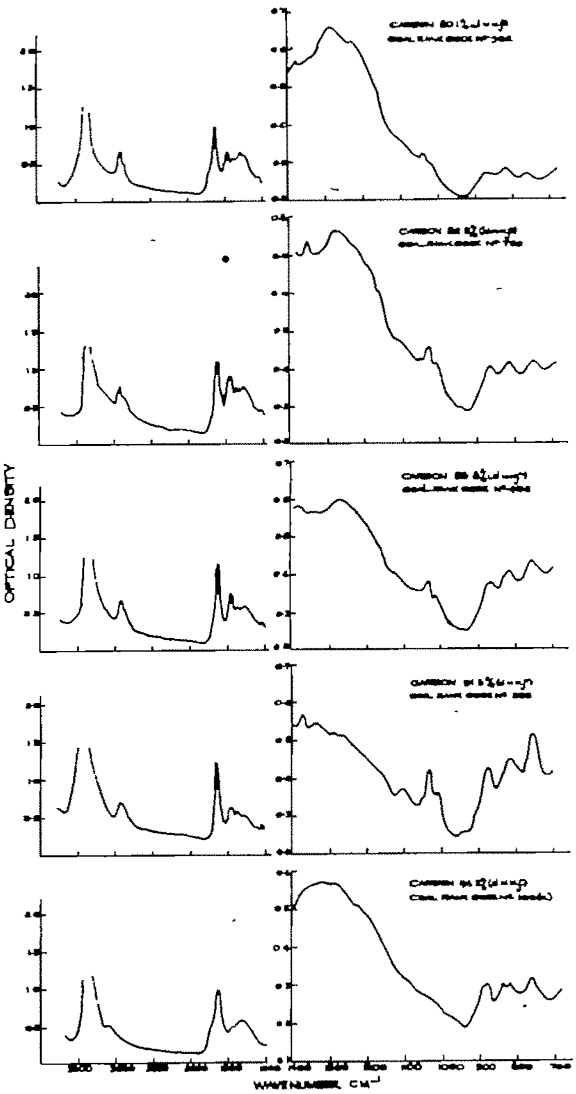

Fig. 2. Infra-red spectra of coals of different rank

The sample disks of all the coals contain the same amounts of coal and potassium bromide (weight of disk 350 mgm., thickness of disk 1·5 mm., coal percentage 0·5) and the spectra may be compared one with another on a reasonably accurate quantitative basis. This represents a considerable improvement on the 'Nujol' technique, where comparison between spectra was only qualitative.

It may therefore be stated that there is little variation in the general level of absorption throughout the range of coals in Fig. 2. The contrary assertion, that the general level of absorption

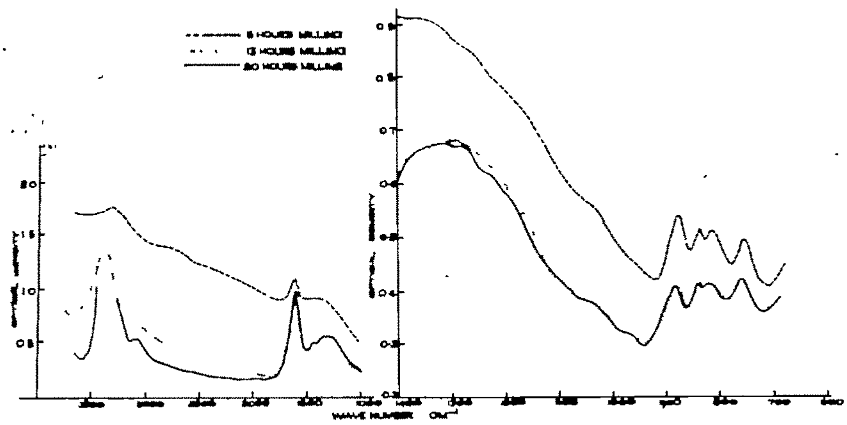

Fig. 1. Infra-red spectra of anthracite and effect of milling-time

rises with the carbon content, has previously been made[5,6], on the evidence of spectra derived from 'Nujol' mulls. It now appears that what was interpreted as a high general level of true absorption in the anthracites was actually a high degree of scattering, caused either by inadequate grinding or by subsequent aggregation of particles in the suspension.

The regions of the spectra about 2,850, 1,450 and 1,370 cm.$^{-1}$, which are obscured by the paraffinic CH absorptions from 'Nujol', are now observable. On the other hand, we have found it necessary to record the spectrum fairly soon after a disk is made, because disks which have been stored for some time show additional absorption peaks at 1,110, 1,043, 997 and 918 cm.$^{-1}$, the intensities increasing with time. The cause of this phenomenon is being sought.

Heats of Reaction during Carbonization as deduced from Temperature Surveys of a Coke Oven

Metallurgical coke is made by carbonizing coal in an oven that consists essentially of two heated walls spaced some 40–45 cm. apart. Coal is charged into the already heated oven, and the isotherms in the coal are found to be substantially pairs of planes parallel to the oven walls. With the passage of time, both components of any pair of isothermal planes will advance through the charge to the centre of the oven. As the dimensions of the walls are large with respect to their spacing, the system may be regarded for the purpose of analysis as one-dimensional and, if the thermal properties of the charge are known, the temperature distribution at any time should be determinable by solution of the one-dimensional case of the heat-flow equation.

This was attempted for the case of a 10-cwt. experimental coke oven charged with three different coals. Temperature histories were recorded for different points across the oven, and the thermal properties of the coals used were measured in the laboratory. Thermal conductivities showed large changes with temperature (Fig. 1), but the product of density and specific heat showed only relatively small (10 per cent) changes during carbonization.

Numerical solution of the heat-flow equation using the experimental data would have been exceedingly tedious, so an analogue method of solution due to Liebmann[1] was used. In this method time is treated in iterative steps, the solution over each time-interval being obtained from an electrical resistance analogue in which the electrical parameters (conductance, voltage, etc.) are adjusted to correspond to the values appropriate to the thermal parameters (conductance, temperature, etc.) for that step.

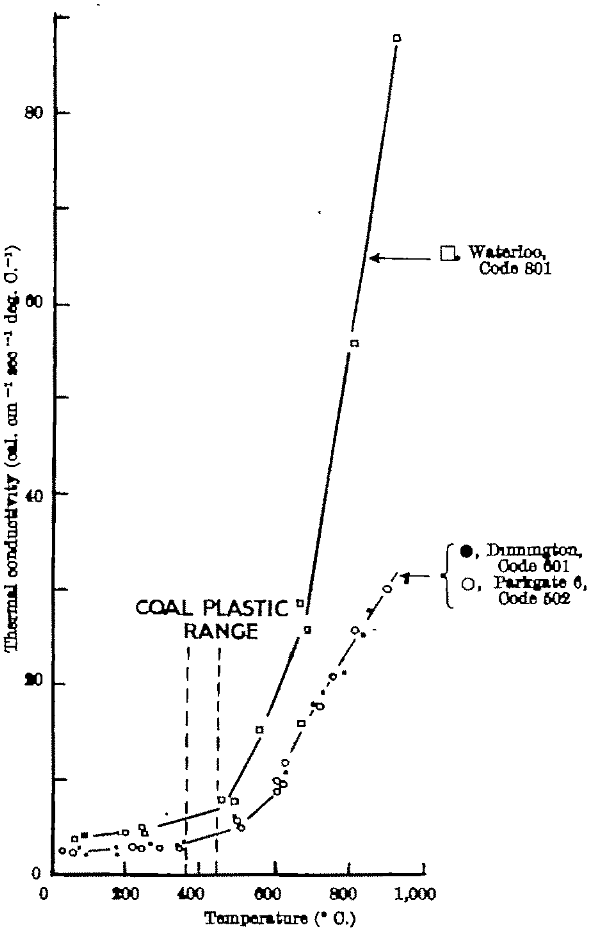

Fig. 1. Thermal conductivity as a function of temperature for the three coals used

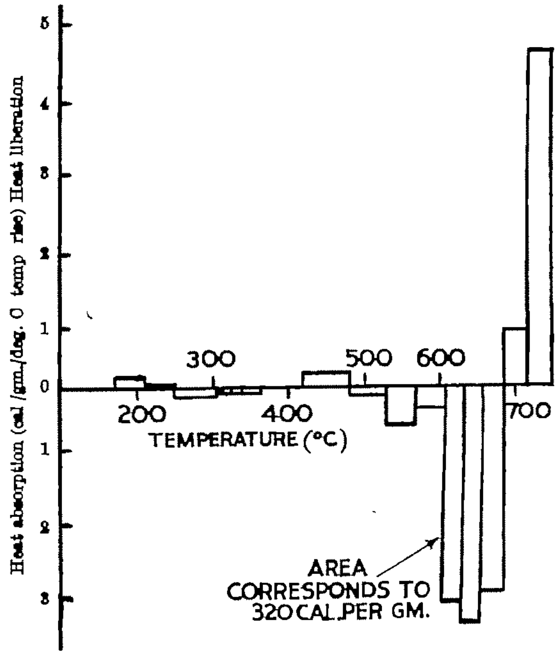

Rate of heating: about 3 deg. C./min. Coal: Parkgate 6, N.C.B. Code 502

Fig. 2. Heat of reaction in cal. per gm. per deg. C temperature rise as a function of temperature for a coking coal (Parkgate 6)

It is found in all cases that the calculated temperatures are first higher, but later lower, than those observed experimentally, the change-over occurring at about 740° C. These discrepancies are larger than can be explained by gas convection or radiation effects in the coke oven, and are believed to be due to the carbonization process being on the average endothermic below a temperature near 700° C. and exothermic above this temperature. To estimate the magnitude of the heat absorption/liberation, the analogue computing technique due to Liebmann is sufficiently flexible to be used in reverse. The computer was made to follow the observed temperature histories and note was taken of the heat absorption/liberation that had to be postulated in order to make it do this. A typical result of such a calculation for a rate of heating of 3 deg. C. per minute is shown in Fig. 2. It was found that heat is absorbed in the range 150°–700° C. Of the three coals tested, Parkgate 6 absorbs 320 cal. per gm., Dinnington absorbs 170 cal. per gm. and Waterloo absorbs 780 cal. per gm. Above 700° C. all three coals are exothermic, releasing some hundreds of calories per gm. between 700° and 800° C. The calculation could not be carried beyond 800° C. owing to difficulties in experimental technique, but two of the coals (Parkgate 6, Dinnington) are known to be still exothermic above 900° C. This was seen from the experimental temperature surveys, which show that at about 900° C. the temperature throughout the oven becomes uniform, and at this point the temperature at the centre is still rising above that of the outside at a rate of about 0·3 deg. C. per min., eventually becoming some 50 deg. hotter than the walls.

'Reaction Time' of Cast Trinitrotoluene as a Function of the Rate of Charge Cooling

FOR charge diameters greater than 1 in., the detonation velocity of 'confined' T.N.T., that is, T.N.T. cast in metal tubes, increases only very slightly with increasing charge diameter, indicating a very short reaction-time ($\sim 10^{-8}$ sec.) for the primary decomposition process of this explosive. The experimental results already reported[1] suggested that this small change might be associated with the existence of the 'surface chilled' layer which would be present in all heavily confined charges and would vary little in character with changes in charge diameter. It was decided, therefore, to re-investigate the velocity – charge diameter relationship for T.N.T. under conditions of charge cooling such that very different degrees of surface chilling were operative during the initial solidification phase.

The T.N.T. was cast in heavy seamless copper tubing with internal diameters of 1½ in., 2 in. and 3 in. using the following two casting techniques:

(1) *Ordinary 'clear cast' T.N.T.* Molten T.N.T. at 105° C. was poured into the cold casing and allowed to cool without interruption at room temperature. Casting-heads were employed, so that stirring during solidification could be dispensed with but cavitation effects avoided.

(2) *Ordinary 'clear cast' T.N.T. in heated cases—slow cooled.* The casings were first heated to 80–85° C. in a large steam-heated vessel. The T.N.T. at 105° C. was then poured in so as to fill completely the charge casing and casting-head, the steam turned off, the vessel covered and the charge then allowed to cool. Because of the large heat capacity of the containing vessel, cooling was very slow, complete solidification requiring 4–6 hr.

The degree of confinement (S) was maintained constant at the various diameters ($S = 3{\cdot}10$–$3{\cdot}28$ gm./sq. cm.). Two velocities were measured on each charge over 30 cm. intervals using the Dautriche[2] method, commencing at distances of 10 cm. and 20 cm. from the initiated end. This staggering of the timing intervals afforded a rough check on the stability of the detonation velocity along the charge. The results obtained are summarized in Table 1.

Table 1

Charge diameter (in.)	Density, Δ (gm./c.c.)	Type of cooling	Average velocity of detonation (m./sec.)
1	1·58	Ordinary	6,760
1	1·57	Slow	5,900
1½	1·59	Ordinary	6,710
1½	1·58	Slow	6,280
2	1·59	Ordinary	6,845
2	1·57	Slow	6,480
3	1·56	Slow	6,480

A much greater scatter among individual results was evident with the slowly cooled charges, as might be expected since uniformity of crystal size and orientation are more difficult to ensure from one charge to the next.

If U is the observed detonation velocity and R the charge radius, plots of $1/U^2$ against $1/R$ are approximately linear for both cooling rates, and on the basis of the theoretical treatment of Jones and Stickland[3] the slopes of these lines lead to estimates of the effective reaction-time for the two types of charges, that is, to the time occupied by the primary decomposition process that determines the extent to which lateral energy losses may occur, and hence the detonation velocity. The slowly cooled charges show a ten-fold increase in reaction time. The two lines obtained in the present experiments are but two representatives of an infinite number of possibilities between certain limits. Theoretically, these two limits are on one hand liquid T.N.T. in which the 'crystallites' are of molecular dimensions, and on the other hand a charge consisting of a single large crystal, in which case the reaction-time would probably be so long that the term detonation would no longer be applicable.

It is well known that the grain size of T.N.T. increases with decreased rates of cooling, and while the possibility of changes in crystal orientation must be borne in mind, in the absence of any direct evidence to show that such changes may significantly affect the velocity of detonation, it seems logical to relate the changes in reaction-time to changes in grain-size, the reaction-time decreasing as the internal surface is increased.

It appears that in cast-confined charges there is at the surface a fine-grained outer layer with a higher intrinsic detonation velocity (that is, shorter reaction time) than the core. The situation is somewhat akin to a composite charge composed of cylinders of different detonation velocities. The detonation velocity is then always that of the component with the highest detonation velocity, and whether the high-velocity component is on the outside or the inside it will still be the rate-determining factor for the charge as a whole. In the case of confined charges, the finely crystalline surface-chilled layer is probably very thin, and the effect produced, therefore, may be of an intermediate character[3]; but it will be out of all proportion to its size because it is the high-velocity component.

The dependence of reaction-time on grain-size in the case of cast explosives has an important bearing on the various theories put forward to account for the initiation of the decomposition at the detonation front. It is in accord with the hypothesis of heterogeneous explosive decomposition involving a reaction between a gaseous and a solid phase, the major part of the reaction involving the erosion of the crystallites by the hot gases arising from the already decomposed explosive.

We acknowledge our thanks to the Chief Scientist, Ministry of Supply, for permission to publish these results. This work was carried out during the latter years of the Second World War.

Oxidation Changes in Natural Ilmenite

NAGATA has discussed the occurrence of three magnetic components of the Haruna and Asio rocks exhibiting thermo-remanent reversals[1]. The properties of the *B*-component appear to be very similar to those of a material recently examined in this laboratory. We have been investigating the impure ilmenite concentrate obtained as a by-product in the winning of rutile from beach sands on the east coast of Australia.

This concentrate may be refined magnetically to produce a highly magnetic fraction (containing magnetite and other highly magnetic materials and comprising about 2 per cent by weight of the total concentrate) together with fractions of weakly ferromagnetic material closely related to ilmenite which have volume magnetic susceptibility in the range $0·4 \times 10^{-3}$ to $1·1 \times 10^{-3}$ c.g.s.u. at low magnetizing fields. This variation in susceptibility is associated with a variation in apparent ferric to ferrous iron ratio, the range being 0·40–0·65, while the titanium (TiO_2) content is within the range (50 ± 2) weight per cent. Manganese is present to about 2 per cent by weight.

When any magnetic fraction of this 'ilmenite' is heated in air at a temperature in excess of 600° and below 800° C., an oxidation process occurs during which the apparent ferric to ferrous iron ratio rises to approximately 1·3 and, on cooling, the material shows much enhanced magnetic properties. The value of the initial susceptibility for a sample of firmly packed grains is approximately 2×10^{-3} c.g.s.u., about one-fifth of that for a similar sample of natural magnetite.

Observations have been made of the crystal structure and magnetic properties of this 'magnetic ilmenite' derived from different magnetic fractions of the original ilmenite, and no significant variation has been noted. Debye–Scherrer X-ray photographs were made for a particular fraction of the ilmenite and for the 'magnetic ilmenite' derived from this fraction, and these were compared. The pattern due to 'magnetic ilmenite' may be described as the superposition of a set of lines which were indistinguishable from the lines of the original fraction and of lines due to rutile. No difference has yet been noted by mineragraphic examination of the two sets of grains.

The Curie point of the 'magnetic ilmenite' is between 100° and 200° C., and the dependence on temperature of the magnetic properties is otherwise consistent with that for Nagata's *B*-component[1b].

Qualitative tests show that crystals of Norwegian ilmenite may similarly be changed to 'magnetic ilmenite', but the necessary temperature and time of heating will depend on the size of the crystals.

Prolonged roasting of the natural ilmenite at temperatures in excess of 800° C. results in the conversion of the iron to the ferric form. The final product is weakly ferromagnetic, and at low magnetizing fields the volume magnetic susceptibility is about $0·3 \times 10^{-3}$ c.g.s.u. The Debye–Scherrer X-ray pattern may be resolved into a set of rutile lines and a set of lines due to a tetragonal crystal with lattice parameters $a = 4·861$ A., $c = 6·625$ A., $c/a = 1·363$.

This investigation has been carried out in the J. I. Carroll Research Laboratory of this School and we wish to acknowledge the guidance of Prof. C. J. Milner.

Flow Potentials in Hyaluronate Solutions

RECENTLY, it was found in this Institute[1] that solutions of potassium hyaluronate give elastic recoil when examined in a glass capillary by the 'œstroscope' technique[2]. This was ascribed to the long, flexible hyaluronate ions, which presumably form a lace-work all through the solution, knitted together by hydrogen-bond cross-links and adhering to the glass wall. The potassium ions are obviously more free to move, but in flowing, as soon as they tend to run in advance of the negatively charged hyaluronate polyions, a potential must arise to preserve electroneutrality.

In connexion with another recent finding in this Institute, that the endolymph of the inner ear in sharks contains a fair amount of hyaluronic acid[3], the possible occurrence of such flow potentials in hyaluronate solutions opened up an interesting possibility to account for the microphonic potentials detected in the inner ear by Wever and Bray[4] and thereby also to contribute to our understanding of the mechanism of perception in the inner ear.

To test the actual occurrence of such potentials we made a primitive model. From a screened capillary

U-tube in which a column of 0·5 per cent hyaluronic acid solution could be moved by gentle suction and blowing, the potentials between silver – silver chloride electrodes dipping through the two surfaces were led to the symmetrical d.c. input of a cathode ray oscillograph (*OSG* 41, Radiometer, Copenhagen; input impedance 1 MΩ).

In this way potentials of 6–10 mV. were obtained, positive at the advancing surface and persisting until the liquid is allowed to return towards its original position. In special cases much higher potentials (20–25 mV.) were found: namely, at the first displacement after filling with fresh solution, and when after blowing out the bulk of the solution we filled the tube with water, which slowly dissolved the adsorbed film. With pure water, and also with a 10 per cent gum arabic solution, potential shifts during the same manipulations were equal to or less than the noise-level of 1–2 mV.

A more detailed study of the potentials is planned, and we also hope in a later publication to give a detailed discussion of the significance of these potentials in connexion with the function of the inner ear.

We are indebted to the head of this Institute, Prof. J. A. Christiansen, for his interest in this work.

Protective Effect of *d,l*-α-Octadecylglycerol-ether in Mice given Total Body X-Irradiation

Sandler[1] claimed that the protective factor against benzene poisoning found in yellow bone marrow is batyl alcohol or one of its esters. Since batyl alcohol is found in those organs which are said to contain a humoral factor that protects animals against the acute phase of irradiation injury[2], the following experiments were carried out. Sixty adult white male mice of an inbred strain (16 years) were irradiated with a therapeutic X-ray machine, 165 kV., 15 m.amp., filters 0·5 mm. copper + 1 mm. aluminium, target distance 60 cm., irradiation time 25 min., total dose 750 r. (air). Two hours after the end of the irradiation, thirty animals chosen at random were given 0·1 ml. of peanut oil subcutaneously, the others the same volume of peanut oil containing 2·5 mgm. *dl*-batyl alcohol per ml. These injections were repeated every second day until 1·75 mgm. of *dl*-batyl alcohol or a corresponding amount of the solvent had been administered to the animals. The 30-day lethality for the animals treated with batyl alcohol was seventeen out of thirty and for the controls twenty-six out of thirty. The difference is statistically significant ($P < 0·01$).

I have tried to find the optimal dosages for the synthetic alcohol and then for the naturally occurring alkoxyglycerol esters. From these experiments it can be concluded that in certain circumstances both these agents have a beneficial therapeutic effect on irradiation injury in mice; overdosage, however, increases the lethality. Further studies are in progress.

Simultaneously, but independently, Brohult *et al.* [following communication] have studied the effect of alkoxyglycerols in the treatment of leukopænia caused by irradiation.

Alkoxyglycerols in the Treatment of Leukopænia caused by Irradiation

During irradiation therapy the blood-forming tissues are subjected to a great strain. At first this becomes noticeable in the form of a decreased white-cell count. This leucopænia sometimes necessitates an interruption of the irradiation therapy and consequently the time of treatment of the patient is prolonged.

Since the autumn of 1953, we have administered *per os* α-alkoxyglycerol preparations to some patients treated with irradiation. The alkoxyglycerols and particularly their esters are present in the lipids of several animal organs. One of the alkoxyglycerols, namely, batyl alcohol, is found in, for example, bone marrow fat[1], it forms part of the 'non-saponifiable' spleen lipids[2], and in the red cells[3]. It is also found in the liver lipids, and particularly in the liver lipids of sharks. Its presence in the red cells and in blood-forming organs is noteworthy.

The idea of administering extracts of erythropoietic tissues in disorders in the erythropoietic process is not new. Thus Marberg and Wiles[4] reported that the non-saponifiable portion of yellow bone marrow fat from cattle was effective in the treatment of agranulocytosis and leukopænia. Later Sandler[5] studied the erythropoietic effect of yellow bone-marrow extracts as well as batyl alcohol. Sandler states that a definite response in the reticulocyte count was obtained when batyl alcohol was administered orally to normal subjects.

We examined the effect in 1952 of giving the non-saponifiable portion of bone fats *per os* to some cases of leukæmia in children. We then continued with other preparations containing alkoxyglycerols and their esters in the form of concentrates. These concentrates had a higher potency than the bone-marrow preparations. The observations from some of these cases form the background of the experiments reported here.

To patients suffering from irradiation leukopænia, alkoxyglycerol esters were administered *per os* while the irradiation was continued. So far thirty-six cases have been studied. Of these, twenty-five responded to the therapy by an immediate increase in the white-cell count. In nine cases there was no further decrease in white cells after starting therapy. Only two cases showed a continued decrease in leucocytes.

A striking effect is illustrated by the following observations during the treatment of a nurse who had been occupied in radium therapy for some years. She had for more than a year a white-cell count of about 2,000 and was treated for five days with an alkoxyglycerol ester concentrate *per os* as the only therapy. Already after four days a white-cell count of 3,600 was reached. After withdrawal of medication, this level was maintained for five months with only one additional four-day treatment. A third period of four days of therapy followed after five months and resulted in a white-cell count of 4,200. Treatment for a few days obviously maintained the white-cell count on a normal level for a long period.

We thus conclude that treatment *per os* with alkoxyglycerols as well as their esters is a promising therapy against leukopenia caused by irradiation. The alkoxyglycerols might also give a more general protection of the blood-forming tissues against irradiation damages. A more detailed study of this subject, as well as of other effects of the alkoxyglycerols, will be published elsewhere.

Simultaneously, but independently, Edlund has studied the protective action of batyl alcohol on irradiated mice [see preceding communication].

Exchange of ^{14}C-Glucose-1-phosphate with Uridine-diphosphate-glucose by the Galacto-Waldenase System

A TWO-STEP reaction, as represented by reactions 1 and 2, has been proposed[1] for the enzymatic transformation of galactose-1-phosphate into glucose-1-phosphate :

$$\text{Gal-1-P} + \text{UDPG} \rightleftharpoons \text{G-1-P} + \text{UDPGal} \quad (1)$$

$$\text{UDPGal} \rightleftharpoons \text{UDPG} \quad (2)$$

Reaction 2 has been experimentally demonstrated[1]. Kalckar *et al.*[2] have recently reported as evidence for the occurrence of reaction 1 the formation of 1 mol. of glucose-1-phosphate per mol. of uridine-diphosphate-glucose and of galactose-1-phosphate consumed, when these two compounds are incubated with diluted *Saccharomyces fragilis* extract.

If the proposed mechanism is correct, incorporation of carbon-14 glucose into the uridine-diphosphate-glucose should occur when this compound and ^{14}C-glucose-1-phosphate are incubated with *S. fragilis* extract. The experiments reported here have shown this to be the case.

Since phosphoglucomutase is present in the crude *S. fragilis* extracts, ^{14}C-glucose-1-phosphate could be replaced by ^{14}C-glucose-6-phosphate. This was prepared by incubation of glucose labelled uniformly with carbon-14 plus adenosine triphosphate with partially purified yeast hexokinase. A preparation purified by the method of Berger *et al.*[3] up to step 4 was used. ^{14}C-glucose-6-phosphate was precipitated as barium salt, which was then dissolved and re-precipitated with barium and alcohol. A preparation devoid of reducing power and inorganic phosphate was obtained.

^{14}C-glucose-6-phosphate and uridine-diphosphate-glucose were incubated with dialysed *S. fragilis* extract under the conditions specified in Table 1. The reaction was stopped by adding to the incubated mixture four volumes of alcohol and 0·02 ml. of *M* acetic acid solution. The protein precipitate was centrifuged and washed twice with 70 per cent alcohol. Supernatants and washings were mixed and the resulting solutions evaporated *in vacuo* to dryness. The residues were taken up in distilled water, deposited on a sheet of Whatman No. 1 filter paper, and chromatographed with the acid ethanol–ammonium acetate solvent[4]. Areas on the paper carrying the equilibrium mixture of uridine-diphosphate-glucose (75 per cent) and uridine-diphosphate-galactose (25 per cent) were located by ultra-violet light and eluted with distilled water. The amount of this equilibrium mixture in the samples was determined by measuring the absorption of an aliquot at 260 mμ in a Beckman spectrophotometer. The carbon-14-labelled equilibrium mixture was determined by measuring the radioactivity of an aliquot evaporated on an aluminium disk, with a thin mica end-window Geiger–Müller tube and a 'Tracerlab' scaler. As is shown in Table 1, after 30 min. of incubation, the radioactivity of glucose-6-phosphate was equilibrated with that of the above equilibrium mixture. The small amount of radioactivity found in the latter incubated without uridine-diphosphate-glucose must be due to the presence of small amounts of this compound in the dialysed extract.

When in the experiment described in Table 1, ^{14}C-glucose-6-phosphate was replaced by ^{14}C-glucose, no radioactivity was incorporated into the uridine-diphosphate-glucose.

Kalckar *et al.*[5] demonstrated the occurrence in *S. fragilis* extracts of reaction 3, catalysed by a specific pyrophosphorylase, which has been named 'uridyl transferase'[2] :

$$\text{UDPG} + \text{PP} \rightleftharpoons \text{G-1-P} + \text{UTP}. \quad (3)$$

The incorporation of ^{14}C-glucose into uridine-diphosphate-glucose might alternatively be explained by the reversal of reaction (3), were it not for the fact that in the absence of uridine-tri- or di-phosphate and adenosine triphosphate[6], a condition fulfilled by the dialysed extract, this mechanism is not operating. Thus our results are in favour of the mechanism represented by reactions 1 and 2.

Table 1. INCUBATION OF ^{14}C-GLUCOSE-6-PHOSPHATE AND URIDINE-DIPHOSPHATE-GLUCOSE WITH *S. fragilis* EXTRACT

Incubation at 37° C. of 0·33 μ*M* of ^{14}C-glucose-6-phosphate of specific activity 5,910 counts/min./μ*M*, 0·01 μ*M* of glucose-1,6-diphosphate, 0·3 μ*M* of uridine-diphosphate-glucose and 2 μ*M* of magnesium ions with 0·01 ml. of dialysed *S. fragilis* extract

Mixture	Incubation time (min.)	Spec. activity UDPG glucose counts/min./μ*M*	$\dfrac{\text{Spec. activity UDPG glucose (exp.)}}{\text{Spec. activity glucose-6-phosphate equilibrated with UDPG (calc.)}}$
Without uridine-diphosphate-glucose*	30	290	0·09
Complete	30	2,910	0·96
Complete	60	2,400	0·81

* UDPG added after the enzyme was inactivated

On the basis of the exchange experiment, a procedure was developed for the preparation of the equilibrium mixture of uridine-diphosphate-glucose and uridine-diphosphate-galactose with its hexose moieties uniformly labelled with carbon-14. As hexokinase is present in the *S. fragilis* extract, ^{14}C-glucose-6-phosphate could be replaced by ^{14}C-glucose and adenosine triphosphate. The equilibrium mixture was separated by chromatography on Whatman No. 3 filter paper using ethanol – ammonium acetate as developer, and was eluted with distilled water from the corresponding area and rechromatographed with methanol – formic acid[7]. When this rechromatographed product was chromatographed with ethanol – ammonium acetate, it gave only one spot showing absorption in the ultra-violet and radioactivity.

I am indebted to the Comisión Nacional de la Energia Atómica of the Argentine Republic and to Dr. W. Z. Hassid from the University of California for the provision of ^{14}C-glucose used in this work. I am especially indebted to Dr. L. F. Leloir for his continuous support of this work, and to Drs. C. E. Cardini, A. C. Paladini, H. G. Pontis Videla and J. L. Reissig for their helpful criticism.

This investigation was supported in part by a research grant (*G*-3442) from the National Institutes of Health, United States Public Health Service, and by the Rockefeller Foundation.

Alternate Pathways of Glycerol Oxidation in *Acetobacter suboxydans*

A PREVIOUS publication from this laboratory[1] has reported in detail the rapid oxidation of glycerol to dihydroxyacetone by resting whole cells of *A. suboxydans* 621, at *p*H 6·0. This conversion proceeds more slowly beyond the dihydroxyacetone stage. In cell-free extracts with triphenyltetrazolium chloride as the electron acceptor, glycerol is oxidized at a rate comparable to the oxidation of dihydroxyacetone, with the *p*H optimum about 8·5. This contrasting behaviour has been found to be due to the presence of two major oxidative routes for glycerol oxidation, one phosphorylative, the other independent of phosphate, as shown in Table 1. With cell-free extracts at *p*H 8·5, adenosine triphosphate is obligatory (in kinase systems) not only for the oxidation of glycerol but also for dihydroxyacetone, glucose, ribose or erythritol.

The pathway of dihydroxyacetone oxidation has been examined further, and found to possess the characteristics common to the Horecker pentose cycle[2], as follows: (1) Formation of dihydroxyacetone phosphate must first take place, either from glycerol-α-phosphate or from dihydroxyacetone plus adenosine triphosphate[3]. (2) Dihydroxyacetone phosphate is then converted through isomerase and aldolase to fructose diphosphate. (3) The latter loses one mole of phosphorus in the presence of magnesium to yield an acid-stable phosphate, presumably fructose-6-phosphate. (4) The latter reaches equilibrium with glucose-6-phosphate as measured by the resorcinol test[4] in the reverse reaction; (5) either of these compounds, when added, is oxidized by triphenyltetrazolium chloride and either tri- or di-phosphopyridine nucleotide to a material that gives a positive orcinol-pentose reaction. (6) Ribose-5-phosphate is converted non-oxidatively to sedoheptulose, triose and hexose derivatives in the amounts given in Table 2. The oxidative cycle is thus closed, with an expected *R.Q.* of 1·0 for dissimilation of dihydroxyacetone. This *R.Q.* has been obtained both in resting cells[1] and in the present cell-free extract.

Table 1. PHOSPHORYLATIVE AND NON-PHOSPHORYLATIVE OXIDATION OF GLYCEROL

ATP	Q_{O_2}					
	*p*H 6·0			*p*H 8·5		
	Whole cells	Cell free extract*		Whole cells	Cell-free extract*	
	Oxygen	Oxygen	Triphenyltetrazolium chloride	Oxygen	Oxygen	Triphenyltetrazolium chloride
–	10	22	0	0·6	0	0
+	10	23	0	0·6	12	9

* Cell-free extract; total soluble fraction, prepared as described previously (ref. 11).

Each Warburg vessel contained 50 μmol. malate buffer at *p*H 6·0 or 100 μmol. tris(hydroxymethyl) aminomethane (tris) at *p*H 8·5, 5 μmol. magnesium chloride, 0·2 ml. 20 per cent potassium hydroxide in the centre well. Concentration of adenosine triphosphate was 1 μmol./ml. wherever used. The whole-cell experiments contained in addition 40 μmol. glycerol, 10 mgm. cells (dry weight) and water to 3 ml. 3 μmol. diphosphopyridine nucleotide was added together with adenosine triphosphate at *p*H 8·5. The cell-free extract experiments with oxygen had 30 μmol. glycerol, 20 μmol. sodium fluoride, and 1 ml. cell-free extract in a total volume of 2 ml. The atmosphere was air. The tubes in the triphenyltetrazolium chloride experiments were incubated *in vacuo* with 5 μmol. glycerol, 50 μmol. tris, 10 μmol. sodium fluoride, 2·5 μmol. magnesium chloride, 5 μmol triphenyltetrazolium chloride, 0·1 μmol. diphosphopyridine nucleotide and 0·1 ml. cell-free extract in a total volume of 1 ml.

Q_{O_2} for whole cells = μatoms oxygen/mgm. dry cells/hr.; for cell-free extract = μatoms oxygen, or μmol. triphenyltetrazolium chloride/ml. cell-free extract (27 mgm. dry weight, 18 mgm. protein)/hr. Time intervals used to compute Q_{O_2} (usually 20–40 min.) were sufficient to permit conversion of up to 20 per cent of the added glycerol to dihydroxyacetone.

The pentose cycle thus appears to operate *in toto* in at least one microbial system, as well as in animal tissues[6] and plants[7]. Additional presumptive evidence for its presence in yeast[8] and *Escherichia coli*[3,9] is available, and preliminary observations in this laboratory indicate that this group of reactions may function in wheat smut fungi and pea aphids[10]. In

Table 2. NON-OXIDATIVE BREAKDOWN OF RIBOSE-5-PHOSPHATE BY CELL-FREE EXTRACT

Time (min.)	0	2	5	20	30
Sugar	μmoles sugar

Hexose	0·0	0·0	1·1	2·6	4·7
Sedoheptulose	0·0	0·4	0·7	0·9	0·6
Triose-phosphate	0·0	0·5	0·6	0·6	0·8
Total*	10·0	9·8	10·0	9·1	7·8

* Values for total sugars are given as pentose equivalents (μmol. carbon/5).

The tubes were incubated *in vacuo* with 10 μmol. ribose-5-phosphate, 100 μmol. tris buffer at *p*H 8·0, 20 μmol. sodium fluoride, 0·15 ml. cell-free extract and water to 2 ml. The reaction was stopped by adding 1·6 ml. of 10 per cent trichloroacetic acid. Pentose was assayed in the reaction mixtures according to Mejbaum (ref. 12), hexose and sedoheptulose with the sulphuric acid–cysteine reaction (ref. 7), and triose-phosphate as alkali-hydrolysable phosphate. Magnesium was omitted.

Acetobacter, however, the cycle is overshadowed during growth by the non-phosphorylative oxidation described above, which accumulates dihydroxyacetone more rapidly than it can be metabolized. Details of these and related oxidations in this organism will be presented elsewhere.

This work was supported by grants from the Nutrition Foundation, Inc., the Rockefeller Foundation, and the Division of Research Grants and Fellowships, National Institutes of Health, U.S. Public Health Service.

Mechanism of the Formation of Red Melanin in the Silkworm

THE body-fluid of a mutant of the silkworm called 'Aka-Aka' (*rb*), which was discovered by me[1], turns red when exposed in the air, and the abnormal colouring of this mutant was supposed to be due to abnormal accumulation of 3-hydroxykynurenine[2]. I have recently investigated the mechanism of formation of this red colouring material.

Investigation by absorption spectroscopy and the relation of the decolorization to the reduction of the red colouring material proved that it was not a hallachrome, which is a red substance derived from tyrosine. Stepwise investigation of ultra-violet absorption spectra of the *rb* body-fluid during the course of the change of colour indicated that the absorptions at 270 mμ and 370 mμ which are characteristic of 3-hydroxykynurenine decreased and the whole absorption curve came to show the characteristics of melanin. Quantitative determinations of 3-hydroxykynurenine in the same samples by the diazo-oxide method[3] also indicated that the decrease of 3-hydroxykynurenine was parallel with the increase of red pigment.

The amounts of 3-hydroxykynurenine in the body-fluid obtained by crossing, for example, in *rb*/*rb* and +/+, were found to be 880 and 38 γ/c.c. respectively.

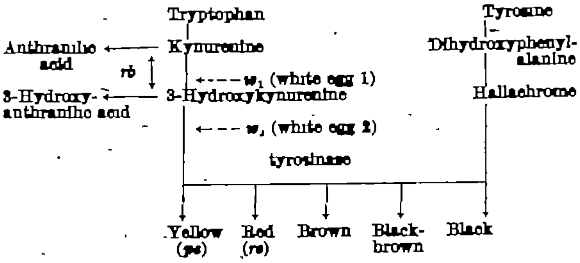
From the above facts, it will be clear that the body-fluid of silkworms turns red as 3-hydroxykynurenine accumulates in it, whereas it turns black if the amount of kynurenine is small. This conclusion was also affirmed by an *in vitro* test, in which the normal type body-fluid turned black when exposed to air; it turned red when 3-hydroxykynurenine was added.

Following up this idea, I have prepared melanin dyes of various colours from dihydroxyphenylalanine, 3-hydroxykynurenine and tyrosinase (potato) as follows:

Dihydroxyphenylalanine	3-Hydroxykynurenine	Tyrosinase	Colour	Precipitation
+	–	+	black	+++
2 mol.	1 mol.	+	black-brown	++
1 mol.	1 mol.	+	red-brown	+
0·5 mol.	1 mol.	+	red	±
0·25 mol.	1 mol.	+	red	–
—	+	+	yellow	–

While the increase of dihydroxyphenylalanine resulted in a black colour, 3-hydroxykynurenine produced a reddish colour.

Thus the mechanism of the formation of colouring materials in silkworm could be explained according to the following scheme, and the same mechanism can be applied to the formation of egg colour in the mutants called 'pink egg' (*pe*) and 'red egg' (*re*).



The absorption spectra were kindly measured by Dr. K. Ueno, of Dojindo and Co., Ltd.

Primycin, a New Antibiotic

FROM the intestinal tract and the fæces of a strain of the larvæ of the wax moth (*Galeria melonella*), a micro-organism producing an antibiotic has been isolated. Morphologically, it belongs to the *Actinomycetes*, grows readily and spores abundantly on slightly alkaline nutrient agar, potato agar and asparagine agar, with an optimal yield of the antibiotic in a liquid medium containing 2–4 per cent corn-steep liquor and 1 per cent glucose. At 37° C. a surface culture on the latter medium begins to produce the antibiotic on the third day, with a maximal yield from the sixth to the ninth days. During growth the initial pH 7·4–7·6 of the medium rises to 8–8·5, accompanied by a steady decrease of carbohydrate and nitrogen concentration. At the peak of production a rapid lysis of mycelium takes place; but on further incubation the antibiotic concentration of the medium is not reduced.

The growth of *Staph. aureus* D. in a medium containing 5 ml. casein hydrolysate is inhibited by 0·01–0·03 ml. of the samples taken from surface cultures six to eight days old, diluted 1 to 10. Submerged cultures give an average yield somewhat below this level. On acidifying the filtrate of fermentation fluid (*p*H 2·5–2·8), a voluminous precipitate is formed which adsorbs the active substance to its surface almost quantitatively. The precipitate may be dried without loss of activity; its aqueous suspension is active at concentrations of 3–20 μgm. per ml. The substance is thermostable. The crude product contains 8–10 per cent ash, lipids and other organic substances, nitrogen 10–12 per cent, which can be removed by ether extraction. The active substance may be transferred quantitatively from the extraction residue to dry methanol, together with considerable pigment and inorganic phosphate impurities, which can be adsorbed with colloidal aluminium hydroxide. The active substance can be separated by adding ether to this partly purified and concentrated methanol solution. Solutions of this crude product inhibit the growth of *Staphylococcus aureus* D. in concentrations of 0·1–0·3 μgm. per ml. This crude product contains 5–32 per cent ash and 1·6–3·5 per cent nitrogen.

Further purification of this crude preparation was carried out by dissolving the precipitate in 20 per cent methanol and extracting this mixture repeatedly with butanol. The active substance was prepared by precipitation of the collected butanol extracts with ether. The effectiveness of the substance on this level of purity corresponds to 0·05–0·07 μgm./ml. By repeating this treatment further purification of the substance may be obtained, but the preparation still contains pigments in small amounts and 0·0–0·4 per cent ash. The active substance ('primycin') forms white micro-crystals when crystallized from methanol–butanol and melts at 166–168° C. with decomposition; analysis: C, 58·79; H, 9·56; N, 3·63 (Dumas); N, 3·58 per cent (Kjeldahl). These results correspond with the empirical formula $C_{19}H_{37}O_7N$, giving a molecular weight of 391·5. Ebullioscopic determination of molecular weight gave 329·9 (in methanol). The active substance has no characteristic absorption maximum either in the visible or in the ultra-violet region.

Primycin is fairly soluble in methanol (2·5 per cent), less soluble in higher alcohol homologues, sparingly soluble in pyridine, glacial acetic acid and water (50 mgm. per cent) and insoluble in other solvents. Its aqueous solution is sensitive to electrolytes, thermostable, strongly surface-active and adsorptive. In concentrated sulphuric acid it dissolves, giving first a yellow, then a red colour. It does not reduce Fehling's solution, does not react with aldehyde reagents and gives the Brunner–Pettenkoffer reaction. In a pyridine medium it can be acetylated. The acetylated (in pyridine) substance is inactive, but regains full activity after splitting off the acyl groups. Solutions of the purest product obtained so far inhibit the growth of *Staph. aureus* Duncan in concentrations of 0·02–0·06 μgm. per ml. It has *in vitro* a bacteriostatic effect on Gram-positive organisms, both pathogenic and non-pathogenic, as well as on Mycobacteria. In this order of magnitude it affects resistant strains too. The presence of serum reduces its potency to a quarter to a fifth of the initial potency. Its activity is increased at alkaline and reduced at acid reaction, with an optimal *p*H in the range 7·6–7·8. *In vitro* it is non-toxic to tissue cultures. So far as can be judged at present, it has also viricidal effects. Toxicity: *LD* mice, 2·5 mgm./kgm.; *LD* rats, 10 mgm./kgm.; *DT* rabbits, 10 mgm./kgm. In the rabbit a dose of 5 mgm./kgm. intraperitoneally is still detectable in the serum six hours after administration. Since in animal experiments it appeared to be toxic, only superficial infections of man have been treated with it, but good results have been obtained. On the basis of its chemical and biological properties, primycin is not identical with any of the known antibiotics.

A detailed account of this investigation is to be published elsewhere.

Adrenocorticotrophic Activity of Melanophore-expanding Hormone Preparations from Beef Pituitary Glands

Since it has been claimed recently that adrenocorticotrophic hormone and melanophore-expanding hormone are identical, we assayed several melanophore-expanding hormone preparations from beef pituitary glands for adrenocorticotrophic activity.

The assays were performed according to a modification of the procedure of Saffran *et al.*[1] on melanophore-expanding hormone preparations of different potencies (respectively 25, 75 and 150 times standard posterior pituitary powder) which were prepared by Stehle[2] (we are indebted to Prof. R. L. Stehle for putting his preparations at our disposal). These preparations were found to possess relatively little adrenocorticotrophic activity, but there is a correlation between the two activities.

Preparation	Melanophore-expanding potency (I.U./(mgm.)	Adrenocorticotrophic potency (I.U / mgm.)	Range of adrenocorticotrophic potency (I.U./mgm.)	Ratio of melanophore-expanding to adrenocorticotrophic potency
1	50	0·024	0·015–0·039	2,080
2	150	0·065	0·034–0·126	2,310
3	300	0·167	0·106–0·241	1,800

The table lists the melanophore-expanding and adrenocorticotrophic activities of three melanophore-expanding hormone preparations. Preparation 1 was used as the starting material for preparation 2, which, in turn, was used to prepare 3. At the three stages of purification of the melanophore-expanding hormone, the ratio adrenocorticotrophic and melanophore-expanding activity remains essentially constant.

Our results show that potent preparations of melanophore-expanding hormone contain only traces of adrenocorticotrophic activity, so that it is impossible to conclude that melanophore-expanding and adrenocorticotrophic activities are entirely shared by the same molecule. The constancy of the ratio of the adrenocorticotrophic potency to the melanophore-expanding activity upon purification does not rule out the possibility that adrenocorticotrophic hormone is present as an impurity in the melanophore-expanding hormone preparation, but it also strongly suggests that melanophore-expanding hormone may possess some slight inherent adrenocorticotrophic activity.

Salicyloylhydrazide: a Reagent of Wide Use in Organic and Histochemical Analysis

Present methods of demonstrating ketosteroids in tissues are generally regarded as being unsatisfactory. 2-Hydroxy-3-naphthoyl hydrazide[1] is the reagent most recently introduced for this purpose, yet it condenses only sluggishly with carbonyl groups and fails to distinguish between aldehydes and ketones. A number of phenolic hydrazides have since been tested. Of these, 2 : 4 dihydroxybenzoylhydrazide[2] is better in that it provides azo-hydrazones of different colours in the ketosteroid group[3], but it still lacks adequate condensing reactivity.

Salicyloylhydrazide[4] is at present under investigation, and the preliminary results now reported may prove of interest to workers both in histochemistry and in other fields. It has been found that the aldehydic salicyloylhydrazones fluoresce brilliantly in diverse colours under ultra-violet light, whereas the ketonic derivatives which have been studied exhibit a uniform dull blue fluorescence. Zinc acetate greatly intensifies the ketonic fluorescence, but has no appreciable effect on the fluorescence of the aldehydic derivatives. A similar but very much weaker reaction is obtained with cadmium salts. Neither the reagent nor the carbonyl compound separately shows any luminescence at low *p*H.

The colour and intensity of fluorescence of the salicyloylhydrazones may be further controlled in two fundamental ways: (1) chemically, by alteration of *p*H, by treatment with free halogens, and by chelation; and (2) optically, by using an instrument capable of offering a series of monochromatic beams of ultra-violet light of differing wave-lengths. Preliminary experiments, utilizing varying combinations of these two control procedures, indicate that it may be possible to devise a system capable of distinguishing individual components of a mixture of ketones.

Investigations have also been carried out to determine quantitatively the condensing reactivity of the reagent. In a typical experiment, dehydroepiandrosterone was condensed with salicyloylhydrazide in acetic acid solution and excess reagent removed by washing with dilute hydrochloric acid. The salicyloylhydrazone, in virtue of its being a phenol, was then converted to an indoaniline by coupling it with *p*-aminodiethylaniline (stabilized with sulphur dioxide), in the presence of periodic acid as oxidant. The intensely coloured blue-green indoaniline was extracted with ethyl acetate and the optical density read in an absorptiometer against a blank determination, using a suitable filter. A linear relation was found between the optical density and the amount of ketosteroid present over the range 5–50 μgm.

Quantitative estimation of ketosteroids by fluorimetry of the salicyloylhydrazones is being studied in order to achieve an analytical method of a more direct and simple character.

Although salicyloylhydrazide has been investigated in the first instance as a reagent for use in histochemistry, the indoaniline reaction for phenols and also the fluorescent reaction of zinc acetate with salicyloylhydrazones are obviously capable of much wider application.

In general, salicyloylhydrazide is superior to the previous hydrazides I have described[1,2] in respect of reactivity in condensation, in differentiating capacity and in lending itself to colorimetric determination of ketosteroids.

The detailed use of the foregoing procedures in histochemistry and in relation to the estimation of ketosteroids will be the subject of future communications.

I am grateful to Prof. J. Patterson for his guidance throughout and to Prof. R. J. Harrison and Dr. G. H. Bourne for histochemical facilities provided at the London Hospital Medical School. The optical experiments were carried out at the National Institute for Medical Research in conjunction with Mr. J. Smiles, to whom I am indebted for the special knowledge and advice he contributed.

Lingual Proprioception in Pig, Dog and Cat

The muscle-spindles, shown by Cooper[1] to exist in the intrinsic tongue muscles of man and rhesus monkey, have not so far been satisfactorily demonstrated in other species.

Cooper has failed to find proprioceptive end-organs in the intrinsic musculature of the tongue in lamb and kitten, and this finding has been confirmed and extended by a histological survey of mammalian tongues in the course of this work.

However, the pattern of innervation in the tongues of pig, dog and cat suggests that proprioceptive impulses in these animals may be, at least in part, conveyed through a certain specialized form of receptor found in the intramuscular connective tissue, which is sufficiently constant in all three species to justify further attention.

Thick frozen sections, prepared by the diammine-silver ion method of Garven and Gairns[2], show that these end-organs are formed by a coil of axis-cylinder enclosed in an oval or pear-shaped capsule, which appears to be a terminal dilation of the neurilemma. The long axis of the capsule lies parallel to that of the muscle fibres. The endings occur mainly in the intrinsic muscles and are most abundant between the vertical and transverse groups, where they are closely associated with the strata of motor innervation in this region. A few endings were found in the inferior longitudinal muscle; none was noted in the superior longitudinal.

The structure and position of the intramuscular endings suggest that deformation of the capsule resulting from muscular activity, may initiate low-threshold stimuli of a proprioceptive nature.

While histological evidence points to the derivation of the nerve-endings from fibres of the hypoglossal, it must be remembered that no conclusive evidence has been produced regarding an afferent component in this nerve. Boyd[3] alludes to the presence of Froriep's ganglion in the pig; but our examination of the hypoglossal in six infant pigs failed to reveal sensory cells on its intra- or extra-cranial fibres. This may be due to the general inconstancy of the ganglion, or to the immaturity of the subjects, and will require further investigation. In two of the animals, a well-marked group of sensory cells was noted on the extra-medullary fibres of the eleventh cranial nerve.

The function of tactile receptors in the regulation of tongue position must also be considered. In the animals examined, well-developed end-organs in the form of modified Meissner corpuscles were numerous in the dorsal mucosa of the posterior third of the tongue, and a few of similar character were observed near the tip.

It is perhaps significant that in the middle third of the tongue, where intramuscular connective tissue endings are most evident, no tactile corpuscles could be identified.

The investigation of lingual proprioception in mammals is being further pursued, the work being assisted by a grant from the Medical Research Council of Ireland.

Presence of Zinc in Nucleoli and its Possible Role in Mitosis

The nucleolus is now believed to be composed mainly of ribonucleoproteins (Caspersson[1], Brachet[2]), although Vincent[3], who succeeded in isolating large quantities of nucleoli from starfish oocytes, concluded that the bulk of the nucleolus is phosphoprotein. On the other hand, Jacobson and Webb[4], like Zirkle[5] before them, indicated that some nucleolar substances (ribonucleoproteins) are contributed to the chromosomes during the mitotic cycle. Doubt exists, however, as to whether it is correct to regard ribonucleic acid and proteins as the only constituents that are important. We may suspect that other nucleolar substances which are less obvious play important parts in mitosis.

In a forthcoming paper, it has been shown[6] that zinc is found in considerable amount in the nucleoli of starfish oocytes. When the suspension of isolated nucleoli of the starfish oocyte, *Astropecten scoparius*, was allowed to stand with a small amount of 6 mgm./100 ml. dithizone solution in carbon tetrachloride for several hours, a deep-red colour was produced in the latter layer. This suggested that complex formation was occurring between zinc and this reagent within nucleoli. The proof that zinc is responsible for this dithizone reaction came from observations on polarograms. When the ash of the isolated nucleoli was analysed polarographically in the presence of zinc-free sodium acetate (pH 4·8), it gave a wave with a half-wave potential at − 1·05 V., suggesting that zinc was obviously reacting.

We have now proceeded some way with the analysis of the behaviour of the zinc during the mitotic cycle. It was found that when a small quantity of a saturated solution of diphenylthiocarbazone (dithizone) in 60 per cent alcohol, which was diluted with an equal volume of a borate buffer (pH 8·4), was added to the fertilized sea-urchin eggs, *Clypeaster japonicus*, on the slide, a purple colour was instantly developed within the nucleoli. The nucleoli of other forms, such as starfish oocytes and the staminal hair cells of *Tradescantia*, also stained purple, in marked contrast to the nearly colourless nuclear substance and cytoplasm.

We have further found that if sea-urchin eggs are treated with a small amount of alcoholic dithizone, mitosis proceeds practically normally, and the fate of the purple-staining substance can be traced throughout the mitotic sequence. It was found that the whole spindle first appeared faintly purple at about the time when the nucleolus disappeared (late prophase or prometaphase). The chromosomes were also seen to stain purple within the spindle. Whether spindle fibres were stained cannot be stated, although purple striations were often observed. It is interesting that the living spindle is clearly visible under these conditions. At metaphase, when the chromosomes were gathered at the equator of the spindle, they stained most deeply and appeared in greater relief under the ordinary microscope. They remained so during anaphase and gradually lost their purple-staining component as they swelled in telophase. It was possible to follow the movement of the faintly stained masses of chromosomes as they were incorporated into daughter nuclei. It appeared that the staining substance was then transferred from the chromosomes into the nuclear sap and finally consolidated into the nucleoli. It is of special interest to observe that the spindle as a whole became suddenly colourless at the beginning of anaphase, though in the final telophase some purple striations reappeared in the spindle region. Whether the centres or the centrioles stain cannot be decided. Since, however, the middle-piece and acrosome of the sperm were also found to be dithizone-positive (Fujii[6]), it is likely that the centres contain zinc. No evidence was found that asters are dithizone-positive.

These observations on the behaviour of nucleolar substance during mitosis are, of course, open to objections, since the dithizone reaction is not very specific and the chromosomes are too small to draw any definite conclusions. But the evidence so far obtained suggests that zinc is present in nucleoli and that, upon the initiation of mitosis, it passes into the chromosomes and possibly also into the prometaphase spindle.

Lastly, we may suggest that the behaviour of the zinc is related in some way to the reversible denaturation of active proteins, which might be involved in the physical changes of chromosomes and of the spindle during mitosis, for we are obtaining evidence that a parallel exists between the unmasking of —SH groups and the release of zinc from some tissues. It is likely that zinc is only released in catalytic quantities from nucleoli or from chromosomes, and is acting as what Swann[7] calls a 'structural agent'. Structural changes of chromosomes during mitosis, which are interpreted by Kuwada[8] as due to hydration and dehydration, may also be explained by this hypothesis.

Stability in Development and Relational Balance of X-Chromosomes in *Drosophila melanogaster*

Mather[1] has shown that asymmetry of sternopleural chaeta number in *Drosophila melanogaster* is subject to genetically controlled variation and is a valid measure of the capacity of the genotype to promote stabilization or canalization of the development of the individual. The following results show effects on asymmetry of X-chromosomes extracted from four different experimental populations.

Two of these populations have been maintained at a constant 25° C. and the other two have spent each day at 25° C. and each night at 15° C. (For the present purpose, however, these should merely be regarded as two different environments, for their mean temperatures are different and there is no check that any difference due to environments arises from the fluctuation in temperature rather than the mean.) The populations were all started at the same time from a combination of the same two laboratory stocks, one homozygous for w^e and the other for w. (The effects of selection on this locus have already been reported[2].)

After the populations had been maintained for sixteen months, w^e males were extracted from each of them and mated to Muller-5 females. The X-chromosomes from these males were then maintained by continually backcrossing the heterozygous w^e/Muller-5 females to stock Muller-5 males. It had been intended to control chromosomes II and III using balancers, but the appropriate crosses gave difficulty so that backcrossing was relied on to give reasonably uniform genetic backgrounds. After five generations of backcrossing, the X-chromosomes were tested by matings that would produce females homozygous for a particular X-chromosome (H flies), matings that would produce females heterozygous for X-chromosomes from the same population (intra-population heterozygotes: I flies) and matings that would produce females heterozygous for X-chromosomes from different populations that had been maintained in the same environment (extra-population heterozygotes: E flies). The experiment involved replicate cultures (apart from failures), three chromosomes from each population, and each chromosome or combination was tested in each of the two environments. The experiment was repeated after a further generation of backcrossing. Ten w^e/w^e females were counted from each culture, and the sum of their arithmetical asymmetries was used as the datum for analysis. (It should be noted that the measure of asymmetry used for this preliminary report differs from that used by Mather.)

Table 1

Type of female	Environment of test culture	Environment of population from which X-chromosomes were extracted 25° C.	Fluctuating	Total
Homozygotes (H)	Home Foreign	189 221	174 230	363 451
	Total	410	404	814
Intra-population heterozygotes (I)	Home Foreign	194 162	157 180	351 342
	Total	356	337	693
Extra-population heterozygotes (E)	Home Foreign	236 224	230 218	466 442
	Total	460	448	908
	Total, Home „ Foreign	619 607	561 628	1,180 1,235
	Total	1,226	1,189	2,415

Table 2

Source	Sum of squares	n	Mean square	Correct F	p
Type of fly (HIE)	242·0208	2	121·01	26·06	<0·001
Env of population (EP)	4·7535	1	4·75	1·02	—
Env of test culture (EC)	10·6028	1	10·60	2·26	>0·05
HIE × EP	0·8820	2	0·44	—	—
HIE × EC	70·6534	2	35·33	7·61	<0·001
EP × EC	21·6706	1	21·67	4·67	<0·05
HIE × EP × EC	22·1938	2	11·10	2·39	>0·05
Repetitions	12·0868	1	12·09	2·71	>0·05
Residual* (error)	1,106·4549	238	4·64		
Total	1,490·2188	250†			

* Differences between cultures (that is, within chromosomes) give a slightly larger mean square than all other residual differences combined. Hence a combined error is used.

† Of the 288 cultures, 37 failed.

Table 1 gives the pooled results, the environments of the test cultures being classified into 'home' (the same as that of the population from which the tested X was obtained) and 'foreign'. Table 2 gives the results of analysis of variance of the 288 culture results. There are two highly significant items, the HIE comparison and the interaction HIE by culture environment.

All three items involved in the HIE comparison are significantly different from one another. (This variation of asymmetry is not a result of variation of mean bristle number. The mean bristle numbers per fly are H 16·2335, I 16·2296 and E 16·2069.) The significant interaction arises because the homozygotes are specifically adapted to the 'home' environment, whereas I heterozygotes are as well-adapted to either environment as are homozygotes to the 'home' environment and E heterozygotes are as ill-adapted to either environment as the homozygotes to the 'foreign' environment.

We may assign 1 as a measure of the stability of homozygotes in their 'home' environment and 0 as a measure of their stability in the 'foreign' environment. The significant differences and the similarities can then be summarized as follows:

Type of fly	Culture environment Home	Foreign	Total
Homozygotes	1	0	1
Intra-population heterozygotes	1	1	2
Extra-population heterozygotes	0	0	0

A number of points emerge:

(1) The homozygotes are as stable in development as any other type in the home environment. This stability presumably depends upon an internal balance[3] and is not surprising since, if the X-chromosome is to contribute to stability, it must operate in the hemizygous male as well as in the female.

(2) The intra-populational heterozygotes are equally stable in the foreign environment (they are phenotypically flexible in the sense of Thoday[4], or homeostatic in the sense of Dobzhansky and Wallace[5]). Their stability in the foreign environment does not depend upon their internal balance since it is not reproduced by the homozygotes. Neither does it depend on some virtue of heterozygosity *per se* as Robertson and Reeve[6] have suggested, for it does not extend to the extra-populational heterozygotes. It clearly depends on the fact that the chromosomes contained in the heterozygotes have evolved in relation to one another through the operation of natural selection in a single population of outbreeding organisms producing relational balance in Mather's sense[3].

(3) Despite the fact that both the chromosomes involved have internal balances conferring stability to the same environment, the extra-population heterozygotes are unbalanced in the home environment: in this environment they show negative heterosis, underlining the conclusion that positive heterosis depends upon relational balance. These E heterozygotes are also no better than the homozygotes in the foreign environment, though no doubt some environment might be found in which the homozygotes are inferior.

Contemporary genetical research is rapidly producing example after example in which heterozygotes are proving to have smaller non-genetic variances than have corresponding homozygotes, and there is a danger that it may be concluded that heterozygosity necessarily promotes homeostasis. The present results indicate that, sometimes at least, relational balance is necessary, and that some homozygotes can be superior to comparatively unbalanced heterozygotes.

Mather (ref. 1, pp. 330, 331) has already discussed the relationship between selection, breeding system and stability of development and suggested that superior stability of heterozygotes is less likely in naturally inbreeding organisms. The present results provide an illustration of a similar principle.

Liberation of Amino-acids by Plant Roots in relation to Desiccation

PREVIOUS reports from this laboratory[1–3] have shown that in the rhizosphere, or zone of influence of the roots of growing plants, there is a preferential stimulation of bacteria requiring amino-acids for maximum growth. This communication concerns the production of amino-acids by roots of several kinds of plants in an attempt to explain, at least in part, the preferential effect noted on this group of organisms.

Although frequent mention is made of excretion of organic substances by roots, there is surprisingly little information as to the extent of such excretion or the nature of the substances liberated. There is certainly very little evidence of excretion of amino-acids by roots of non-legumes, although Kandler[4] has reported recently the liberation of amino-acids by excised roots of maize. The production of certain specific amino-acids by roots of legumes, as shown by Virtanen and his group, may be considered a special case, since it involves a symbiotic relationship with the nodule bacteria. It may be postulated that amino-acids are produced in the rhizosphere in amounts which would permit growth of amino-acid-requiring bacteria, by a number of agencies only one of which may be excretion from intact roots. They may also be liberated from sloughed-off root caps, root hairs or epidermal cells and by the decomposition of these root fragments, and of microbial protoplasm. In addition, they may arise through microbial synthesis, for there is some evidence that bacteria with simple nutritional requirements, also stimulated in the rhizosphere, liberate amino-acids which can be used by the amino-acid-requiring bacteria[5]. Preliminary experiments with six- to eight-week-old soybean, tomato and wheat plants showed that these could absorb known amino-acids through their leaves and that these acids were recoverable in the dilute mineral solution in which the roots were immersed. It was also noted that even roots of control plants, not fed amino-acids, contributed variable, though small, amounts of ninhydrin-positive substances to the mineral solution. When such roots were allowed to dry and then remoistened, a striking increase in amino-acids was observed. In normal field conditions, plant roots are subjected to desiccation and remoistening. In the light of the above observation, this may contribute significant amounts of amino-acids for the rhizosphere microflora and thus account in part for the preferential stimulation of amino-acid-requiring bacteria.

Further data on the nature of the amino-acids liberated and the extent of such production were obtained from plants grown in thoroughly washed sand moistened with a suitable mineral solution. After these plants were six to eight weeks old, the pots were divided into two lots, one of which was allowed to dry out and the other kept moistened. When the sand was dry and the plants showed signs of wilting, all pots were brought up to their original weight, and after one hour leached with water; 200 ml. was collected from each pot and the leach water filtered through paper. One portion was concentrated *in vacuo* for chromatographic and total amino-nitrogen analysis, and the remainder dispensed into test-tubes and sterilized after the addition of 0·1 per cent glucose. These tubes were inoculated with selected amino-acid-requiring bacteria. The results of amino-nitrogen analysis by heating with ninhydrin[7] and determining the intensity of the resulting colour at 540 mμ in a Klett–Summerson photoelectric colorimeter are given in Table 1. It is clear that appreciable amino-nitrogen was elaborated in sand which was dried and remoistened in the presence of the plant root system, but not in sand, treated similarly, after the plants had been removed. These results were confirmed by means of paper chromatography, which showed a variety of amino-acids in the leach water of treatment 2, including glutamic and aspartic acids, leucine, alanine, cysteine, glycine, lysine, phenylalanine and proline (isatin spray). Still further corroboration was provided by the observation that by far the best growth of the amino-acid-requiring bacteria tested occurred in the leach water of treatment 2. Similar experiments were set up with 50 per cent sand–soil mixtures with essentially similar results. Of interest, too, is the evidence of the presence of ninhydrin-reactive material in the leach waters of pots kept moist throughout the duration of the experiment, suggesting that even such plants may liberate amino-nitrogen, perhaps by sloughing off root fragments. Experiments under way with completely sterile systems indicate that small amounts of ninhydrin-positive substances are produced by roots under these conditions also.

Table 1. LIBERATION OF AMINO-ACIDS BY PLANT ROOTS

Treatment	Total amino-nitrogen* (optical density at 540 mμ)			
	Tomato	Soybean	Barley	Oats
1. Dried sand, remoistened after plants removed	5	0	0	0
2. Dried sand with plants; remoistened	67	209	193	287
3. Wet sand, after plants removed	5	10	0	2
4. Wet sand, with plants	10	10	0	2

* Average of triplicate tests

The presence of a reducing compound with an R_F value identical with that of glucose has also been observed in the leach waters (treatment 2, Table 1) of the four plants studied.

Variation of the Shells of *Murex tribulus* from the Great Bitter Lake, Egypt

On the shore of the Great Bitter Lake in the neighbourhood of Fayid, the most conspicuous member of the molluscan fauna is a gastropod which, according to the authorities at the British Museum (Natural History), belongs to the species *Murex tribulus*. The shells at once attract attention by their remarkable variability.

To the student of variation in animals, the shells are of particular importance inasmuch as the varying features are of such a nature as to facilitate accurate observation, exact measurement and reliable record. Among these features, apart from variation in size, shape and in the proportions of the various parts, the most conspicuous are the numerous blunt spines projecting from the shell and playing a main part in giving the shell its very characteristic appearance. It is these spines, too, which provide material of special importance to the student of variation.

The material for this study consists of a collection of some three hundred shells made by Sir John Graham Kerr while staying at Fayid during the early months of 1951 and 1953. The collection is now in the Science Department of the College of Notre Dame, Dowanhill, Glasgow.

The details of a typical shell are shown in Fig. 1 (upper). The spines are arranged in rows, each row corresponding to a varix, three large to each whorl of the shell. A ridge or rows of tubercles is continuous between each spine and the corresponding spine of the next whorl, those connecting the large spines being more prominent than those connecting the small ones. The body whorl of the shell is drawn out into the tapering anterior canal bearing spines, except at the extreme tip. This carries the siphon and therefore in life is lined by the mantle. Variation occurs in the length of the anterior canal between about 5 and 39 per cent of the total length of the shell, and markedly also in the length of the portion free from spines, this portion being so short in some cases as to give the shell a truncated appearance. Examination of the individual spines shows that they vary greatly—in length—from a mere tubercle up to about 12 mm., and in the angles at which they spring from the surface of the shell. Examination of a corresponding spine in the various shells showed that this angle varied between 22° and 53°.

An elaborate and detailed study of the whole collection has been carried out by Sister M. Josephine Parkes. Most regrettably, the publication of her valuable paper, illustrated by beautiful photographs by Dr. H. F. Steedman, of the Department of Zoology, University of Glasgow, has been held up for the time being.

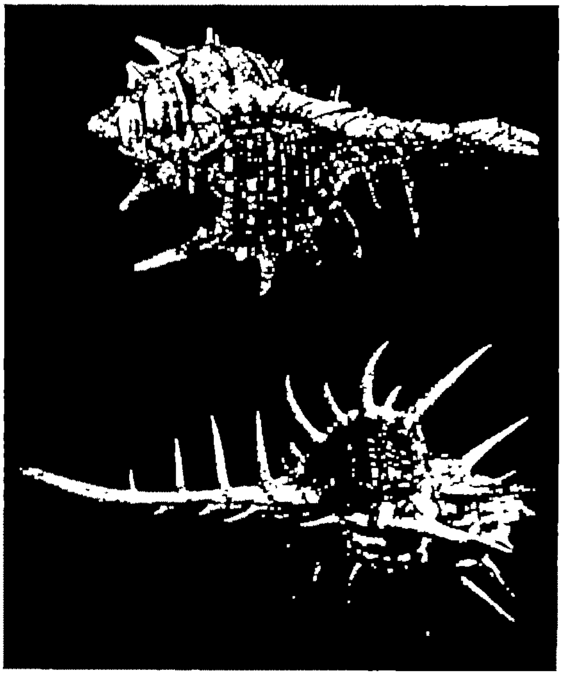

Fig. 1

The Bitter Lakes occupy part of the channel of what once formed a communication between the Red Sea and the Mediterranean. At the time of the cutting of the Suez Canal in 1869, the site of the Bitter Lakes was dry land; but the opening of the Channel into the Gulf of Suez admitted the waters of the Red Sea, and the Bitter Lakes came into being. As time went on they became colonized by immigrant organisms from the Red Sea and among these was *Murex tribulus*.

The collection and preliminary study of the shells from Fayid were made in ignorance of the Red Sea forms from which they were presumably derived. It was therefore with much interest that specimens from the Red Sea were later examined. In these the blunt spines of the specimens from the Great Bitter Lake were found to be sharply pointed, as shown in Fig. 1 (lower). This specimen came from the shallow waters between the coast and the coral reef at Hurghada. There these spines may well constitute a most effective armature against the voracious enemies among which this species lives.

I have to thank Mr. D. E. Morgan, of the Anglo-Egyptian Oilfields, Ltd., for facilitating the collection of 185 specimens from Hurghada on the west side of the Red Sea close to the opening of the Gulf of Suez, and 114 from Ras Matarma on the east side of the Gulf of Suez. To him and his colleagues and to many others who have responded to my appeal in *Nature*[1], I must extend my warmest thanks.

To the general zoologist, the facts summarized here are of great interest. *Murex tribulus* is an organism which by its perfect adaptation has been able to survive and flourish amid all the complexities and dangers incidental to the luxuriant and varied fauna inhabiting the coral reefs and their immediate neighbourhood. The Fayid specimens represent members of the species that have wandered into the placid environment of the Bitter Lakes with their comparatively sparse fauna; and the lesson they teach is how a species, freed from the shackles of the environment to which it has been through long ages adapted, gives way to the general instability of living substance and shows untrammelled variability.

A Hydropolyp in the Biological Cycle of a Freshwater Jellyfish

DURING investigations on the invertebrates of Lake Tanganyika we have been able to find all the stages of the sessile generation of the well-known Tanganyikan Trachymedusan *Limnocnida tanganyicae* Günther. We have also collected them in Lakes Mohasi and Sake (Ruanda), where the sexual reproduction seems to be more important. These hydropolyps are completely invisible when living and must be treated first with some fixative (Bouin's or Zenker's fluids); they are very minute (less than 0·5 mm. for one individual) and transparent.

Exceedingly voracious, they feed on midge larvæ. They live in quiet places (Gulf of Burton) in Lake Tanganyika, or in calm lakes (such as Mohasi or Sake). They attach themselves principally around the septa of *Phragmites* stems, and they are very often mixed with colonies of Bryozoa.

In Lake Mohasi, sexual reproduction takes place from mid-April to the beginning of September. In Lake Tanganyika it only begins at the end of May.

This finding shows that, contrary to the marine Trachymedusæ, most of the freshwater forms have a sessile sexual stage.

The complete study of this sexual generation will be published elsewhere.

"Sixth Commonwealth Entomological Conference"

IN the account in *Nature* of September 18, p. 541, of the Sixth Commonwealth Entomological Conference, I am reported as saying that the results of insecticides used against tsetse fly suggest that tsetse populations "may be unable to recover after reduction below a certain level".

My point was quite different. It was that the tsetse population might be found to maintain itself permanently at *any* level (above, of course, a low minimum) to which the insecticide had reduced it. This idea, first put forward by me in 1937 (*Proc. Zool. Soc. Lond.*, 1936, 811, Section X), is now supported by some of the findings of the East African Colonial Insecticides Research Unit (Hocking, Parr, Yeo and Anstey, *Bull. Ent. Res.*, **44**, 627; 1953), and has the greatest practical importance as, for example, when a few flies straggle back across a barrier into country from which they had previously been evicted.

C. H. N. JACKSON
(Chief Entomologist)

Central Tsetse Research Laboratory,
P.O. Shinyanga,
Tanganyika Territory.

IT is regretted that, in the attempt to convey in a few lines the gist of long and complex discussions, Dr. Jackson has inadvertently been misrepresented. The relevant passage in his paper is as follows: "To my mind, the fundamental fact arising from all this work is that isolated tsetse populations by no means always tend to recover, when applications of insecticide cease." At an earlier meeting, Dr. Jackson had indicated more precisely the point he now emphasizes, namely, that the results of insecticide experiments seem to confirm his view that the size of tsetse populations is not controlled by density-dependent factors. The discussion, however, had been principally directed to the question, which he now dismisses in a parenthesis, of whether there was a ***minimum*** size of stable population of tsetse. It was suggested that a percentage reduction of the order that can be achieved by insecticides might, with an initially small population, result in a density so low that the fly could not maintain itself, particularly—as Dr. Jackson pointed out—if the environment were then altered by settlement. It was this thought, which was evidently felt to be of the highest practical importance, that the offending sentence sought to convey.

THE WRITER OF THE ARTICLE

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, December 13

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 4 p.m.—Dr. Donald Hunter: "Lung Disease due to Dusts".*

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (in the Reynolds Hall, College of Technology, Manchester), at 5.45 p.m.—Prof J. Z. Young, F.R.S.: "Memory" (Ramsden Memorial Lecture).

INSTITUTE OF METAL FINISHING (at the Northampton Polytechnic, St. John Street, London, E.C.1), at 6.15 p.m.—Mr. H. Silman: "Recent Developments in Chromium Plating".

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE, PHILOSOPHY OF SCIENCE GROUP (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 8 p.m.—Prof. C. H. Waddington, F.R.S.: "The Philosophic Bearing of some Recent Ideas on Evolution".

Monday, December 13—Tuesday, December 14

PHYSICAL SOCIETY (in the Poynting Physics Building, The University, Birmingham)—Autumn Meeting on "A Survey of Field Theory".

Tuesday, December 14

ZOOLOGICAL SOCIETY OF LONDON (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

INSTITUTE OF PHYSICS, ELECTRONICS GROUP (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. G. W. Jull: "The Ruthemann Spectra of Electrons".

INSTITUTION OF CHEMICAL ENGINEERS (joint meeting with the CHEMICAL ENGINEERING GROUP, SOCIETY OF CHEMICAL INDUSTRY, and the INSTITUTION OF BRITISH AGRICULTURAL ENGINEERS, at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. Ewen McEwen and others: "The Drying of Wheat Grain".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Dr. F. M. Lea: "Experimental Science and Civil Engineering Research" (Unwin Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENTS SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. G. W. Bowdler: "An Attracted-Disc Absolute Voltmeter"; Mr. M. H. Halne and Mr. M. W. Jervis: "The Use of an Electron Velocity Analyser to Stabilize a 50 kV. D.C. Voltage Source to a Few Parts in a Million"; Mr. M. W. Jervis: "A Precision Direct-Current Stabilizer".

INSTITUTION OF THE RUBBER INDUSTRY (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. S. Mottram: "Compounding the Vinyl Polymers". 7 p.m.—Dr. F. M. Merrett and Mr. R. I. Wood: "Polymer-modified Natural Rubber".

Tuesday, December 14—Wednesday, December 15

NATIONAL INSTITUTE OF AGRICULTURAL BOTANY (at the Cambridge Union Society, Bridge Street, Cambridge)—Third Crop Conference—"Crops for Home Feeding".

Wednesday, December 15

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Prof. A. Wormall: "Isotopes in Medical Investigation".*

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. H. G. Reading: "The Stratigraphy and Structure of the Cotherstone (Stainmore) Syncline"; Dr. D. A. Robson: "A Sedimentary Study of the Fell Sandstones of the Coquet Valley, Northumberland".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, South Kensington, London, S.W.7), at 5 p.m.—Scientific Papers.*

ROYAL SOCIETY OF MEDICINE, COMPARATIVE MEDICINE SECTION (at 1 Wimpole Street, London, W.1), at 5 p.m.—Discussion on "The Ecology of Some Arthropod-borne Diseases of Man and Animals". Opening Speakers: Prof. P. A. Buxton and Prof. G. W. A. Dick.

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Discussion on "Current Population Problems with particular reference to the U.N. World Population Conference". Opening Speakers: Mr. B. Benjamin, Prof. E. Grebenik, Dr. W. P. D. Logan, Prof. Brinley Thomas, Mr. J. Hajnal and Dr. J. A. Fraser Roberts.

EUGENICS SOCIETY (at the Rooms of the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. Peter R. Cox: "Some Demographic Developments in Great Britain since the Royal Commission on Population".*

PHYSICAL SOCIETY, ACOUSTICS GROUP (in the Lecture Theatre of the Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Mr. R. A. Bull: "Modern Trends in Motion Picture Sound".

ROYAL MICROSCOPICAL SOCIETY (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. A. F. Hughes: "The Growth of the Neurone".

INSTITUTE OF PHYSICS, LONDON AND HOME COUNTIES BRANCH (at 47 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. A. M. Taylor: "Photoelectric Measurement of Polarized Light".

SOCIETY OF CHEMICAL INDUSTRY, CORROSION GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. C. H. Richards: "The Prevention of Corrosion in the Telecommunications Industry".

Thursday, December 16

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. M. F. Atiyah: "Recent Developments in Algebraic Geometry".

ROYAL AERONAUTICAL SOCIETY (at Church House, Great Smith Street, Westminster, London, S.W.1), at 5.15 p.m.—H.R.H. The Duke of Edinburgh—Tenth British Commonwealth and Empire Lecture.

INSTITUTE OF METALS, LONDON LOCAL SECTION (at 4 Grosvenor Gardens, London, S.W.1), at 6.30 p.m.—Dr. H. H. Scholefield: "Melting and Casting under Reduced Pressure".

INSTITUTION OF MECHANICAL ENGINEERS, INTERNAL COMBUSTION ENGINE GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Group Discussion—"It is Often Stated, Usually by 'Scientists', that Industry is Slow to Apply New Scientific Discoveries and Data, both in Regard to Materials and Design. Is this True of the Internal Combustion Engine World?"

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Prof. G. R. Clemo, F.R.S.: "Some Newer Aspects of the Organic Chemistry of Nitrogen" (Hugo Müller Lecture).

Thursday, December 16—Friday, December 17

INSTITUTE OF PHYSICS, STRESS ANALYSIS GROUP (in the Central Chemistry Lecture Theatre, The University, Reading), at 9.30 a.m. daily—Conference on "Stresses Due to Vibration".

Friday, December 17

BIOCHEMICAL SOCIETY (at Guy's Hospital Medical School, St. Thomas Street, London, S.E.1), at 2 p.m.—Scientific Papers.

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. C. S. Durst: "The Accuracy of Dead Reckoning in Air Navigation".

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Dr. F. P. Bowden, F.R.S.: "Recent Studies of Metallic Friction" (Thomas Hawksley Lecture).

ASLIB (at the Royal Society of Arts, 8 John Adam Street, Strand, London, W.C.2), at 6 p.m.—Mr. B. C. Vickery and Dr. G. Malcolm Dyson: "Advances in Classification".

INSTITUTE OF PHYSICS, NON-DESTRUCTIVE TESTING GROUP (at 47 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. H. F. Priestley: "X-Ray Fluorescence Analysis".

Saturday, December 18

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. T. L. Bartlett: "The Black-Headed Gull".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (graduate, with teaching experience) IN PHYSICAL GEOGRAPHY, at Gadjah Mada University, Jogjakarta, Indonesia—The Director, Personnel Department, British Council, 65 Davies Street, London, W.1, quoting "Indonesia" (December 17).

LECTURER IN PHYSICS—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (December 18).

LECTURER (with a degree in agriculture and some postgraduate experience) IN AGRICULTURE AND DIRECTOR OF THE COLLEGE FARM at Nafferton—The Registrar, King's College, Newcastle-upon-Tyne (December 18).

ASSISTANT LECTURER or LECTURER (well qualified in metallurgy, physics or physical chemistry) IN METALLURGY—The Registrar, The University, Leeds 2 (December 20).

LECTURER (graduate, with experience in industrial engineering and research) IN MECHANICAL ENGINEERING—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (December 20).

LECTURER IN BACTERIOLOGY at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (December 20).

LECTURER (with a recognized degree or diploma in agriculture) IN AGRICULTURE—The Clerk to the Governors, Essex Institute of Agriculture, Writtle, Chelmsford (December 20).

ASSISTANT (graduate in chemistry or biochemistry) IN BIOCHEMISTRY, at the Biochemical Laboratory of the Institute of Orthopaedics, Brockley Hill, Stanmore, for research work—The Dean, Institute of Orthopaedics, 234 Great Portland Street, London, W.1 (December 31).

DIRECTOR (with high scientific attainments, preferably in fields related to soils or crops, combined with administrative experience involved in the organization and running of a research institute or university department) OF THE EAST AFRICAN AGRICULTURE AND FORESTRY RESEARCH ORGANIZATION, Muguga, near Nairobi, Kenya—The Director of Recruitment (Her Majesty's Overseas Civil Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD 195/151/02 (December 31).

LAND DEVELOPMENT OFFICERS (with a degree or diploma in agriculture, and preferably with several years farming experience) IN the Department of Native Agriculture, Southern Rhodesia—The Secretary, Southern Rhodesia Government, Rhodesia House, 429 Strand, London, W.C.2 (December 31).

Research Assistant (graduate in natural science or in agricultural science, and a thorough grounding in entomology, plant pathology, systematic botany, and organic and inorganic chemistry) in the Department of Agriculture; and an Instructor in Agriculture (preferably with teaching experience and a degree or diploma in tropical agriculture) in the Education Department, to teach general tropical agriculture, both theoretical and practical, in close association with the Department of Agriculture—Public Service Commissioner, Western Samoan Public Service, Apia, Western Samoa (December 31).

Director of the Tea Research Institute of Ceylon—The Chairman, Tea Research Institute of Ceylon, St. Coombs, Talawakelle, Ceylon (January 1)

Lecturer in Bacteriology—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (January 8).

Lecturer/Senior Lecturer in Palaeontology, at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 8).

Chair of Electrical Engineering, and Chair of Civil Engineering—The Registrar, The University, Sheffield 10 (January 15)

Drummond Fellowship for Research in Nutrition—The Hon Secretary, Drummond Trust, University College, Gower Street, London, W C.1 (January 15).

Senior Technical Officer or Principal Technical Officer (with a degree in science or equivalent qualifications, and with experience in the collection of samples and the complete analysis of coal), in the Coal Research Section, Commonwealth Scientific and Industrial Research Organization, North Ryde, New South Wales, Australia, to supervise the collection, preparation, testing and chemical analyses of coal samples, in connexion with the Sections survey of the physical and chemical properties of Australian coals—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2, quoting 480/152 (January 15).

Chair of Mining Engineering at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, January 31)

Agricultural Engineer (with at least a first-class degree in agricultural engineering, and practical experience in farming methods), to be responsible for the development of the agricultural and engineering aspects of tillage and all phases of tobacco production, and the modification of existing equipment and machinery—The Director, Tobacco Research Board of Southern Rhodesia, P.O. Box 1909, Salisbury, Southern Rhodesia (February 15).

Aerodynamicists, Mechanical and Electrical Engineers, Physicists and Physical Chemists (with an appropriate first- or second-class honours degree or equivalent qualifications) at the Ministry of Supply National Gas Turbine Establishment, near Farnborough, Hants—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.780/54A.

Chemist-Assayer (with an honours or special degree in chemistry, and at least two years postgraduate experience in silicate analysis and assaying) in the Geological Survey Department, Gold Coast Government, to assay ore of all kinds and carry out silicate analysis of rocks and minerals, and to participate in research in the interrelation of Gold Coast rocks and in geochemistry—The Adviser on Recruitment, Gold Coast Office, Melbourne House, Aldwych, London, W.C.2.

Demonstrator (with an honours degree in physics) in Physics, at the Royal Military College of Science, Shrivenham—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.840/54A.

Head of the Department of Biology, Technical College, Bradford—The Director of Education, Town Hall, Bradford.

Laboratory Assistant (male) in the Human Physiology Division, Medical Research Council Laboratories Holly Hill, Hampstead, N.W.3—The Administrative Officer, National Institute for Medical Research. The Ridgeway, Mill Hill, London, N.W.7, quoting AD/49.

Physicist (with a good honours degree in physics) to assist in radium and X-ray problems, including rotational therapy, as well as radio-isotope work—The Director, Cancer Organization, Newcastle Regional Hospital Board, 3 Windsor Crescent, Newcastle-upon-Tyne 2.

Research Assistants (2) in the Iron Making Division, for work on problems concerning the preparation and smelting of iron ores—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "Iron Making".

Research Fellow, to assist Dr. P. A. Gorer with work on the serological study of transplantation immunity—The Dean, Guy's Hospital Medical School, London Bridge, London, S.E.1.

Senior Investigators and Research Assistants (with a degree in metallurgy, physics or engineering, or equivalent qualifications) in the Department of Industrial Metallurgy, for research on (*a*) the microstructure and properties of electro-deposits (under the direction of the Joseph Research Fellow); (*b*) the fatigue of light alloys; and (*c*) the production and properties of clad metals—The Acting Registrar, The University, Edgbaston, Birmingham 15.

Senior Lecturer or Lecturer (with teaching, research and/or industrial experience in electronics) in Physics—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3.

Senior Radiation Chemist (with ample experience in radiation chemistry and able to tackle any industrial problem in this field), to be responsible for a small group of chemists; a Physicist (with experience in nuclear physics), to design new irradiation sources and investigate irradiated products; and a Biologist (preferably with experience in radiation damage work), to collaborate with industrial concerns on the irradiation of foodstuffs and drugs—The Establishments Officer, United Kingdom Atomic Energy Authority, Research Group, Harwell, Didcot, Berkshire, quoting 2/103/167.

Senior Technician (familiar with, and experienced in, laboratory techniques), to assist in research on the linear accelerator—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, quoting "Senior Technician".

PERMUTIT

ION EXCHANGE MATERIALS

The use of Permutit Ion Exchange Materials in many roles distinct from water treatment, has resulted in the development of numerous new industrial processes giving improved results and lower running costs. Some materials now available are :—

Zeo-Karb Na. A sulphonated coal product containing both strong and weak acid groups.

Zeo-Karb 215. A nuclear sulphonated phenol resin containing also hydroxyl groups.

Zeo-Karb 225. A unifunctional cross linked sulphonated polystyrene resin in bead form of high capacity and exceptional chemical and physical stability.

Zeo-Karb 226. A unifunctional cross linked methacrylic acid resin in bead form containing only carboxyl groups as the ion active groups.

De-Acidite E. A high capacity anion exchange material of medium basicity.

De-Acidite FF. A unifunctional very highly basic anion exchange resin in bead form based on cross linked polystyrene and containing quaternary ammonium groups.

De-Acidite G. A unifunctional weakly basic anion exchange resin in bead form based on cross linked polystyrene and containing diethylamino groups.

De-Acidite H. A material similar to " De-Acidite G " but containing dimethylamino groups.

Bio-Deminrolit. A mixed cation and anion exchange resin for demineralisation in a single column.

Decalso F. A synthetic sodium aluminium silicate suitable for the separation and concentration of vitamins and hormones.

Decolorite. A resin of high porosity for removing colour from solutions.

Permaplex C-10. A highly selective cation exchange resin membrane containing SO_3H groups.

Permaplex A-10. A highly selective anion exchange resin membrane containing quaternary ammonium groups.

For full technical information please write to: THE PERMUTIT COMPANY LIMITED. Head Office and Laboratories: Dept. V.H.92, Permutit House, Gunnersbury Avenue, London, W.4. Telephone: CHIswick 6431

LECTURES AND COURSES

MIDDLESEX COUNTY COUNCIL EDUCATION COMMITTEE

ACTON TECHNICAL COLLEGE

High Street, Acton, W.3

Principal: R. W. MacAdam, B.Sc.(Hons.), Wh.Ex., M.I.Mech.E., F.R.S.A.

DEPARTMENT OF CHEMISTRY AND BIOLOGY

Head of Department: J. H. Skellon, T.D., M.Sc., Ph.D., F.R.I.C.

The following special courses will be held in the Department during the Spring Term, 1955. 1. Paper Chromatography and Ion Exchange in Analytical Chemistry. Six lectures by I. Smith, B.Sc., A.R.I.C., on Fridays at 7.30 p.m., commencing January 14, 1955. The course will include: Demonstrations on modern apparatus and technique in paper chromatography as applied in qualitative and quantitative work. Ion exchange. Chemistry of exchangers. Frontal, elution and displacement analysis. 2. Radio-isotopes and their Applications in Analytical, Inorganic and Organic Chemistry. Four lectures by staff of the Radiochemical Centre, on Fridays at 7.30 p.m., commencing February 25, 1955. The course will include: Technique of radioactive tracer methods and applications in analytical procedure. Dilution analysis. Activation analysis. Selected applications of radio-isotopes in inorganic and organic chemistry. Fee for each course, £1 1s. 3. Laboratory Course in Oils, Fats and Waxes. Fridays, commencing January 14, 1955, and throughout the Session, from 2 to 5.30 p.m. The course includes: Modern methods of analysis of oils, fats and waxes. Practical methods used for investigating composition. Standard analytical procedure. Fee, £2 2s.

Further particulars and forms of application may be obtained from the Principal.

C. E. GURR,
Secretary to the Education Committee.

UNIVERSITY OF LONDON

UNIVERSITY EXTENSION COURSES

(1) A course of 10 lectures on "Meteorology and Flight" by R. S. Scorer, M.A., Ph.D., of the Department of Meteorology, Imperial College Thursdays at 6.30 p.m., beginning January 20, 1955, at The Huxley Building, Imperial College, opposite Science Museum, Exhibition Road, South Kensington, S.W.7. If still available, tickets for the course can be obtained at the first lecture, but early application is advised. Fee 10s. Tickets from Deputy Director (N.Ex), University of London, Senate House, W.C.1. (2) A course of nine lectures on "Precision Measurement" by lecturers from the National Physical Laboratory, the Chemical Research Laboratory and the Royal Observatory, Mondays at 6.30 p.m., beginning January 24, 1955. At the Institute of Physics, 47 Belgrave Square, S.W.1. Admission by course ticket only. Fee 12s. 6d. Tickets can be obtained from the Deputy Secretary, Institute of Physics, 47 Belgrave Square, S.W.1.

MANCHESTER COLLEGE OF TECHNOLOGY AND UNIVERSITY OF MANCHESTER

A symposium on the Teaching of Analytical Chemistry. April 1 to 3, 1955. Programme: Friday, April 1, 6 to 9 p.m. (Schools); Saturday, April 2, 9.30 a.m. to 12.30 p.m. (Universities); Saturday, April 2, 2 to 5 p.m. (Technical Colleges); Sunday, April 3, 10 a.m. to 1 p.m. (Industrial and Professional Chemists). Entrance Fees: Inclusive of all sections, £2 2s. For any one section, £1.

Detailed programme from the Registrar, College of Technology, Manchester, 1.

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 to 64 inclusive, or a woman aged 18 to 59 inclusive, unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order, 1952.

MEDICAL RESEARCH COUNCIL WANT Physiological Technician at Pneumoconiosis Research Unit, Llandough Hospital, Penarth, Glam. Inter B.Sc. or equivalent qualification. Salary at point on scale £450 by £15 to £495 by £20 to £515 per annum.—Apply (two professional referees) to Director.

TOBACCO RESEARCH BOARD OF SOUTHERN RHODESIA

AGRICULTURAL ENGINEER

A fully qualified Agricultural Engineer is required by the Board at its Headquarters near Salisbury. Qualifications necessitate a minimum of a first-class degree in agricultural engineering, with practical experience in farming methods. The appointment will carry responsibility for the development of the agricultural and engineering aspects of tillage and all phases of tobacco production, as well as the modification of existing equipment and machinery. Commencing salary will range between £1,500 and £2,140 per annum, dependent upon the qualifications and experience of the successful applicant, who would be eligible for membership of the Board's Provident Fund and Medical Aid Scheme. Free passage to Southern Rhodesia would be provided.

Further particulars regarding the appointment will be supplied consequent on the receipt of applications, which should include the names of two referees and relevant personal details, addressed to the Director, Tobacco Research Board of Southern Rhodesia, P.O. Box 1909, Salisbury, Southern Rhodesia, prior to February 15, 1955.

TEA RESEARCH INSTITUTE OF CEYLON

DIRECTOR

Applications are invited from either Ceylonese citizens or Commonwealth subjects for the post of Director of the Institute. The Institute is situated on its own tea estate, 4,500 ft. above sea level, where the climate is temperate and healthy. The staff, which is expanding, comprises senior scientific officers 10, senior administrative officers 3, and junior officers, including some graduates, estate and administrative staff 50. The annual income derived from a cess on tea exports exceeds £125,000. Salary will depend on qualifications and proven ability. For an officer recruited from overseas it will be of the order of £2,500, plus allowances amounting to approximately £575 at present rates. Free quarters are provided and half all medical expenses are paid by the Institute. There is a provident fund to which the employee contributes 15 per cent and to which the Institute adds an equal amount. Overseas recruited staff are entitled to free passages to and from Ceylon for both officers and their families (not exceeding two children below the age of 12 years). Ceylonese citizens are not granted regular overseas leave facilities. The Director's agreement is for periods of three years, of which two years and six months are spent in Ceylon.

Applications or inquiries should be sent to the Chairman, Tea Research Institute of Ceylon, St. Coombs, Talawakelle, Ceylon, before January 1, 1955.

CHELSEA POLYTECHNIC

MANRESA ROAD, S.W.3

DEPARTMENT OF PHYSICS

Head of Department: Dr. W. H. George, M.Sc., Ph.D.(Lond.), F.Inst.P.

Applications are invited for the post of full-time Senior Lecturer (or Lecturer) in Physics. Candidates should possess teaching, research and/or industrial experience in electronics. Ample time and facilities for research will be provided. The successful candidate will be graded as Senior Lecturer or Lecturer, in accordance with qualifications and experience. The salary scales attaching to these grades are as follows: (a) Senior Lecturer: men, £1,065 by £25 to £1,215 per annum; women, £852 by £20 to £972 per annum, plus London allowance of £36 or £48, according to age. (b) Lecturer: men, £965 by £25 to £1,065 per annum; women £772 by £20 to £852 per annum, plus London allowance. Placing on the scale will be in accordance with previous service in a similar capacity.

Further particulars and form of application may be obtained by sending a stamped, addressed foolscap envelope to the Clerk to the Governors. Applications should be submitted as soon as possible.

QUEEN MARY COLLEGE

Queen Mary College (University of London), Mile End Road, E.1, invites applications for a Lectureship in Physics, to start during this session if possible, but if not, in October, 1955. Present salary scale £600 by £50 to £900; £900 by £50 to £1,150 (subject to increases in accordance with recent announcements), with F.S.S.U. participation and family allowance of £50 for each child. Initial salary £750 to £950 on the new scale, according to qualifications and experience.

Application forms (obtainable from the Registrar) should be returned by December 18.

EAST AFRICA HIGH COMMISSION

EAST AFRICAN AGRICULTURE AND FORESTRY RESEARCH ORGANIZATION

The Secretary of State for the Colonies invites applications for appointment as Director of the East African Agriculture and Forestry Research Organization, consequent on the retirement of the present Director, Sir Bernard Keen, F.R.S. The Organization is a Scientific Service of the East Africa High Commission, with headquarters at Muguga near Nairobi, Kenya. The post calls for proved high scientific attainments, preferably in fields related to soils or crops, combined with administrative experience involved in the organization and running of a research institute or university department. Experience of tropical conditions would be an advantage, but is not an essential qualification. The Organization works in close co-operation with East African Departments of Agriculture and Forestry on all research matters and maintains contact with territorial research work through specialized committees. At present the Organization is engaged in research on the physical, chemical and microbiological problems of tropical soils; on the genetics, physiology and pathology of arable and plantation crops, and on grassland production and animal industry, the latter jointly with the East African Veterinary Research Organization. The post is substantively of Deputy Chief Scientific Officer status in the Colonial Research Service, but Chief Scientific Officer status would be accorded *ad personam* to a successful applicant with high qualifications. The salary currently payable to a Chief Scientific Officer is £2,500 per annum. In addition, a local cost of living allowance, at present £350 per annum, is payable. A Director's house is available, for which a rental charge of £150 per annum is levied. Income tax at East African rates. Superannuation according to the conditions of the Colonial Superannuation Scheme. Free passages for officer, wife and children under 13 years of age on appointment, leave and retirement.

Applications, quoting reference number BCD 195/151/02, should be addressed to The Director of Recruitment (Her Majesty's Oversea Civil Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, and should reach him not later than December 31, 1954. Further particulars may be obtained from the Director of Recruitment.

GOVERNMENT OF NORTHERN IRELAND

CIVIL SERVICE COMMISSION

Applications are invited for a permanent and pensionable post of Scientific Officer in the Department of Industrial and Forensic Science of the Ministry of Commerce. The salary scale for men is £470 by £30 to £680 by £35 to £855, and for women £470 by £25 to £545 by £30 to £750. Candidates should have a first- or second-class honours degree in an approved scientific subject or other approved equivalent qualification. Previous industrial experience will be an advantage.

Preference will be given to suitably qualified ex-Service candidates who served in the 1914-18 or 1939-45 wars, provided the Commissioners are satisfied that such candidates are, or within a reasonable time will be, able to discharge the duties of the post efficiently.

Application forms and further particulars may be obtained from the Secretary, Civil Service Commission, Stormont, Belfast, to whom they should be returned, duly completed, with copies of two recent testimonials, so as to reach him not later than January 10, 1955

H.M. OVERSEA CIVIL SERVICE

Applications are invited for the following post: Laboratory Assistant, Department of Agriculture, Kenya. To carry out investigational work on problems of agricultural chemistry related to coffee culture. Candidates must possess a general degree in science or agriculture, with main interest in chemistry, or an honours degree in chemistry. Salary in the scale of £440 to £672 for women, and £550 to £840 for men, according to experience. Temporary cost-of-living allowance (at present 35 per cent of basic salary) and housing allowance. Appointment either permanent and pensionable after a probationary period of two years, or on contract for a period of 40 to 48 months. Overseas leave and free passages. On contract terms, a gratuity of 13½ per cent of basic salary is payable on satisfactory completion of contract. Income tax at local rates. Duties and status of post are those of Scientific Assistant.

Apply in writing to the Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, giving briefly age, qualifications and experience. Mention the reference number BCD 63/7/09

THE UNIVERSITY GRADUATE AND INDUSTRY

IN 1948 Dr. P. Dunsheath, in his book "The Graduate in Industry", set out to explain the opportunities which a career in industry offers to the university graduate, and to discuss the bearing of university teaching on the fitness of university graduates for an industrial career. Since then, relations between the universities and industry in Britain have grown steadily closer ; five conferences on the subject have been arranged by the Federation of British Industries, four of them dealing solely with such problems, and the Congress of the Universities of the Commonwealth last year also discussed the matter. The relationship of the universities to industry has also been considered by the Advisory Council on Scientific Policy, and by two of the productivity teams which the Anglo-American Productivity Council sent to the United States.

Nevertheless, in 1952 the Advisory Council on Scientific Policy could still refer, in a report on the man-power situation in regard to scientists and technologists in Britain, to the lack of knowledge, both among parents and teachers, of industry and the careers it could offer. Quite apart from the prejudices against an industrial career, on which trenchant comment has been made in the House of Lords and elsewhere, it is clear from similar comments in relation to the shortage of science teachers that neither ignorance nor prejudice has yet been dispelled. At the Federation of British Industries Conference at Ashorne Hill in October 1952, the responsibility of industry for explaining more fully, to students and their parents, as well as to the universities, the nature and opportunities of a career in industry was freely recognized.

Two handbooks which have recently been issued by the Federation of British Industries may be said to be the outcome of that Conference*. One of these, "A Career for the Graduate in Industry", is intended for the university student and is being distributed to universities and schools to encourage students to apply for industrial posts. The Federation estimates that 20 per cent of the staff posts in industry are open to graduate competition, and the booklet describes to the undergraduate very briefly what industry is and how it works, indicating something of the opportunities which it offers both to the science graduate and the arts graduate. The pamphlet is not intended as more than an introduction : the undergraduate seriously thinking of an industrial career must make his own further inquiries, but he is given more than a hint how to set about them.

What the handbook purports to do it does admirably. The undergraduate is given a clear idea of the qualities which industry will look for in its recruits from the university—whether they possess an arts degree or a science degree—the prospects industry can offer, and the contribution which the university mind can bring to industry. There is a glimpse of the vocational satisfaction which is to be found in an industrial career, and a note on salaries enables the prospective entrant to assess salary prospects in comparison with those open to him elsewhere. In producing this handbook, the Federation of British Industries has done a useful job with imagination and a sense of proportion, and it should meet a need to which attention has been frequently directed in recent years. The second handbook, "Industry and the Graduate", which is being distributed to all member firms of the Federation of British Industries and its affiliated trade associations, also meets a declared need on which strong comment has been made in connexion with the utilization of existing scientific and technical knowledge by industry. The pamphlet is written to bring home to industry, and particularly to firms which do not at present employ university graduates, even in science or technology, the importance of a high standard of education and personality in management, and the increasing extent to which industry to-day must recruit from the university if it is to obtain its proper share of the ablest young men and women in successive generations of school-leavers. That task is also very competently done, but the pamphlet also raises a number of fundamental questions, some of which are commonly ignored in discussions of this subject.

---

* Federation of British Industries. A Career for the Graduate in Industry. Pp. ii+24. Industry and the Graduate. Pp. ii+31. (London: Federation of British Industries, 1954.) 2s. each.

Discussing, for example, the educational changes affecting industry and, in particular, the disappearance of the financial barrier to university education, the pamphlet quotes figures to illustrate the serious extent to which industry's direct recruitment of the cream of school-leavers is now limited. Accepting the view, based on studies of the variation in intelligence over the community, that only about 9 per cent of boys of eighteen (having intelligence quotients of 120 or more) are generally suitable for senior posts of leadership—a standard about that required to obtain an honours degree—of 379,700 boys attaining the age of eighteen in 1912, some 34,173 would be suitable for leaders. For 1951, the corresponding figures are 305,700 and 27,513; but whereas in 1912, only 4,000 went to a university, 16,537 did so in 1951.

Thus while the number of those entering a university multiplied four times in the period, the number of school-leavers of the degree of intelligence which is desirable in leaders in any walk of life remaining for all types of employment, including industry, fell in the same period by almost two-thirds, from 30,173 to 10,976. If, moreover, we go further and consider the top 5 per cent in the intelligence-range, the situation is even worse. In 1912, out of 18,985 such school-leavers, some 14,985 were available for direct employment, whereas in 1951 the 15,285 school-leavers in that range were fewer than the university entry and none could be deemed available for direct industrial employment.

This situation is the direct result of the present otherwise admirable social doctrine in Britain that no barrier to higher education shall remain in the path of any young person who has the ability to profit by it. In spite, however, of the increasing tempo with which the most intelligent section of our youth is creamed off to the university, there will undoubtedly continue to be a few exceptions; but industry clearly can no longer rely on recruiting, from those left in the pool at the school-leaving age, boys and girls who possess the intelligence and the character desirable for leadership. To do so, the pamphlet suggests, is to risk disaster.

It may well be for consideration whether it is in the national interest to encourage all the more intelligent boys and girls to enter the universities, irrespective of whether they really desire a university education or are qualified, not so much intellectually as in other ways, to profit by a university education. It is obvious that the universities themselves are facing fresh problems from the change in the social structure represented among their students, quite apart from those arising out of the increase in the number of students. The ability to profit by a university education does not depend solely on intellectual ability, though without a certain level of intelligence a student clearly will be wasting his time at a university.

There is a problem here which merits further examination and on which the studies now being pursued by the University Grants Committee and also by Political and Economic Planning may in due course throw some light. It is, moreover, in this context that we should consider the possible exception to the selection process noted in this handbook. The incidence of the means test for the award of grants, coupled with income tax at its present rate, makes it impossible for the man with £1,500 a year or more to send more than one child to a university without great sacrifice in his standard of living. Even to send the first child involves considerable difficulties; and the pamphlet rightly suggests that the university stream is losing some good material. It should be noted, moreover, that the material that is being lost for such reasons is of a quality which, coming from homes where a tradition of culture and reading and good conversation is probable, might help to balance a deficiency which the University Grants Committee has already noted as causing difficulty in the universities. It is perhaps doubtful whether, as Dr. Eric Ashby has suggested, the universities have fully accepted the new responsibilities which these social changes entail. Even, however, when the universities have satisfied themselves as to the best methods of meeting these responsibilities and made the appropriate provision, there are other implications both for the nation in general and for industry in particular.

It cannot be accepted without further question that it is in the interest of the nation that so many students should go to a university at the public expense, not because they want to be scholars or professional men, or indeed to receive higher education at all, but purely because they are among the top 9 per cent of the nation's intelligence. There is still something to be said for a sense of vocation, and it is at least arguable that public money is spent to the best advantage in helping young people to qualify themselves for an occupation which they really desire to pursue. It does not even follow that all the nation's top intelligence will fructify best through university training, and it is still true that what is easily come by is apt to be correspondingly lightly esteemed.

That is one side. There is yet another, and two points made in the Federation of British Industries pamphlet bear closely on it. First, it will be noted that even in discussing the opportunities open to the graduate in science or technology, stress is laid upon the value of wider culture and informed opinion, in addition to detailed technical knowledge of the manufacture and performance of products, among representatives of a firm, particularly in overseas markets. Such qualities are fully as desirable among graduates, either in arts or in science, who seek to enter industry on the non-specialist or administrative side. Second, in advising on the recruitment of graduates, the pamphlet deprecates laying too much stress on academic distinction. It should not be taken for granted that only the first-class honours graduate is useful to industry. For many positions a man with second-class honours may be even more desirable, and for many others the graduate with a pass degree may be entirely adequate. Often, it is pointed out, the man who has been active in sport, debating society or other non-academic activity possesses qualities which more than compensate for any shortcomings in formal academic qualifications.

Something more is thus involved than the question whether the selection process is being pushed so far that the nation is not getting full return for the public expenditure involved. If indeed university education still satisfies Macaulay's criteria and opens, invigorates and enriches the mind, the waste is unlikely to be serious. Even, however, from the point of view of an industrial career, something more is rightly to be expected of a university graduate than clarity of thought and intellectual curiosity. Originality of thought and intellectual honesty, receptivity to new ideas, the capacity to assess evidence dispassionately, a sense of values and especially human values, and the ability to take the advice of experts and then to reach a decision—all these qualities are of prime importance to industry, especially on the managerial side; and provided the raw material is there, they can be developed by a university education.

The proviso is important. It is the real reason for viewing with concern the possibility that the universities are still missing some good material, as already suggested. Such material is at least as likely to possess the further qualities of integrity, intellectual and moral courage, and it is the more likely to use to the full the opportunities which a university affords of developing the extra-academical qualities than those who are channelled to the university purely on intellectual grounds and with no particular urge or sense of vocation. Often, indeed, it is the excessive importance attached to academic distinction by home influences, coupled with the denial of real opportunities for home and vacation study, rather than the indifference of the student, that is responsible for failure to profit to the full by the opportunities of a university life.

Increased university awards or maintenance grants are not in themselves the answer to this problem. If university standards are to be maintained, there must at least be example as well as precept, and that is one reason for giving very careful consideration to Mr. J. F. Wolfenden's argument that the universities would be doing a greater service to the community at large if they admitted to some of their places the young people who would be the leaders in other walks of life in addition to the learned professions, in place of some who are admitted to-day. The casualties might be no higher, and even those who failed would carry away something of value and might well have enriched university life. Otherwise there is more than a probability that the process of creaming off high intelligence to the university will involve also a levelling down, and that the equality of man will be realized at a low level rather than a high level.

Now Whitehead, in considering particularly the function of the university in preparation for a career in business or industry, has stressed also that here, too, that function is to promote the imaginative acquisition of knowledge, and he points out that the learned and imaginative life is a way of living. The combination of imagination and learning requires some leisure, freedom from restraint, freedom from harassing worry, some variety of experiences, and the stimulation of other minds diverse in opinion and diverse in equipment. Such conditions are not to be secured by purely financial means: there is also involved an attitude of mind, an outlook, an awareness of opportunities and a sense of proportion that it is difficult for the student to acquire if he comes from a home or a section of society where the purpose and functions of a university are not understood, or the whole climate of opinion has no conception of culture or the wealth and richness of human experience.

Dr. Eric James and Lord Montgomery may well be right in their emphasis on the importance of closer attention to the requirements of the really gifted student, who is destined to fill the highest posts when he reaches maturity. It may be essential to select early and to train such students specially; but on the argument itself they are a small class, and if they must be taught in small classes, industry will still in the main be concerned with recruiting its appropriate share of the top 9 per cent of the intelligence range. The problem remains of ensuring that that intelligence is so educated and trained, either before it enters industry or within industry itself, as to encourage not simply intellectual ability but also personality. It is the all-rounder with initiative and character, and not just professional training, technical knowledge, or academic distinction that industry most needs to-day. The Federation of British Industries has challenged its members to seek the talent they need in the quarters where it is increasingly most likely to be found. The pamphlet on "Industry and the Graduate", however, is an even more searching challenge to clear and constructive thought as to exactly where our present system of university awards is taking us, and whether some fundamental changes in the general attitude and thought about universities may be required. It may be that the present process of channelling so high a proportion of the nation's intelligence into the universities at the public expense needs reconsideration to ensure that we obtain the full benefit of such expenditure, and that there shall be no disastrous levelling down not merely in standards but also in talent, in enterprise and in vision.

RATS, MICE AND MEN

Control of Rats and Mice

Edited by Dennis Chitty and H. N. Southern. Vol. 1: Rats. Pp. xxxii+306+4 plates. Vol. 2: Rats. Pp. xvi+307–532+4 plates. Vol. 3: House Mice. Pp. xiv+226+8 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1954.) 105*s*. the set.

It has taken a Second World War to provoke a systematic study of those familiar commensals, the common rat and the house mouse. Now, they are being extensively investigated, both as pests and as animals in their own right; but before 1940 most of what passed for knowledge of rat or mouse biology consisted of myth or moral tale. Control, mostly ineffective, depended on alluringly advertised proprietary baits or contraptions, devised without any basis of critical research. The researches described in the three well-produced volumes under notice were carried out by members of the Oxford University Bureau of Animal Population, from the outbreak of war in 1939 to July 1947. Publication was not allowed during war-time and has been made possible now only by a private donation—a curious reflexion on the arrangements available for the dissemination of valuable knowledge. Much unpublished matter remains, and this is deposited at the Bureau.

Despite the delay, this is an important contribution to our knowledge of the biology of *Rattus* and *Mus*, and to the methodology of controlling their onslaughts on our food and our health. The first two volumes deal with work on rats, principally the common brown rat, *Rattus norvegicus* Berkenhout, but with some material on *Rattus rattus* L. The topics include the nature of the poisons used against rats; the biology of rats in relation to control methods; special observations on feeding behaviour; and some operational studies, including an account of experiments on rat control in Palestine and the Sudan. Each section reviews other relevant findings, notably from American work which, too, was stimulated by war; each has a bibliography. Some of the investigations described are inconclusive, and there are many loose ends; but bringing together such a body of work—an unusual enterprise, and one which might be copied elsewhere on a smaller scale—enables the many biologists and others interested in applied research and its organization to see what is involved in the investigation of three related pest species. On this general point, the introduction by the director of the Bureau, Charles Elton, is particularly worth study.

The procedures recommended for routine control by men with little training are necessarily highly simplified. D. Chitty and others show how laborious was the research which lies behind now familiar techniques such as prebaiting and change of bait and poison, and the actual selection of the poison and its concentration. About one thousand field tests, each usually lasting several weeks, were carried out, and some hundred tests were made on rats in cages. The results are, however, of interest to others besides the rat-catcher, the warehouse-keeper or the medical officer. These volumes contain original data on the closely observed behaviour of feral rats and mice—data of a kind which could not have been obtained from experiments on laboratory varieties. In its present form this information is adequately related neither to current ethological field studies nor to the psychology of white rats, and it presents a notable challenge to the student of mammalian behaviour. There is very full information on what the authors call 'new object reaction' in rats—an (innate ?) avoidance behaviour or 'neophobia' which clearly has much to do with the success of these animals. There is also information on poison 'shyness' or the refusal of a food which has caused illness—a phenomenon which should stimulate further study of the abilities of rats to select an advantageous diet.

On the ecological side, much has been learnt of rat population dynamics. Part of this work has been separately published; in these volumes the data on the growth and decline of rat numbers in different circumstances are scattered among several chapters, and are mainly related to assessing the effects of attempts at large-scale control. A. D. Middleton, for example, describes operational research on rat control on a group of farms—an encouraging instance of what can be done, at reasonable cost, with sound planning; and Elton and Laurie describe a sample census of rats and mice in corn-ricks in England, with results much less encouraging for those concerned with rural rat control.

The study of what actually happens to pest populations when control is attempted, in relation to the amount of damage they cause, is an essential basis for a rational system of control. The Bureau's findings make a useful starting-point for future operational research, but important generalizations on this topic are scattered through various chapters, or made only by implication: there is no point at which the threads of the argument on rat numbers are brought together in a unified statement.

There is greater unity in the third volume, on *Mus musculus* L., since the final writing was almost wholly the work of the editor, H. N. Southern. It was only with the Second World War that the house mouse was found to be a serious agricultural pest in Britain, but surveys from 1940 on showed it to be abundant on farms and highly destructive in ricks. In grain stores, of course, its activities can be devastating. Its behaviour is markedly different from that of the common rat: while the latter is conservative but 'suspicious', the mouse is mercurial and unpredictable. The Oxford work on this species has produced, for the first time, a sound basis for control by poisoning or trapping, and also a foundation for future studies of mouse biology.

The scientific worker on pest control must often, necessarily, be a jack-of-all-trades, though perhaps not necessarily with the proverbial corollary. Eight years of research by a team of such workers have, as would be expected, produced results of value to biologists working in a number of diverse fields, both 'pure' and applied. It is to be hoped that these volumes will be correspondingly widely used.

ANALYSIS BY CHROMATOGRAPHY AND ION EXCHANGE

Inorganic Chromatography

By Orsino C. Smith. Pp. x+134+5 plates. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1953.) 37s. 6d. net.

Chromatographic Methods of Inorganic Analysis

With Special Reference to Paper Chromatography. By Dr. F. H. Pollard and Dr. J. F. W. McOmie. Pp. viii+192+4 plates. (London: Butterworths Scientific Publications, 1953.) 30s. net.

Ion Exchanges in Analytical Chemistry

By Prof. Olof Samuelson. Pp. xviii+291. (New York: John Wiley and Sons, Inc.; Stockholm: Almqvist and Wiksell; London: Chapman and Hall, Ltd., 1953.) 52s. net.

It is natural enough that, when subjects assume such prominence in scientific research as ion exchange and chromatography, there will follow attempts to systematize the known facts by the publication of text-books. These three books should be considered against the background of the vast amount of unco-ordinated data to be found in the scientific journals. The only reasonable answer to the problem is for the text-book writer to confine himself to a portion of the subject, and to avoid so far as possible the tedious repetitions to which the reader is constantly subjected.

Mr. O. C. Smith, clearly, is overwhelmed with the complexity of his subject, as this sentence from p. 96 of his book, "Inorganic Chromatography", shows. "In this work many combinations were found to exist, and where several factors are present they are a multitude; for instance, whether the solution is acid, neutral or alkaline: type of solvent: type of adsorbent: kind of reagents and whether the developer is used before the sample or after: and ad infinitum". This has, no doubt, led him to overlook the almost complete unintelligibility of the last sentence of his paragraph on "Adsorption on Paper" (p. 5). In his discussion of "Apolar Adsorption" (p. 9) he does not distinguish between alumina and silica, which are normally regarded as instances of adsorption and partition, respectively.

Chapter 4 of his book suffers from the arrangement: the paragraphs are headed by authors' names instead of subjects, and constant reference to the index is necessary. In Chapter 5, although most paper chromatography has been done on filter paper *per se*, he begins by a description of the preparation of alumina-impregnated paper, which is a special case. Chapter 8, "Laboratory Procedures", is useful, but would have been better if more attention had been paid to the standardization of adsorbents. There is no attempt to describe alumina in chemical or physical terms, and, as variable amounts of water are added and the initial activity is not stated, it is possible that the activity is varying throughout an experiment. The packing of a column by a wet slurry process will not necessarily give the same results as a dry column. Magnesium silicate is difficult to define chromatographically, and as Mr. Smith himself states in relation to starch (p. 118), the results obtained with different batches of material are not always reproducible.

As regards the other two books, by Drs. F. H. Pollard and J. F. W. McOmie and by Prof. Olof Samuelson, respectively, the exposition is clear and the presentation logical. Pollard and McOmie give a review of inorganic chromatography which is as comprehensive as is possible on a subject that receives additional published researches daily. There are occasional slight obscurities; thus, the table of "Order of Adsorption" (p. 7) is too compressed and the word "column" in the text is ambiguous. The new qualitative analysis schemes are ingenious and sound; but before the 'classical' analysis is scrapped we should ask ourselves whether there is, in fact, a real advantage in the chromatographic method. It may well be that many laboratories will adopt some part of the scheme as a supplement to their normal methods, and in this case they will find the tables in the appendix of Pollard and McOmie of great help.

Ion-exchange materials form the subject-matter of Prof. Samuelson's book, and with these substances the analyst is completely in the hands of the manufacturer. It is a good sign for Anglo-American co-operation that the tables (pp. 261–264) list ion exchangers of British and European manufacture as well as those of American origin. It is clear that a selection of examples must be made if the book is not to reach encyclopædic size, and therefore specialists in subjects such as alkaloids and proteins may find the information too sparse; however, a reasonable bibliography points the way to further sources.

The book by Pollard and McOmie and that by Samuelson should find a place not only in every technical library but also at the practical analyst's desk.

E. Q. Laws

INTRODUCTION TO VECTOR AND TENSOR ANALYSIS

Vector and Tensor Analysis

By Prof. G. E. Hay. Pp. viii+193. (New York: Dover Publications, Inc., 1953.) 2.75 dollars, cloth; 1.50 dollars, paper.

The emphasis in this book is mostly on vector analysis, which is covered by five chapters, whereas but a single chapter is devoted to tensors. This, I think, is unfortunate for three reasons: published studies in vector analysis have already been considerable; tensor analysis is the generalized and therefore broader aspect of the vector–tensor approach; and there is a far greater need for an elementary-to-intermediate standard of book on tensors really suited to beginners working in the applied sciences. Moreover, in respect of tensors particularly, it is likely that there will be some measure of disappointment in engineering circles that the book is confined to the classical approach instead of supplementing the latter by the method initiated and developed by Gabriel Kron primarily for engineers. The point is worth making because there should be a greater measure of mutual recognition by pure and applied scientists of each other's needs and aspirations, coupled with effective joint action to obtain the best of both worlds.

Chapter 1 describes elementary vector operations up to the level of differentiation and integration with respect to a scalar variable and to linear vector differential equations. Chapter 2 gives applications of vector principles to solid analytic geometry and to differential geometry. Chapter 3 relates to the application of vectors to mechanics within the scope of motion of a particle and of a system of particles.

Chapters 4 and 5 deal with partial differentiation and with integration respectively and include studies of the del operator, line, surface and triple integrals, Green's and Stokes's theorems, and irrotational and solenoidal vectors. Chapter 6, on tensor analysis, dismisses the subject in a mere thirty-seven pages, but nevertheless it manages to present a concise account of the main essentials of the classical approach. For example, it includes co-ordinate transformation, covariant, contravariant and mixed tensors, the metric and conjugate tensors, lowering and raising indexes, the Christoffel symbols, and the curvature tensor, in addition to stating other topics of a kindred nature.

There are 195 problems (without answers), and although the book is said to be for students of engineering and mathematical physics, one can scarcely imagine that many of them will find much satisfaction from solving the problems except as exercises in pure mathematics. The type-setting and printing are excellent, but the work bears some evidence of hasty proof-reading. Considered as a condensed text in the classical manner, the book can well be recommended; and while it may help the embryo mathematical physicist, I much doubt that it will do the same for the young engineer.

FOOD FROM FRESH WATERS

Fertilizers in Fishponds

(Colonial Office, Fishery Publication No. 5, 1954.) By C. H. Mortimer. With additional material and a foreword by C. F. Hickling. Pp. iv+56. (London: H.M.S.O., 1954.) 25*s*. net.

It is often remarked on the Continent of Europe that in Britain scarcely any freshwater fish are exploited for food. Indeed, many who went to Britain during and after the Second World War investigated the possibility of carp farming on the German model. But sea fish is so readily available everywhere in the British Isles and, if truth be told, so much more palatable than carp, tench and pike, that it seems unlikely that such an industry could be established, even if the summer climate should prove to be warm enough to allow farmed fish to attain an economic growth-rate.

Nevertheless, during the War we had to consider to what extent our own fresh waters could contribute to our food supply, and Dr. C. H. Mortimer prepared for the Freshwater Biological Association a bibliography of publications on the use of manures to increase the productivity of fish ponds. In the event, we never had to exploit our fresh waters, so this paper did not attract the attention it deserved. Soon after his appointment as fishery adviser to the Colonial Office, Dr. C. F. Hickling appreciated the contribution freshwater fish could make towards remedying the serious protein deficiency that exists in so many tropical and sub-tropical countries and, by example and precept, has aroused an interest in fish farming throughout the British Colonies.

The literature on the subject is scattered and scanty, so no doubt Hickling found Mortimer's bibliography useful, with the happy result that they have collaborated to revise and extend the earlier publication and have produced a paper that every fish farmer and every freshwater biologist in the world should have. It is a very good bibliography, but it is a great deal more than that. The first forty pages are in fact a critical review of the literature and are most readable and informative. Then follow 108 pages which contain 351 references, and in every case where the title of the paper is not an adequate description of it there is an abstract. These abstracts vary in length from one line to rather more than four pages, and the long summaries of the most important publications are sometimes illustrated by graphs and tables. So the reader may find the information he needs in the abstract and can certainly discover whether the full paper is worth consulting—a very important matter in parts of the world remote from libraries. Lastly, there is an adequate index, making the publication handy to use.

H.M. Stationery Office ought surely to issue publications of this kind in something more durable than a paper cover. This book will be in constant use and will inevitably have to be given a permanent binding, so why should not the publishers do their job properly ?

F. T. K. PENTELOW

PROPERTIES OF MATTER

Properties of Matter

By H. N. V. Temperley. Pp. vii+323. (London: University Tutorial Press, Ltd., 1953.) 21*s*.

An outstanding feature of this excellent book by Mr. H. N. V. Temperley, which is intended for the degree student, is its emphasis on essentials. The usual descriptive matter is greatly condensed; indeed, only one experiment (the determination of g) is described in full, but this is done in great detail to illustrate the general principles of correcting for experimental error. The reader is left to supply for himself (guided by a mathematical appendix) the intermediate steps in the derivation of formulæ; and the author deals very thoroughly with the applications of classical mechanics to the behaviour of solids, liquids and gases.

The book is interesting to read for two reasons. The first is Mr. Temperley's graceful economy of words; an author who is as careful of his writing as of the subject-matter compels attention, besides setting a good example. The second is his outlook; for, as he says, although no especially striking advance has taken place in the twentieth century in the field of classical physics, there is no sign of any slowing-down of progress, quite the reverse, and the subject is still a very long way from being a 'closed' one. He gives many examples of the recent applications of classical physics—work at very high and very low pressures, ultrasonic absorption and the second coefficient of viscosity, the propagation of shock waves, and the behaviour of metals under plastic flow, to mention a few. The effect of this is to assure the student that classical physics is not only the grammar of the subject that he must master, but is also in its own right a living branch of the subject, with a future as well as a distinguished past.

Each chapter has a bibliography and examples for solution, and there is a collection of examination questions, chiefly from Part I of the Cambridge Natural Sciences Tripos and the London B.Sc. examinations. One's only criticism is of the publisher's modest statement that the book is suitable for students preparing for degrees in science; it would be fairer to describe it as invaluable for degree students preparing to be scientists.

G. R. NOAKES

THE UNIVERSITY OF HULL

By Prof. BRYNMOR JONES

Pro-Vice-Chancellor

ON May 13, 1954, H.M. the Queen granted a Charter constituting and founding a University within the City and County of Kingston upon Hull under the style and title of "The University of Hull", and so came into being the third new university to be established in England since the end of the Second World War—the others being Nottingham (1948) and Southampton (1952). In the years between the two Wars only one university, Reading (1926), was created, and it is necessary to look to the early years of the century for a precedent for the creation of so many universities within a space of a few years, when Bristol and the mid-northern universities were founded.

The English civic universities are largely a product of the twentieth century. Their growth, both in number and in the variety of their teaching and research departments, reflects the great expansion in the opportunities for higher education and for specialized studies in the past half-century; while their standing to-day among the universities of the Old and the New World is an incentive and an encouragement to those new foundations which have been added to their number in recent years. Although it is natural and desirable that each university should derive much of its ethos from its immediate surroundings, the newer institutions must, if they are to prosper and grow, strive to take their rightful place as national institutions.

Foundation and Development of the University College

Until the University College of North Staffordshire was established in 1949, the University College of Hull was the youngest of British university colleges. It was founded in 1927 with a gift of £250,000 from the late Right Hon. T. R. Ferens—but for his munificence and vision, and his concern to establish a centre of higher education in the city where he lived and prospered, there would not be to-day a university to enrich its life and to illume the plain of Holderness. But while Thomas Robinson Ferens is rightly acclaimed and honoured as the founder, the new venture would have been more tardy in its growth, and less attractive in its appeal, if it had not been fortunate in winning generous support from other quarters—in particular, from the City and County of Kingston upon Hull and from Mr. G. F. Grant, a prosperous leather merchant and a close friend of the founder. The City Council gave a sum of £150,000 for the first two buildings—one housed the arts department and the administration, the other the scientific laboratories, the library, the assembly hall, and the refectory. These were erected in 1927–28 on land given originally by Mr. Ferens to the City, and transferred by the City Council to the College. The choice of the site on Cottingham Road for the new College was a most fortunate one, for adjoining it was a large area of open land. This the Council of the College gradually acquired, so that when the opportunity for rapid expansion came at the end of the War, the College had some seventy acres of pasture-land available for new buildings and sports fields. In addition to the capital sum for buildings, the City Council agreed to make an annual grant, and so did the Education Authorities of the East Riding, Lindsey, and Grimsby, and the endowment of the College was enlarged by a bequest of about £100,000 by Mr. G. F. Grant. A number of special gifts and bequests were received both for general and particular purposes, and especially for scholarships. In this, too, the College was fortunate, for in those days grants and scholarships were less numerous than they are to-day—indeed, it was not uncommon for potential students to move from one university examination hall to another, in the hope that by their learning they could win enough in the way of scholarships to keep them at the university.

Some thirty students registered for the first session in 1928. Gradually their number grew, but only in one year before the War did the student-body exceed two hundred. Although on the outbreak of the Second World War there was not, as in the First, the same precipitate exodus of university students to join the Forces, the number of students in the College soon began to fall, and, as the City increasingly became a favourite target for enemy aeroplanes, the number of students fell back to a hundred. At one period plans were made for the organized migration of these to a less vulnerable part of the country: fortunately, the need for this never arose, and, despite the severity of the raids on the City, the College escaped serious damage.

At the end of the War, the College began to prepare for the difficult years ahead. It soon became clear that the pressure for places at the universities would be great, for in addition to the normal complement of students from the schools, there were many thousands of ex-Service men and women to be accommodated. To meet this great influx of students the Government asked all university institutions to admit as many students as possible. Although, in the absence of faculties of medicine and engineering, the College could not offer teaching in so wide a range of studies, it realized that it could offer ample opportunities for study in its two faculties of arts and pure science. Unlike most universities, it had land for new buildings and, of more immediate value, it had accommodation in existing buildings for many more students than were housed in the 'thirties. This was especially true of the humanities and of law, the requirements of which fortunately are so much simpler than those in science.

The potentialities of the College were quickly recognized by the University Grants Committee, some of the members of which visited the College in the spring of 1945, and in the summer of that year the College became eligible for the first time for Treasury grants both for revenue and capital purposes. In the following eight years the capital grants from the Treasury for new buildings, the purchase and adaptation of existing ones, the erection of temporary accommodation, and the provision of furniture and equipment for teaching and residential needs, amounted in total to well over a million pounds. In about the same period the number of full-time students at the College rose from the region of a hundred in 1944 to a peak of 917 in 1950–51—a

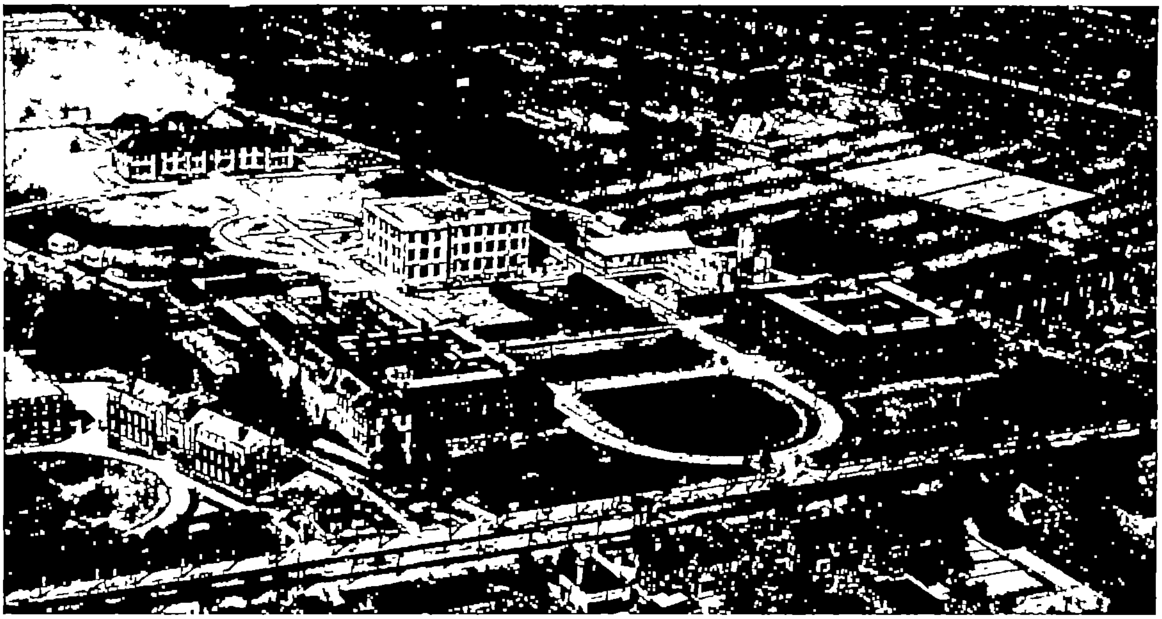

Fig. 1. Aerial view of the University of Hull. Centre block, new Chemistry Laboratories; right quadrangle, Science Buildings, left quadrangle, Arts and Administration; back, Students' Union. By kind permission of the *Hull Daily Mail*

total made up of 584 men and 333 women. In addition, many students were registered for part-time courses for diplomas and certificates, while some three thousand adult students each year attended evening classes and lecture courses both in Hull and in a large number of centres throughout the College area. An extensive scheme of tutorial classes and lectures for members of H.M. Forces was arranged by the Department of Adult Education in conjunction with Service Departments, and financed by a special grant from the War Office. To meet all these needs, the staff of the College was greatly enlarged. It now numbers about 135. Of these, twelve are engaged as tutors in adult education, and together they provide teaching in English, economics, history (including local history, and history of art), literature and drama, philosophy and psychology.

To meet pressing demands for accommodation, a number of temporary hutments were erected, and several of these were equipped as laboratories. While the furniture was of the best materials available at the time, the huts themselves were designed to serve for a limited number of years, for previous experience had shown that, in universities in particular, 'temporary' accommodation can all too often become permanent. Useful as these temporary laboratories have proved to be, they are no substitute for the well-built and well-equipped laboratories which teaching and research in modern science demand.

As licences were granted and building materials became available, work was started on permanent accommodation. The first was an addition to the original Arts building. This comprised in the main a number of lecture rooms for classes in the humanities; but it also allowed of an appreciable extension of the Department of Botany, which from the first days of the College had been housed on the top floor of the Arts building. The addition of new teaching and research laboratories, a lecture theatre, a herbarium, and some staff rooms has allowed for a welcome expansion of botanical studies. The Department has, too, a large experimental garden with a number of well-equipped glass-houses, stocked with a rich variety of plants, and especially of ferns.

A students' refectory seating four hundred, served by modern kitchens equipped with the latest mechanized apparatus, was built in 1950, and when this was finished, work was started on a Students' Union building. Together they form one of the most attractive centres for student life and activities in Britain. The Union has separate common rooms for men and women, and an excellently designed and furnished joint common room. In this building, too, is a Students' Council Room with the appropriate offices for Union officers.

The latest addition is the first section of a new science building to house the Department of Chemistry. This has a number of large and well-equipped teaching laboratories, rooms for research in the three main branches of the subject, three lecture theatres, and a large basement for stores. The completion of this building has made it possible to provide more accommodation for physics in the original science building by converting the laboratories used formerly by chemists for the use of physicists. There are two new laboratories for undergraduates, a number of research rooms and an additional lecture theatre. As a result, it was possible last summer to remove some of the temporary hutments. Along with the physical sciences, the biological sciences have also grown, and the Department of Zoology, like that of Botany, has had to be provided with more space. In addition to a new laboratory equipped specially for third-year students, the Department has now an up-to-date animal house and an aquarium. The erection of so many new buildings and the expansion of the work of the science departments have necessitated the building of a large new boiler house and of a modern workshop.

So far it has not been possible to house the Department of Geography in a permanent home of its own —a building for geography and geology is one of the needs of the new University. In the meantime, to cope with the greatly increased numbers in geography, a temporary laboratory was built. Of greater significance has been the creation of a chair of geography. The establishment of this new chair is a recognition of the intellectual value and practical importance of the subject, and of the work of the present head of the Department in building it up over a period of years.

When the University College was founded, the Council very wisely decided to establish only a limited number of departments, and to concentrate teaching and research to the major subjects. Thus, the emphasis was laid on philosophy rather than psychology, on geography rather than geology, and on classics, English, French and German as the main languages. But it had always been the intention that new subjects should be added, and new departments established. In the past few years many additions have been made. A Department of Social Studies was started in 1946, and two years later a lectureship in sociology was added. The range of teaching in the faculty of arts has been extended to include theology and music, and provision has been made for the teaching of Finnish and Swedish. Special appointments have been made by the Department of Economics and Commerce in public administration and in government. Geology has been added to the subjects in the faculty of science, and psychology, formerly attached to the Department of Philosophy, has been recently constituted into a separate department with a well-equipped laboratory of its own. Its courses are open to both arts and science students. The establishment of readerships in medieval history and in plant physiology have not only been of value to undergraduates with a special interest in these fields, but they have also helped to encourage research. There has been, too, a very substantial strengthening of the Department of Education, both in the number of its staff and in the provision of specialist teaching—including physical education, which has a modern gymnasium.

Along with the other university institutions, the College established an Institute of Education, with its own special library. It serves to promote the interests of education among those concerned for its practice and its administration in the College area, and it offers opportunities for further study, refreshment and investigation to teachers at all levels.

Research

Along with the expansion in the number of undergraduates, and the provision of more accommodation for teaching and specialist study, there have been welcome additions to the facilities for research in several departments. Considerable sums have been spent on new equipment, and the increase in the number of graduates engaged in research has become an important feature in the life of the College. A large number of research topics are being investigated by members of the staff in both faculties, and by research students working under their direction.

Library

The library, which has grown steadily over the years, was planned from the start as the centre of the academic life of the College, especially in the humanities. It has now some 120,000 volumes. In the first few years its growth was rapid; but, unfortunately, it has not kept pace with the increase in student numbers, or with the needs of specialist teaching and research. In part, this is due to the inevitable restrictions of the war years and to the greatly increased cost of both books and binding in the post-war years. Fortunately, monographs and

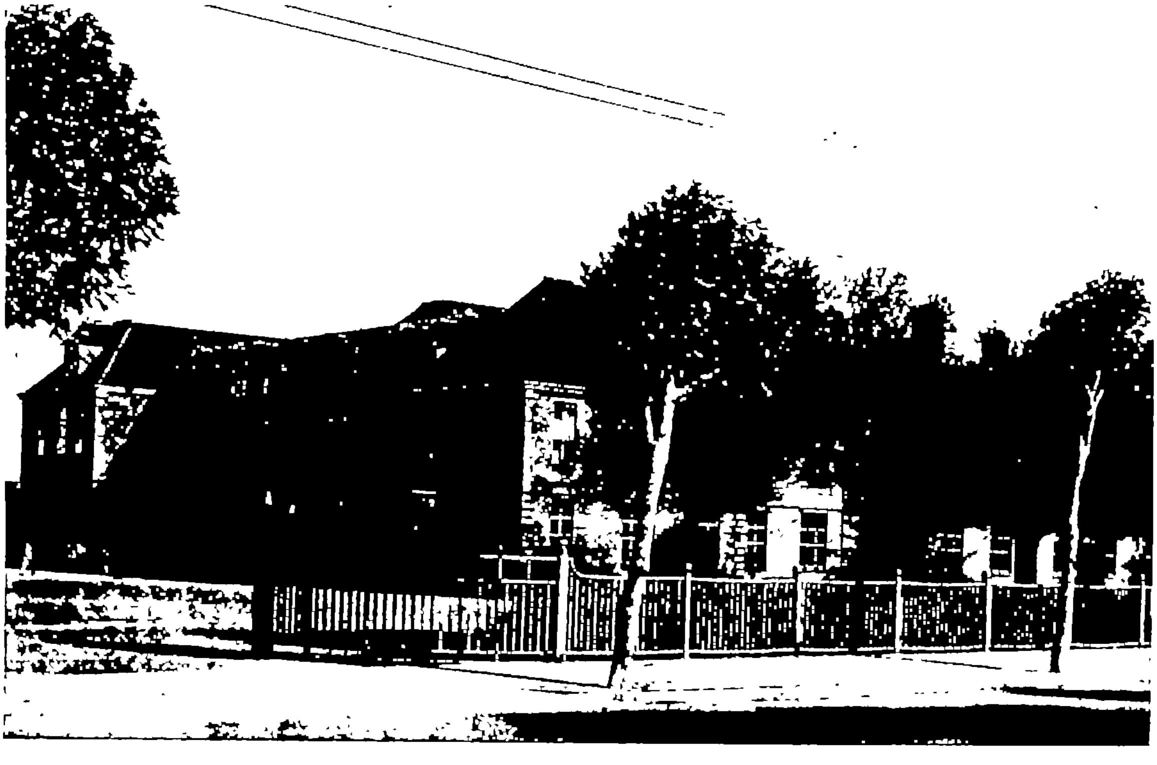

Fig. 2. Science Buildings

Fig. 3. Students' Union and Refectory

periodicals can be obtained on loan with reasonable ease from other university and industrial centres; but the building-up of the library on a large scale remains an urgent and pressing need in the years ahead.

The main part of the present library continues to be housed in accommodation on two floors of the science building intended ultimately for lecture rooms and staff rooms; but plans are well advanced for a new library building. The site for this is large enough to accommodate a building which will ultimately house a million books, and the plans make it possible for it to be built in sections. The stack in particular can be extended as the need arises. The main reading rooms and the rooms for administration will be built first, with such portions of the stack as are necessary for a term of years.

Halls of Residence

Two features have distinguished the College from most of the civic universities of Britain. In the first place, it did not evolve from a college of science, a technical college, a school of medicine, or a university extension college, but was founded as a new venture for the study of the humanities and pure science. No provision was made for medicine or for technology, although the incorporation of these was envisaged as a possibility at a later stage. In the second place, it has from its foundation required residence from all its students, with the exception of a small minority that lives at home. In this it resembles more the first Welsh colleges than the civic universities of England, where the majority of students live in lodgings or at home.

In the first year a hall for men was founded by Mr. F. Needler by adapting a large private house in the village of Cottingham—a distance of some two miles from the College itself. A hall for women was also established in Cottingham in Thwaite House, a large red-brick building standing in twenty-four acres of beautiful grounds. In the 'thirties two wings containing study-bedrooms were added to Needler Hall, to enable it to accommodate sixty-eight students. About the same time, Thwaite House was also enlarged by the addition of a number of separate study-bedrooms. In spite of these additions, both Halls continued to be regarded as temporary in character. The original plan of the College buildings envisaged the erection of halls of residence and athletic grounds adjoining the lecture rooms and laboratories; but, when the population of the College was growing rapidly in the late 'forties, it became clear that in the changed circumstances it would be better to keep the whole of the Cottingham Road site for academic developments. The advantages of this course have become apparent as new academic and social buildings have been erected. Although this has reduced the possibility of creating an academic, residential and athletic campus, it has assured ample space for further academic development, including, should the need arise, accommodation for one or more branches of technology or of medicine.

Once this decision had been reached, extensive additions were made to Thwaite Hall. These included more than a hundred study-bedrooms, a spacious reading room, and a finely proportioned dining hall.

The other hall for women—Cleminson Hall—comprises three large houses which have been adapted and modernized to constitute a hall for sixty-eight women. It has a light and exceptionally pleasant new dining hall, and its common rooms are unusual for the freshness of their decorations and furnishings.

Camp Hall is a temporary venture made up of a hutted camp, designed originally for families whose homes had been damaged in air raids. It has provided accommodation for three hundred men in separate study-bedrooms, each with its electrical heating. The hall has two dining rooms, and, in addition to the usual common rooms, it has a games room and a billiards room. This camp, acquired in 1946 and intended only for use as a hall for a limited number of years, has given yeoman service at a time when lodgings were hard to come by in a city severely damaged by air attacks. There is undoubtedly much that can be said against temporary buildings, both for academic and residential purposes; but in the immediate post-war period especially, they did enable the College to provide facilities for a large number of students who would otherwise have been deprived of the opportunity of a university education. The abolition of a large part of Camp Hall is now in sight, for work is well advanced on a permanent hall for a hundred and fifty men. This is to be known as Ferens Hall in honour of the founder of the College.

Athletics

The first section of an athletics centre, in close proximity to the Students' Union, was completed in 1950. In addition to the usual changing rooms for men and women, there is a squash rackets court. A first-class running track was constructed in 1952, and in the past two years some new records have been established in the course of the national athletic matches which have been held under the auspices of the Amateur Athletics Association.

Tennis courts have also been laid out in the grounds of the Halls at Cottingham.

The University

Such was the inheritance of the University when it was founded in May. The University College had been planned from the first as a university in the making: the Court of Governors, the Council, the Senate and the Boards of Faculties had from the foundation the customary powers. Indeed, it says much for the foresight of those who served on these various bodies in the early years that in the transition to full university status there was, in matters of government and control, so little need for change in established practice.

But in a number of other ways there was inevitably much new ground to be explored and many important decisions to be reached. This was especially true of the degrees to be awarded by the new university. For more than three years the planning of degree courses and syllabuses has been a major pre-occupation of the Senate and Faculty Boards. Before any firm decisions were made, a special Charter Committee set up by the Senate reviewed the degree structures of a number of universities, including those of the University of London, the examinations of which the students of the College have taken for more than twenty years. A number of criticisms and comments from schools and industry were assessed, and the experiments and changes proposed in other universities were borne in mind. The Committee found that it had to try to meet—or to balance—what seemed at first to be competing claims: the need of the country for more specialists in almost all branches of knowledge, and particularly in certain sciences, the dangers of over-specialization, and the plea both from industry and from schools that graduates should not be narrow specialists, but that they should at least be aware of the social problems which make their particular knowledge and skill so necessary in this age.

However well planned, only a part of all this can be covered by degree courses—for the rest, every university must rely on the inspiration of its teaching, on the enthusiasm and self-sacrifice which its staff brings to the discovery of new knowledge and to new ways of thought, and on its corporate life. But since the degree courses themselves must inevitably be the core of the intellectual training, their content and their relationship one to another are of first importance. While it is true that many undergraduates fail to broaden their mental outlook, it is equally true that the greatest single benefit a student can derive from a university education is the enlargement of his ability to go deeply into his chosen field. Such an experience should, and often does, provide a focus from which other and wider interests can readily be developed. Thus, while acknowledging the dangers of over-specialization, the Committee was at the same time alive to the value and importance of specialist training—for one of the main purposes of education is to impart an intimate sense of the value and power of ideas, of the structure of ideas, and of the beauty of ideas, thereby cultivating that most austere of all mental attributes, the sense of style.

Fig 4. Dining hall at Thwaite Hall

After careful consideration and discussion, the Senate and Council approved that there should be two kinds of degree—'special degrees' and 'joint degrees'. The special degrees are in one main subject, joint degrees in two main subjects. A 'general degree', with three subjects taken to final year, as in London and some other universities, was rejected, partly because experience has shown that few students reach a satisfactory standard in all three; but more particularly because the great majority of students fail to co-ordinate the knowledge so as to achieve some measure of synthesis. The special and joint degrees are based on the established principle that a student's general education is a matter for the schools. The radical solution of lengthening the course for a first degree to four years, with provision in the first of these courses designed to give a broad survey of existing knowledge and disciplines, was not adopted. While it is true that many students could with advantage spend a fourth year at a university, the extension of first-degree courses to four years is impracticable on financial grounds for the great majority.

The first-degree courses have therefore been planned to occupy three academic years. The whole of this time, however, will normally be devoted to post-intermediate work, since there is no 'intermediate' examination in the usual meaning of that term. The University needs, of course, to be satisfied that candidates have passed the General Certificate of Education in those subjects which will enable them to enter with profit on the degree courses of their choice. In most cases, though not in all, they will need to have a General Certificate of Education in the particular subjects which they propose to read for their degrees; but this does not necessarily mean that they must hold a certificate which will exempt them from the usual type of intermediate examination in three or four subjects. All students must, of course, be qualified to matriculate on terms similar to those accepted by most universities; but what is needed in addition has been determined solely in the interest of degree studies.

All candidates for the B.A. degree, except those offering mathematics or music for a special degree, must take one additional subject—either as a two-year 'subsidiary' or as a one-year 'ancillary'. Within this broad scheme there is a wide variety of choice, both in the combination of subjects for the joint degree, and in the subjects which may be taken at subsidiary and ancillary level. In the final examination, classified honours or a pass may be awarded in both degrees.

The regulations governing the degree of B.Sc. are similar, but with some important differences. Except in mathematics, all candidates for the special degree must take either a two-year subsidiary or two one-year ancillaries. The choice of these is in some instances closely defined, especially where the second subject becomes a tool for the fuller understanding of the main subject. Thus, all students wishing to specialize in physics are required to take mathematics as a subsidiary, and candidates offering philosophy as main subject must take a two-year course in psychology. Specialists in chemistry are required to take mathematics as one of the two ancillaries; but there is a free choice of the second. With the view of broadening the range of a student's reading, provision is made in each faculty for students to opt for any ancillary for which teaching is available in the other faculty. The stage at which examinations for the special degree are held varies with the subject. In some, the final examination will be held in two parts—Part 1 at the end of the second year and Part 2 at the end of the third year. In other subjects there will be one examination at the end of the third year.

Students for the degree of LL.B. take three examinations—a qualifying examination, and Parts 1 and 2. For the degree of B.Sc. (Econ.) the qualifying examination is at the end of six terms, and the final examination at the end of nine terms.

In addition there are many diploma and certificate courses, among them the course leading to the Graduate Certificate in Education taken by those graduates who choose teaching as a vocation.

The degrees of B.D. and B.Mus. rank as higher degrees, and courses leading to them may only be taken by candidates who have a first degree. The University has the power to grant the usual masters' degrees, and here special mention should, perhaps, be made of two such degrees—that of M.Sc. (Econ.) and M.Ed.—for which provision is not made in all universities. Provision has also been made for the degree of Ph.D. and the higher doctorates*.

The new University of Hull looks to the future with confidence. It aims to give to its students a broad and balanced approach to their studies, with provision for specialist training for those best fitted for it. While the larger universities can, in many cases, offer a wider range of study, with a greater variety of specialized courses, there are compensating advantages in a community of moderate size, where personal contacts both with students and with members of staff are more readily established. In the words of Prof. Bonamy Dobrée, the University aspires along with its sister universities to contribute to "the creation, generation by generation in a continuous flow, of a body of men and women who share a sense of civilized values, who feel responsible for developing them, who are united by their culture, and who by the simple pressure of their existence and outlook will form and be enlightened public opinion".

---

* Full syllabuses and notes on requirements are given in the University's 'Prospectus and Regulations".

CENTRE FOR RESEARCH ON MACROMOLECULES, STRASBOURG

THE Centre for Research on Macromolecules (C.R.M.), Strasbourg, is a foundation of the French National Centre for Scientific Research (C.N.R.S.). It is one of a series of specialized institutes each of which is devoted to a particular branch of research, and several of these are planned to be established in the course of the next few years.

This new institute is sited in Strasbourg because there was already in the faculty of sciences a university department for the study of macromolecules, financially supported by the National Centre. It is this nucleus that has been expanded and installed in a new building to become the new national centre for macromolecular studies.

The idea of the foundation, due to Prof. C. Sadron, the present director, is that it would facilitate the collaboration of physicists, chemists and biologists interested in macromolecular science. The physicist's part is the creation and the development of the necessary techniques for the investigation of the constitution of macromolecules by purely physical methods. In order to provide the materials for this work, teams of chemists and biologists are also necessary. Similarly, the physicists provide the finished tools for the use of the chemists and the biologists. In this way the highly specialized and difficult techniques and methods may all be applied so that correct interpretation of the results may be obtained in a very broad and difficult field. To provide for the carrying out of this broad plan, the following facilities and organization have been created.

The building is housed on four floors with a total area of about 35,000 sq. ft. In the basement on the ground floor are special rooms for precise physical measurements, administrative offices and general services. The first floor is devoted mostly to biology, some of the space having accommodation for spectroscopic instruments. The lecture room is also on the first floor and extends to the second floor as well. The second floor is concerned with chemistry and also houses the private apartments of the director.

The present staff consists of about sixty research workers, technicians, mechanics, secretaries and typists.

The physics section consists of about eleven people. It is directed by Prof. H. Benoit and is concerned with light scattering, Brownian diffusion, streaming birefringence, viscosity, fluorescence and dielectric constant as well as supersonic work. Infra-red and ultra-violet spectroscopic work are also the concern of the physics section.

There is also a separate section of X-ray studies with seven people directed by Dr. V. Luzzati. The topics here comprise the determination of molecular structures by conventional diffraction methods, the crystallinity of fibres and low-angle scattering by high polymer solutions. A Spinco ultracentrifuge and an electron microscope complete the equipment.

The biological section, directed by Dr. Vendrely, consists of ten people, and the two main topics are the structure of globular proteins and also the study of nucleic acids.

The chemical division is directed by Prof. J. Parrod, assisted by Dr. P. Rempp. It comprises two sections, the first being concerned with the synthesis of macromolecules of low molecular weight with a well-defined constitution, and the second with the study of polymerization reactions. Facilities for fractionation are also available in this section, and the particular concern of the polymerization section is elastomers.

The laboratory was formally opened on October 6. The ceremony was presided over by the Secretary of State for Scientific Research and Technical Progress in the presence of M. G. Dupouy, member of the Institut de France and director of the National Centre for Scientific Research, representatives of the Ministry of Education, and numerous personalities, French and foreign, belonging to the world of science and industry. An international colloquium was arranged on this occasion and some fifteen papers were given by eminent specialists on various aspects of the science of macromolecules. The colloquium was concerned not only with physics, biology and chemistry, but also with considerations of the industrial uses of high polymers, which come under the general care of the new Centre.

The Centre for Research on Macromolecules will therefore have the goal of contributing to the fundamental science of macromolecules, of furthering the progress of knowledge about certain essential properties of living matter, and of helping the development of the industrial production of high polymers. In this latter domain relations already exist between the Centre and various industrial establishments, the technologists of which are specializing in the various techniques needed for work on high polymers. Representatives from industries outside France will frequently discuss with the staff at the Centre problems concerned with the production of high polymers. The industry of the region will also be interested directly in the development of the Centre.

NEW INTERNATIONAL BAROMETER CONVENTIONS

By P. H. BIGG

National Physical Laboratory

THE purpose of this article is to bring to the notice of barometer users generally a new rationalized system of barometer conventions which has received strong support both in Great Britain and internationally, and will come into operation on January 1, 1955.

The development of the mercury barometer has been unfortunate in the number of scales which have come into use and in the variety of temperature and gravity values which have been associated with these scales. The use of three standard temperatures (0° C., 12° C. and 62° F.) with three variants of standard gravity (980·665 cm./s.^{2}, 980·62 cm./s.^{2}, and gravity at mean sea-level in lat. 45°), combined with the possibility of five scales (millibar, millimetre, inch, altitude in metres and altitude in feet), has been the cause of much misconception and error. The situation has been further complicated by the differing temperature coefficients of barometers with fiducial adjustment (for example, Fortin) and those without it (for example, Kew).

That much confusion and error were associated with the correlation and correction of readings on the various scales of these two types of barometer became increasingly evident to the National Physical Laboratory in the course of its barometric work; and hence, soon after the War, it initiated discussions with the Meteorological Office and the Ministry of Supply. At these discussions there was general agreement that simplification is most desirable. After consulting standards laboratories and meteorological organizations in the British Commonwealth and in the United States, and later the Comité International des Poids et Mesures, agreed proposals for the new system of conventions were submitted to the International Organization for Standardization (ISO) and the World Meteorological Organization (WMO). Committee ISO/TC12 of the International Organization for Standardization, which is concerned with quantities, units, symbols, conversion factors and conversion tables, at its meeting in October 1952 approved in principle the units associated with the new conventions and raised no objection to the adoption of the conventions as a whole. In 1953, the Executive of the World Meteorological Organization approved the proposals. The conventions have more recently been adopted by the British Standards Institution, and a British Standard* on the subject is in the course of publication.

The New Conventions

In the form adopted by the British Standards Institution, the rationalized conventions are as follows:

(1) *Pressure units.* Apart from the basic unit of pressure, namely, the dyne per square centimetre (symbol dyn/cm^2), the following pressure units only shall be recognized for barometric purposes. They are given in order of preference, the millibar being strongly recommended.

(i) The millibar, equal to 1,000 dyn/cm^2 (symbol mb).

(ii) The millimetre of mercury at 0° C and standard gravity 980·665 cm/s^2 (symbol mmHg).

(iii) The inch of mercury at 0° C and standard gravity 980·665 cm/s^2 (symbol inHg).

By 'mercury at 0° C' is meant a hypothetical fluid having an invariable density exactly 13·5951 g/cm^3. By 'inch' is meant a length of 25·4 millimetres exactly.

(2) *Standard instrumental conditions.*

(*a*) *Pressure scales.* Mercury barometers bearing scales representing the above units shall measure pressures directly in these units when the whole barometer is at 0° C and is subject to standard gravity 980·665 cm/s^2.

(*b*) *Altitude scales.* Mercury barometers bearing altitude scales shall correctly translate the applied pressure into the corresponding altitude (on the pressure/altitude relationship adopted) when the whole barometer is at 0° C and is subject to standard gravity 980·665 cm/s^2. (The definition of the various relationships between pressure and altitude in the atmosphere, and of the underlying assumptions, is not within the scope of the new barometer conventions, which are concerned with the conditions of use of barometers bearing scales complying with these relationships.)

The reforms which have been introduced arise mainly from the exclusive use of a single conventional value for standard gravity, together with a single reference temperature, in the definition of the millimetre and inch pressure units and in the standard instrumental conditions associated with all scales, including those of altitude.

---

* British Standard 2520. Barometer Conventions and Tables. (British Standards Institution, British Standards House, 2 Park Street, London, W.1.)

The need for relating barometric measurements to a definite gravity value has long been recognized. In the past, various values have been used. The recent general acceptance of the conventional value for standard gravity, 980·665 cm./s.^{2} (which is not now associated with lat. 45° and is therefore not liable to revision), and its adoption as the reference value for all barometric purposes, constitute notable steps forward. The similar use of a conventional value for the density of mercury at 0° C. is also a noteworthy advance, as it gives precision and permanence to the millimetre and inch pressure units, while not precluding allowance being made, in barometric measurements of extreme accuracy, for the actual density of the mercury at 0° C.

In the past, it has not been clear whether millimetre and inch scales on mercury barometers should be regarded as scales of pressure (as they are on aneroid barometers) or as scales of length set up to measure the length of the mercury column. The millibar scale has always been free from such doubt, the millibar being clearly a unit of pressure and not of length. It has now been decided to regard all three scales as pressure scales, giving readings in the standard pressure units when the barometer is under standard instrumental conditions.

Effect of the Changes

The adoption of the new conventions will greatly simplify the manufacture and standardization of mercury barometers, the correction of their readings to standard conditions, the final expression of pressures, and the conversion of either readings or pressures from one scale unit to another.

As aneroid barometers are also to be regarded as graduated in terms of the new pressure units, their readings will show the same inter-relationships as the scale readings on mercury barometers.

At a pressure of about 1,000 mb. the reading of a Fortin millibar barometer graduated on the new basis will be 2·0 mb. *greater* than one graduated on the old basis. This is almost entirely due to the change in the standard temperature of the mercury from 12° to 0° C., and the difference is proportional to pressure. Millimetre Fortin and Kew barometers will remain unaltered, because their scales have always been standardized at 0° C. At ordinary atmospheric pressures the reading of an inch Fortin barometer will be 0·01 *less* than before. This is due to the change in the length of the inch scale between 62° F. and 0° C. The difference is proportional to pressure. On account of the special temperature coefficients of Kew-type barometers, millibar and inch Kew barometers will not be affected in quite the same way as the corresponding Fortin barometers. Details will be found in B.S. 2520.

Implementation of the Changes

It is recommended that existing millibar and inch mercury barometers should be modified to comply with the new conventions as soon as is practicable, for example, when barometers are due for repair. As from January 1, 1955, the testing of barometers by the National Physical Laboratory will be based exclusively on the new conventions; new barometers will be required to satisfy the Laboratory tolerances. For the time being, barometers already in service will be admitted unaltered to the test provided that certain inscriptions required by the British Standard have been marked permanently upon them. To prevent misconception, a small label referring to the National Physical Laboratory test will be attached to any unaltered barometer which shows large index corrections as a result of the change in the basis of the pressure scale.

Save in exceptional circumstances, no accurate pressure measurements can be obtained with a mercury barometer unless due correction is made on account of temperature and gravity. The British tables hitherto used for this purpose have been derived for the most part from the International Meteorological Tables published in 1890 and not since revised. In relation to modern instruments and pressure units they have for many years been incomplete and, to some extent, inaccurate. The British Standard therefore incorporates comprehensive correction tables, applicable to all current types of mercury barometer, on the basis of the new units and conventions.

The advantages of the new system are permanent, and will far outweigh the inconveniences in first applying them. The conventions will be implemented in important government services and by the barometer manufacturers. It is hoped that scientific workers and others will henceforth express barometric pressures exclusively in terms of the international units and symbols, and, with the view of reducing to a minimum the period of change-over, that they will have their millibar and inch barometers brought into accord with the new conventions at the first opportunity.

I wish to acknowledge the responsibility of Mr. F. A. Gould, who was until lately in charge of the barometric work at the National Physical Laboratory, for the Laboratory's part in the development of the new conventions. This work was carried out as part of the research programme of the Laboratory, and the present paper is published by permission of the Director of the Laboratory.

OBITUARIES

Prof. R. E. D. Baker

Richard Eric Defoe Baker, professor of botany in the Imperial College of Tropical Agriculture, died in Trinidad on November 19, of heart failure after a short illness, in his forty-sixth year. His death is a great loss to botanical science in the tropics, and especially to the College which he served untiringly for more than twenty years.

Born in 1908, Baker was educated at Oundle and Trinity Hall, Cambridge, where he obtained a first class in Part II of the Natural Sciences Tripos; he also rowed for his College. After a year of postgraduate study at the Imperial College of Tropical Agriculture, of which he was awarded the associateship, in 1933 he was appointed lecturer in mycology in the College, and promoted to professor in 1945. Although his earlier interests were mainly in cryptogamic botany, in which he did outstanding work on witches' broom disease of cacao (*Marasmius perniciosus* Stahel), he was no narrow specialist, and in 1949 was appointed to the chair of the newly amalgamated Departments of Botany and Mycology. He was an enthusiastic student of the phanerogamic flora of Trinidad and since 1947 had been editor of the "Flora of Trinidad and Tobago", of which most of the parts dealing with the Dicotyledons have already been published or are in the press. He was in charge of the botanical sections of the banana and cocoa research schemes at the College, and in 1948 he went on an expedition to East Africa to collect wild and cultivated species of bananas for extension of the breeding stocks. In 1952 he led an expedition to Colombia for the purpose of collecting wild species of *Theobroma*. He was also largely responsible for the successful organization of River Estate, the College's field station for cacao research.

Baker (or 'Dick', as he was known to staff and students alike) had a charming personality, a great sense of humour, and an interest in many subjects apart from his profession. Although, perhaps, he sometimes found it difficult to suffer fools gladly, he freely offered his time and experience to those whom he did not consider to be fools, and in this his judgment was seldom, if ever, at fault. The news of his untimely death will be a great shock to the numerous past students of the Imperial College of Tropical Agriculture, now scattered over all parts of the British Commonwealth, who have been taught and inspired by him.

If he was not, in the ordinary sense, a religious man, he whole-heartedly put into practice that great precept, "Whatsoever thy hand findest to do, do it with all thy might". He has been buried in the College cemetery, next to the grave of his former professor, H. R. Briton-Jones, who died in 1936. He is survived by a widow and four daughters.

T. W. Kirkpatrick

Mr. H. G. Yates

By the very sudden and untimely death on September 15 of Mr. Henry George Yates, the marine turbine industry has suffered a serious loss. At the age of forty-six he had not reached the peak of his activities, and his abilities as a steam turbine designer in the marine industry were widely recognized and appreciated. He was widely read, interested in amateur dramatics, and had a happy family life, although his two children are only at the start of their scholastic careers.

The study of vibration was a great hobby of his. Anything from the vibration of a sewing machine at home to the most complex types of vibration occurring in geared turbine systems was strenuously investigated. He had outstanding patience in explaining the more abstruse points in designs. His eyesight had been defective from birth in one eye, but he developed amazing ability in dealing with complex mathematical formulæ in his head.

After a distinguished scholastic career, he graduated at Trinity College, Dublin, in 1930 with first-class moderatorships in mathematics and physics and was afterwards awarded the M.A. degree. He continued at the University as a lecturer in physics for two years before deciding that he would prefer to be an engineer. He served a student apprenticeship with the English Electric Co., Ltd., at its Willans Works, Rugby, and was employed after his apprenticeship in the Turbine Department of the Company. In 1940 a Research Department was set up, and Yates was put in charge of the work. He joined the Parsons and Marine Engineering Turbine Research and Development Association (Pametrada) very near the beginning, and was associated with the growth of the Association, particularly in the work of the Design Department, in which many designs were prepared for turbine machinery to be installed in important British and foreign ships, the total horse-power of the designs aggregating some seven million. During this time Pametrada acquired a number of foreign licences, which enabled Yates's work to influence building in countries such as Holland and Canada.

Yates was an associate member of the Institution of Mechanical Engineers, Fellow of the Institute of Physics, a member of the American Society of Mechanical Engineers, and at the time of his death was a member of council of the North-East Coast Institution of Engineers and Shipbuilders and chairman of the North-East Branch of the Institute of Physics. Apart from the technical committees of Pametrada on which he was a valued member, he was on the Admiralty Noise Reduction Panel NRP.2, AVGRA Sub-Committee *D*, the Admiralty Gearing Noise Advisory Panel, the Heat Transfer and Heat Exchange Committee of the Mechanical Engineering Research Organization and Committee *J* (Power Plant) of the British Electrical and Allied Industries Research Association.

The thing that struck most people meeting him for the first time was his great personal charm and very quiet way in explaining difficult points in design so that they became clear and easy to understand. He is greatly mourned by his colleagues at Pametrada, where he spent the last ten years of his life in charge of the Design Department.

Thomas W. F. Brown

Mr. E. Laurmann

The sudden death of Emil Laurmann on November 10 at the age of sixty-four came as a great shock to his friends and colleagues in the Royal Society Mond Laboratory, Cambridge. An Estonian by birth, he was trained as an engineer at Strelitz in Germany but was unable to complete the course owing to the outbreak of war in 1914; he worked for a time at Siemens in Leningrad, and then at the newly organized Polytechnic Institute, where he started his collaboration with Kapitza. In 1922 he followed Kapitza to Cambridge and for many years acted as his personal assistant, first in the magnetic department of the Cavendish Laboratory and later in the Mond Laboratory. His qualities of inventiveness, skill and patience in all sorts of techniques such as electrical engineering, fine mechanics, photography and the handling of delicate metal crystals, contributed largely to the successful outcome of Kapitza's investigations at very high magnetic fields. After Kapitza's return to the Soviet Union, Laurmann spent a year in Moscow helping to set up similar equipment at the Institute for Physical Problems and collaborated with Kapitza in studies of the Zeeman effect at very high fields.

During the years since the Second World War, Laurmann worked with me in various researches on superconductivity and the magnetic behaviour of metals at low temperatures, and I owe more than I can adequately express in words not only to his technical skill and ingenuity but also to his patience and good nature. Many others in the Mond Laboratory have also benefited from his advice and help, which he always gave willingly in a characteristically quiet and unassuming way; his presence in the Laboratory will be sadly missed. He is survived by his widow, a daughter and a son. D. Shoenberg

NEWS and VIEWS

Imperial College of Science and Technology: Appointment of Rector

Prof. R. P. Linstead, professor of organic chemistry in the Imperial College of Science and Technology, London, has been appointed rector of the College in succession to the late Sir Roderic Hill. Prof. Linstead had been director of the Chemical Research Laboratory (Department of Scientific and Industrial Research) before he went to his present post in the Imperial College in 1949 (see *Nature*, 163, 558; 1949).

Paris: New Scientific Attaché

Mr. A. C. Copisarow has been appointed scientific attaché to the British Embassy in Paris. Mr. Copisarow graduated in the honours school of geology of the University of Manchester in 1942, specializing in mineralogy and petrology. He served for four years in the Royal Navy, and was a member of the Ultra-Short-Wave Panel of the Scientific Advisory Council. Entering the Civil Service in 1947, Mr. Copisarow eventually became head of the Industrial Sub-Division in the Ministry of Defence. His published work includes a number of experimental papers on the colloidal chemistry of silica.

Sheep Biology Laboratory, Prospect, New South Wales: Dr. I. W. McDonald

Dr. I. W. McDonald has been appointed officer-in-charge of the Sheep Biology Laboratory, Prospect, New South Wales, of the Commonwealth Scientific and Industrial Research Organization, Australia, in succession to Prof. C. W. Emmens, professor of veterinary physiology in the University of Sydney, who has been acting as officer-in-charge since 1952 (see *Nature*, 170, 954 (1952), and also 171, 597 (1953)). Dr. McDonald is a former student of Hawkesbury Agricultural College and a graduate of the University of Sydney. After graduation he undertook research on the nutrition of sheep at the Animal Nutrition Laboratory of the Commonwealth Scientific and Industrial Research Organization and at the Institute of Medical and Veterinary Science, Adelaide, where he was appointed deputy director. In 1945 he went to the Universities of Cambridge and Sheffield, gaining a Ph.D. for studies in the metabolism of the sheep, with special reference to the digestion of protein, and since 1948 he has been a senior principal scientific officer at the Institute of Animal Physiology, Cambridge, where he has continued his researches on the processes of digestion in the sheep.

The Australian Museum, Sydney: Dr. J. W. Evans

Dr. J. W. Evans, deputy chief scientific officer of the Civil Service in Great Britain, has been appointed director of the Australian Museum, Sydney, in succession to Dr. A. B. Walkom. After graduating at Cambridge, Dr. Evans went to Australia in 1926 and joined the staff of the Council for Scientific and Industrial Research. He held various appointments in Australia and returned to London in 1944. He has had wide scientific and administrative experience. Though employed chiefly as an applied entomologist, his forty to fifty papers indicate wider interests in taxonomy, comparative morphology and ecology.

Scientific Work on Smokeless Fuels

In a Royal Institution Discourse on December 10, Sir Charles Ellis described the National Coal Board's research work into the production of high-class solid smokeless fuels. The problem, he said, is twofold: it is necessary to remove the volatile matter from coal in some way that pays for itself; and secondly, coal used must not be carbonization type, the long-term supply position of which is giving cause for considerable anxiety in Britain. The National Coal Board, he said, intends to develop a range of smokeless fuels that will be specialized to their individual purposes and will be premium fuels. In spite of the urgency of the situation, the Board believes that a long-term policy is necessary, and it is aiming at developing new processes that will represent a real technological advance.

One promising line of work starts with 'fines', or powdered coal. This is subjected to a fluidization process, in which a column of hot gas or steam is blown upwards through the fine coal in a heated vertical chamber; this results in chemical changes in the coal and the separation of the volatile substances and oils. The product of this process is difficult to make into briquettes, so a binder such as pitch is added; this involves a further process of carbonization. For this purpose the hot-sand carbonization process has proved to be of great importance. It gives rapid carbonization; also, it is a continuous process. A small plant working on a 50 lb. an hour scale has been completed and the possibility of the process established. A drawback of compressing the less suitable types of coal into briquettes is that a binder has to be used. Quite recently, Sir Charles said, it has been found at the National Coal Board's research establishment that these high volatile coals can be made to stick together without using any binder. This discovery may revolutionize our thinking on the whole subject of supplies to consumers.

Scientific Research and Industrial Productivity

In No. 7 (July 1954) of the "Occasional Bulletin" from Sondes Place Research Institute, Dorking, which resumes publication after two and a half years, the problem of research and productivity is discussed with reference to the more effective use by industry of applied science to improve its technological efficiency. It is recognized that labour productivity is not the only factor affecting the overall efficiency, nor necessarily the most important, and that productivity depends upon many factors other than economic, such as technical efficiency, the extent to which manual labour is lightened by the use of machines, enlightened and efficient management, good relations with trade unions, the existence of adequate incentives, taxation policy and the nature of the social system. Higher productive efficiency can never be achieved if any one of these factors is ignored; but, limiting itself to technological efficiency, the Bulletin argues that a more intensive application of scientific methods to industrial problems offers great potentialities for increased productive efficiency. Pointing out that 98 per cent of Britain's factories employ less than two hundred and fifty workers but that more than 50 per cent of the country's industrial workers are employed in such factories, the Bulletin comments that, if the survey recently conducted by the Manchester Joint Research Council is representative of conditions elsewhere, up to half of the population of Great Britain is employed in industries where the chances of greater productivity arising from technological advances are remote. For such small firms the independent research institute is particularly useful, and the

Sondes Research Institute has always endeavoured to supply the research tools and the trained staff which such firms lack. All rights in any discoveries made in a project are automatically assigned to the sponsor, so that the Institute may be regarded as the research department of the sponsor for the duration of the project. Experience at Sondes Place confirms the difficulty of liaison with industrialists who are unable to define their own problems in terms which the technical man can understand, and also the backwardness of small firms in appreciating the contribution science can make to improving productivity.

Technical Graduates in the British Armed Services

IN written answers to Parliamentary questions on November 22, the Minister of Defence, Mr. H. Macmillan, stated that about 940 uniformed personnel at present employed on instructional duties in the Fighting Services hold degrees in science, including mathematics and engineering, the average annual intake for this purpose into the Royal Navy and the Royal Air Force together during the past three years being about 165. In addition, some 120 civilian science or engineering graduates are employed on instructional duties with all three Services, with an average annual intake of about ten during the past three years. Some 2,860 civilian science and engineering graduates are employed on research and development by the Service and supply departments, the average annual intake during the past three years being about 185. Science graduates are not recruited into the Services specifically for research and development duties, but about 110 uniformed personnel holding degrees in science, including mathematics and engineering, are in addition employed on research and development for the Services.

J. A. Gilruth and his Influence on Commonwealth Livestock Industries

THIS year the Macrossan Memorial Lecture was given at the University of Queensland by Sir Ian Clunies-Ross, chairman of the Commonwealth Scientific and Industrial Research Organization, Australia, who chose as his subject "John Anderson Gilruth: the Influence of his Life and Work on the Development of the Livestock Industries of the Commonwealth". Gilruth combined a forceful personality with true administrative and scientific ability. After training as a veterinarian at Glasgow, he spent seventeen years in New Zealand, where he built up what was probably the best government veterinary service in the British Commonwealth. Sir Ian considers this service one of the chief reasons why New Zealand achieved such a high reputation for exports of lamb and dairy produce. In 1909 Gilruth was appointed the first professor of veterinary science in the University of Melbourne, where he established the first five-year veterinary course in the British Commonwealth, if not in the world. The last and equally fruitful phase of his career started in 1929, when he was appointed chief of the Division of Animal Health of the then newly formed Council for Scientific and Industrial Research, now the Commonwealth Scientific and Industrial Research Organization. His sound judgment and planning have been reflected in the output of important research by the Organization in nutrition and infectious diseases, much of it fundamental in nature. His strong personality and original mind were responsible for the initiation and successful pursuance of a number of investigations that have yielded far-reaching results. Sir Ian then reviewed the achievements of Australian scientific workers in these fields and closed by pointing to some major problems still confronting the further development of Australia's agricultural industry—problems that offer a fascinating challenge to the best scientists that the country can produce.

Indian Journal of Fisheries

THE first issue of a new journal, the *Indian Journal of Fisheries* (1, Nos. 1 and 2; May 1954; pp. 416+8 plates; Rs. 7.8 net), published by the Ministry of Food and Agriculture of the Government of India, New Delhi, has recently appeared, and the welcome that one would normally accord to a new periodical devoted to scientific research in India is all the warmer for one that deals with questions likely to increase food supplies. The journal deals with fisheries research in Indian and adjacent waters—freshwater, lacustrine and salt water—and there are papers on plankton, algae, molluscs, crustaceans and fish. In all cases attention is given to the practical aspect of ensuring a continuation and improvement of the fish supply, the spawning and growth of fish being carefully considered. A detailed description is given of the Central Marine Fisheries Station, Mandapam Camp, Southern India, and this account must arouse envy in the hearts of fishery research workers in Europe, for there are twenty-three scientific officers, twenty-two research assistants and fourteen fishery survey assistants, in addition to the normal administrative staff. There are also subsidiary research stations, notably in Calicut and Karwar, and an inland fisheries research station has been established in Calcutta. There are lists of the publications issued at Mandapam and Calcutta. The Government of India is to be heartily congratulated, since in this issue of the new journal practically no problem connected with the fisheries is overlooked or neglected.

Fisheries of Lake Chilka in Southern India

CHILKA LAKE, which is situated on the east coast of India near Puri in the State of Orissa, is really a lagoon, for it communicates with the open sea by a narrow channel fourteen miles long. In the rainy season the area is 450 square miles, shrinking to 350 square miles in dry weather. It is very shallow, varying in the dry season from 3 to 4 ft. in depth. The salinity varies from practically fresh water to a high salinity near the sea entrance. Consequently, there is a remarkable fauna, both of fish and invertebrates. The total number of species of fish known in the Lake is 138. Large quantities of carp fry drift down into the Lake during floods and are utilized for stocking freshwater tanks. The shallowness of the Lake makes fishing comparatively easy, and the bulk of the catches goes by rail to Calcutta. A full description of the methods of fishing is given in the paper by S. Jones and K. H. Sujansingani in the first volume of the new *Indian Journal of Fisheries* (see above). The chief food fish are mullets, clupeoids, catfishes, sciaenoids, perches and bekti, and the yield per acre (both fresh and dried fish) amounted in the years 1948, 1949 and 1950 to 34·48, 31·58 and 29·80 lb., respectively. Since the Lake is an uncultivated piece of water and more than a fourth of it is too shallow to support a good fishery, these totals must be considered satisfactory. The authors recommend the abolition of the present zemindari (landlord) system and the transfer of the fishing rights to the State.

Methods of preserving the future supply are carefully considered, and a minimum size limit for fishes of economic importance during certain seasons is recommended. The crab fishery of the Lake has also been dealt with by the same authors (*J. Bombay Nat. Hist. Soc.*, 1952), and great credit is due to them for these two valuable reports.

Scientific Observations on Heard Island in the Antarctic

The Southern Ocean—the ocean surrounding the Antarctic Continent—is divided into two main hydrological zones by the Antarctic Convergence, the line of demarcation at the surface of the ocean between the cold antarctic water and the warmer sub-antarctic water. The Ocean contains several isolated islands and groups of islands, including the following: South Georgia, South Sandwich Islands, Bouvetoya, Prince Edward Islands, Iles Crozet, Iles de Kerguelen, Heard Island, Macquarie Island, Campbell Island and Auckland Island. Differences in their altitudes, atmospheric circulation and ocean currents, combined with their positions relative to the Antarctic Convergence, have resulted in some of these islands being ice-covered and glaciated whereas others are clothed in grass and other non-arboreal vegetation. Heard Island (lat. 53° S., long. 73½° E.), which lies about nine hundred miles north of the western sector of Australian-Antarctic Territory, is a typical ice-capped antarctic island. The recent establishment of a research station by the Commonwealth of Australia on Heard Island makes it possible to provide the first comprehensive scientific information on the geography, geology, meteorology, flora and fauna of the Island. This report has been prepared by P. G. Law and T. Burstall and issued by the Antarctic Division, Department of External Affairs, 187 Collins Street, Melbourne (Interim Report No. 7; pp. 32+7 plates; 1953). It also contains accounts of recordings to extend studies in geomagnetism, seismology and knowledge of cosmic rays, as well as observations of the aurora australis.

University of Birmingham

The following have been appointed lecturers in the University of Birmingham: E. H. Wright (mechanical engineering), Dr. S. A. Barker (chemistry), Dr. K. F. Chackett (physics), C. B. Wright (physical metallurgy), Dr. J. D. Blainey (experimental pathology), J. B. W. Halley and K. R. Thornton (pathology), and Dr. N. S. Ross (Harry Payne lecturer in employer–employee relations). The following have been appointed to research fellowships: Dr. Jacques Vilain, Dr. P. D. Whitaker and E. A. Finlay (physics); Dr. O. Theander, Dr. A. Sykes, Dr. C. R. Patrick and M. Kapel (chemistry); Dr. E. L. Breese and Dr. F. W. Allard (genetics); J. R. Coope (geology); Dr. A. D. Hudson, Dr. Francine Gregoire and Dr. A. L. Woolf (pathology); Dr. P. B. Bradley (experimental psychiatry); and W. A. Coppel (pure mathematics). The following have resigned from the University: Dr. Hilde Behrend, research fellow in commerce, and J. S. Howell, research fellow in pathology. The National Coal Board has provided a sum of £1,600 for research in the Department of Mining of the University, and Unilever, Ltd., has made a grant to the Institute of Engineering Production of £200 a year for seven years towards expenses of the Institute. In the Department of Chemistry, 15,000 dollars has been provided by the Rockefeller Foundation for Prof. M. Stacey's research in biochemistry, the amount to be spent over three years, and the Geigy Company has sponsored a research fellowship in the field of organic chemistry for one year.

Announcements

Prof. R. E. Glover, professor of veterinary pathology in the University of Liverpool since 1949, and a past president of the Royal College of Veterinary Surgeons, has been appointed principal and dean of the Royal Veterinary College in succession to the late Prof. J. B. Buxton.

The Minister of Agriculture and Fisheries and the Secretary of State for Scotland have appointed Lord St. Aldwyn, joint parliamentary secretary to the Ministry of Agriculture and Fisheries, as chairman of the Myxomatosis Advisory Committee in succession to Lord Carrington. Dr. I. Thomas, deputy chief scientific officer to the Ministry of Agriculture and Fisheries, has been appointed a member of the Committee in succession to Dr. J. W. Evans (see p. 1130).

Lieut.-Colonel L. F. Urwick has been awarded the Wallace Clark International Management Award for 1955. This Award has been given annually since 1948 by the American Society of Mechanical Engineers, the American Management Association, the Society for the Advancement of Management and the Association of Consulting Management Engineers, and is presented by the Council for International Progress in Management (U.S.A.), which represents the American management movement internationally. Colonel Urwick is the first British national to receive the Award.

Under the will of the late Francis Amory, the American Academy of Arts and Sciences is offering a substantial prize for outstanding work on some aspect of the alleviation or cure of diseases affecting the human reproductive organs, in particular those of men. Nominations, supported by statements of qualifications with regard to work done since 1947, should be sent as soon as possible to the American Academy of Arts and Sciences, 28 Newbury Street, Boston 16, Massachusetts.

The Institution of Naval Architects is offering the following scholarships for training in a university institution: *I.N.A.–Elgar–Martell Scholarship*, for naval architecture, worth £275 a year, which is open to British subjects less than twenty-three years old who have been employed for at least two years upon shipbuilding (entries close January 14, 1955); *Denny Scholarships*, one in naval architecture and one in marine engineering, worth £175 a year for four years at the University of Glasgow, with apprenticeship of five years, which is open to British subjects less than nineteen years old (entries close May 31, 1955). Further information can be obtained from the Secretary, Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1.

A telegram has been received from Copenhagen announcing the discovery by Abell, at Palomar, of an asteroid on December 3. Its position was R.A. 7h. 08·1m., Dec. −21° 19′; daily motion: in R.A. −06m. 46s.; in Dec. −01·25°; mag. 17; appearance stellar.

Erratum. In the article on "Chemistry of some Natural Pigments" in *Nature* of November 27, p. 990, col. 2, eight lines from the bottom, for ". . . introduced into tetramethyl tetrazaporphin . . ." read ". . . introduced into octamethyl tetrazaporphin . . .".

ROCKEFELLER FOUNDATION GRANTS

GRANTS made by the Rockefeller Foundation during the third quarter of this year totalled 1,015,696 dollars. During the same period, the Foundation awarded thirty-nine fellowships to individuals from twenty countries. Among the grants to institutions are the following: £24,000 and 10,000 dollars (about 82,000 dollars in all) to the Royal Technical College, Glasgow, for post-graduate training and research in environmental control engineering, to be conducted with the several new towns in the Scottish Highlands in mind, which are now in varying stages of development; 50,000 dollars to the Department of Biochemistry of the Pasteur Institute, Paris, for the purchase of research equipment and other purposes; 45,000 dollars over five years to the Department of Chemistry, University of Edinburgh, for research on natural high polymers; 12,000,000 lire (about 22,000 dollars) over a period of three years to the Institute of Zoology, University of Pavia, for cytogenetic studies of mosquitoes; 30,000 dollars to the Marine Biological Association of the United Kingdom for use at its laboratory in Plymouth; 30,000 dollars to the Strangeways Research Laboratory, Cambridge, for the purchase of an electron microscope; 30,000 dollars over three years to the biophysical research unit at King's College, London; 30,000 dollars over three years to the Gordon Research Conferences of the American Association for the Advancement of Science, as a continuation of previous aid for financing the visits of selected foreign scientists to the United States to attend conferences on the chemistry of biologically significant molecules; 15,000 dollars over two years to the Royal Institution of Great Britain and its associated Davy Faraday Research Laboratory towards the expenses of research on the structure of proteins; 15,000 dollars over three years to the University of Birmingham for further support of the research in the chemistry of carbohydrates under the direction of Prof. M. Stacey.

Other grants made in the third quarter of this year include the following: 500 dollars to Dr. George Otto Gey, director of the Division for Cellular Pathology, Department of Surgery, Johns Hopkins University, Baltimore, to visit European laboratories conducting work in cell research and virology; 10,000 dollars to the Inter-American Society of Soils Scientists for meetings of the Society during the period ending March 31, 1956; 5,000 dollars to the University of Arizona, Tucson, for a conference on the problem of cloud physics research held in Tucson during August 1954; 3,500 dollars to McGill University, Montreal, for aid to the general organizing committee in preparation for the Tenth International Congress of Genetics to be held at McGill in 1958; 1,000 dollars to the University of Liège for research in carbohydrate chemistry, under the direction of Dr. Claude Liébecq, of the Institute of Higher Physical Education; 2,200 dollars to the University of Paris, for research in chemical genetics, under the direction of Prof. Boris Ephrussi; 6,000 dollars to the Institute of Anatomy, Karolinska Institute, Stockholm, as a further contribution towards the purchase of an electron microscope to be used for research under the direction of Dr. Fritiof S. Sjöstrand; 5,000 dollars to the Institute of Physiology, University of Geneva, for the purchase of equipment to be used by Prof. Jean Posternak; 7,500 dollars to the University of Glasgow for three small working conferences of European scientists interested in genetical problems, to be held during the five-year period beginning January 1, 1955; 7,200 dollars to the Department of Biological Chemistry, University of Aberdeen, for equipment to be used in general biochemical research; 2,000 dollars to the Department of Natural History, University of St. Andrews, for equipment for research in marine biology; 895 dollars to the Virus Research Institute, Lagos, for air-conditioning equipment; 5,500 dollars to the Department of Physiology, Medical College, Indore, for equipment to be used under the direction of Dr. J. C. Sachdev; 2,000 dollars to the Department of Microbiology, Institute of Public Health, Tokyo, for the application of tissue culture methods to the study of viruses; 2,000 dollars to Dr. Konoshin Onodera, of Kyoto University, to visit the United States for research in carbohydrate chemistry at Ohio State University, Columbus; 3,000 dollars to Prof. Juan Sanchez Salcedo, jun., professor of chemical hygiene and nutrition, Institute of Hygiene, and professor of biochemistry, School of Medicine, University of the Philippines, Quezon City, to observe new developments in biochemistry and nutrition in Europe and the United States; 5,000 dollars to the Department of Biochemistry, University of Minas Gerais, Belo Horizonte, for equipment to be used by Dr. James B. Sumner; 39,200 cruzeiros (about 1,000 dollars) to the University of Rio Grande do Sul, Pôrto Alegre, towards the establishment of Casimiro Tondo as director of the Institute of Biophysics Research; 525 dollars to the Instituto Agronómico do Sul, State of Rio Grande do Sul, for equipment for investigations in soil physics; 3,350 dollars to Raul Cortes, entomologist in the Department of Agricultural Investigations, Ministry of Agriculture, Santiago, for visits to agricultural research centres in entomology in Latin America and the United States; 1,200 dollars to Joaquin Loredo, head of the Federal Extension Service, Ministry of Agriculture and Animal Industry, Mexico, to visit the United States Department of Agriculture and various State extension service centres; 975 dollars to Raul Palacios, representative of the Ministry of Agriculture and Animal Industry, Agricultural Directive Committee, State of Jalisco, Guadalajara, to visit agricultural research centres in the United States; and 7,300 dollars to the Faculty of Veterinary Medicine, University of San Marcos, Lima, for a co-operative project with the Ministry of Agriculture on the study of diseases of the alpaca, under the direction of Dr. Manuel Moro.

The 39 fellowships awarded by the Foundation during the third quarter of 1954 were distributed among the divisions as follows: medicine and public health, 15; natural sciences and agriculture, 10; social sciences, 7; and humanities, 7.

NATIONAL TRUST

ANNUAL REPORT

THE fifty-ninth annual report of the National Trust, presented to the annual general meeting on November 12, records an increase of 8,550 in membership during 1953, and the membership rose further from 44,450 to 47,676 by July 1, 1954, in spite of the increase in minimum subscription for new members from 10s. to £1. For the year ending December 31, 1953, the deficit on ordinary maintenance and administration was about £1,500 compared with deficits of £33,000 and £29,000 for 1951 and 1952, respectively. The position, however, is less encouraging than these figures suggest. The Trust has both a general fund and numerous special funds which can be used only in connexion with particular properties. When such properties show surpluses of income over expenditure, these surpluses are not available to the general funds of the Trust but must be credited to the special trusts concerned, and surpluses of £14,000 were so credited in 1953. On the other hand, deficits on special trust properties have to be met by loans (totalling £15,000 in 1953) from general funds; and taking into account also a similar position which arises with certain properties managed by local committees, the general funds have been called upon to contribute not £1,500 but £22,500 to meet the deficit on ordinary maintenance and administration. It is thus obvious that the natural pull towards the special funds may seriously embarrass the smooth working of the Trust, and the report emphasizes the paramount importance of more 'free' money that can be spent on the general purposes of the Trust and is not tied to one particular property.

The fall in timber prices has also seriously affected the Trust's income, but the Council expresses the hope that the Trust's woodlands will be self-supporting, that in future the property income and membership subscriptions will more than cover the costs of maintenance and administration, that free gifts and bequests will be available to finance improvements, and that the funds for specific purposes will, whenever possible, be used for the purchase or endowment of new properties. Concern is expressed in the report at the inadequate protection afforded to scenery of natural beauty in certain areas by the Town and Country Planning Acts, and it is pointed out that Trust ownership, or covenants with the Trust, still offers valuable protection for unspoilt countryside and, in particular, for stretches of coastal scenery where the pressure for development is usually most vocal and powerful. The Council, while recognizing the necessity for a new orbital road south of London, has strongly opposed the Surrey County Council's choice of route, which is planned to traverse the North Downs, cutting across commons and stretches of country of exceptional beauty, either in the Metropolitan Green Belt or proposed as a conservation area in the National Parks report.

During the year, the General and Specific Purposes Funds have been supplemented by three grants under the Historic Buildings and Ancient Monuments Act, 1953, of £2,100 for repairs to the Treasurer's House, York; £9,000 for repairs to Dunsland House, Devon; and £3,000 for repairs and £1,000 a year for four years for the maintenance of Lyme Park, Cheshire. But at the annual meeting of the Trust, Sir Alan Lascelles, chairman of the Historic Buildings Council for England, said that, while the prospect for historic buildings other than houses is reasonably satisfactory, the outlook for houses generally is sombre. The threat is social rather than financial. Many historic houses owe their preservation solely to the devoted work of their occupants; as that older generation dies out, private maintenance inevitably becomes rarer and public maintenance more and more necessary if such buildings and their contents are to survive. Lord Crawford and Balcarres, presiding over the meeting, referred also to the unnecessary destruction which is taking place and to the damage caused, for example, by the careless siting of electricity generating stations.

CIVIL ENGINEERING TO-DAY

PRESIDENTIAL ADDRESS TO THE INSTITUTION OF CIVIL ENGINEERS

IN his presidential address to the Institution of Civil Engineers, given on November 2, Mr. David Watson directed attention to the wide sphere of interest of the Institution, at its inception in 1818 and during its early years. He quoted the remarks made by Sir John Rennie in 1845, on assuming office, who mentioned harbour construction, railway development, the manufacture of steam ships, drainage schemes, gas illumination, machinery manufacture and mining, as being among the interests of members of the Institution. Many of these pursuits are now the concern of other institutions, that of the civil engineers being concerned to-day almost exclusively with large-scale constructional work. This narrowing of scope is partly a natural process, though it may have been due to a philosophy which appears to have been based upon faith in past experience, rather than in the possibilities of scientific research; but as Mr. Watson pointed out, the Institution remains available to all practising engineers whatever their speciality.

Although Sir John Rennie spoke in 1845 of the "deservedly high place our profession holds in public estimation", Mr. Watson doubts if the public of to-day is given the opportunity of forming an estimate of the place held by the civil engineer, who is too often content to be just a 'back-room boy', of whom the public has never heard. His work is taken for granted; he is too modest and does not seek recognition of the essential part he plays in inspiring, planning and working out all the practical details which eventually give place to the actual direction of the great sources of power in Nature to the use and convenience of man. The public does not know the heavy responsibility that rests on the engineer in spending public money on capital works; it does not realize that his lengthy processes of comparing many ways of doing even a simple job, assessing the life as well as the annual costs, is by no means a mechanical process. It is his experience and judgment which prompt him to recommend only one of the many schemes he has considered. Thereby he assumes the real, if not the nominal, responsibility.

Mr. Watson's own engineering activities have been mainly in the field of public health and sanitary engineering: it was his firm that was responsible for the West Middlesex main drainage scheme with its magnificent sewage disposal works at Mogden. This scheme, since its completion in the mid-thirties, has been an outstanding success and has encouraged the development of biological methods of sewage purification. Such methods are eminently satisfactory for normal domestic wastes, but the biological action may be inhibited by large quantities of industrial waste or even by an excessive concentration of domestic detergents. Mr. Watson suggested that new legislation is long overdue to prevent the penalization of local authorities, owing to these novel and sometimes unpredictable hazards.

BACTERIOLOGY OF MILK AND MILK PRODUCTS

THE autumn meeting of the Society for Applied Bacteriology was held in London on October 26, when recent advances in the bacteriology of milk and milk products were discussed. Dr. J. G. Davis (London) was in the chair. The full papers of the symposium will appear in the *Journal of Applied Bacteriology* (18, No. 2).

W. A. Cuthbert (Leeds), introducing his paper on coli-aerogenes bacteria in dairy water supplies, explained that it was a continuation of an investigation, the earlier part of which had already been reported. Discussing sampling methods in farms and dairies, he directed attention to difficulties and dangers due to fire risks often encountered when carrying out the prescribed flaming of taps in farm buildings. A long series of tests has shown that there is no significant difference in coliform contents of samples taken with and without flaming.

Comparative tests made between brilliant green-bile broth and standard MacConkey broth for detecting *Bact. coli* showed that there is little to choose between the two methods, and hence there was no reason for changing from MacConkey's medium. It did not appear essential to limit the initial incubation period in MacConkey broth to twenty-four hours, as the percentage of positive responses obtained with longer incubation periods, either at 37° or 24° C., did not alter significantly. Incubation of the 44° confirmatory tests, however, could not be reduced to less than forty-eight hours, as there was a 7 per cent increase in positive responses during the second twenty-four hour period. Mr. Cuthbert said that the presence of true *Bact. coli* is generally accepted as an indication of recent fæcal pollution. He also showed that there is an association between the numbers of *Bact. coli* type I, total coli-aerogenes bacteria and fæcal streptococci found. Moreover, except for certain seasonal variations, the 44° and 37° counts vary together. On this basis he doubted whether the 44° confirmatory tests can be justified. There is a natural die-out of *Bact. coli* which varies with temperature and with *p*H of the water. For example, in water from limestone areas *Bact. coli* persists for forty-five days or more, whereas in acid peat soils it dies out in ten days or less.

A review was given by S. B. Thomas (Aberystwyth) of the incidence and classification of coli-aerogenes bacteria isolated at 37° and 30° from farm milk supplies during the past twenty years, in his paper on coli-aerogenes bacteria in milk. The five thousand strains isolated at 37° by fourteen investigators were about equally divided among *Bact. coli*, intermediate and aerogenes-cloacæ types. On the other hand, aerogenes-cloacæ types constituted about 50 per cent of the strains isolated at 30° at Aberystwyth. Only 15 per cent of the strains isolated at 30° from raw milk were 37° negative; the proportions were much higher with strains from soil, water, cereals and ungrazed herbage. It was shown that the coli-aerogenes content of farm milk supplies handled in sterilized equipment did not increase appreciably in 24 hr. at 10°–12°, whereas there was a very marked increase in milk produced under unsatisfactory conditions. Under clean conditions, these organisms were generally not detectable in 0·01 ml. even 24–28 hr. after milking. Mr. Thomas considered selective plating media superior to MacConkey's broth for the determination of the coli-aerogenes organisms content of milk, and said that there is an association between the *Bact. coli* and total coli-aerogenes organisms. On this basis, he maintained that the coli-aerogenes colony count at 30° provides valuable information for advisory work when applied to farm milk supplies within 6 hr. of production. The presence of coli-aerogenes bacteria in apparently normal udders was discussed in relation to the increasing use of penicillin in mastitis control.

The laboratory and field evaluation of chemical sterilizers for dairy farms was discussed by Dr. L. F. L. Clegg (Shinfield). He reviewed the different types of tests devised in past years, and divided them into two groups: 'suspension tests', in which the organisms in aqueous suspension are treated with the disinfectant dilutions; and 'surface tests', in which organisms on various surfaces are treated. From the aspect of practical application, particularly when the highly surface-active quaternary ammonium compounds are being considered, surface film tests are the most suitable, and at the National Institute for Research in Dairying three tests are being developed and undertaken: the laboratory Hoy can test and a surface film test, and finally farm trials. Details of the Hoy can test have been described elsewhere; in principle, the procedure consists of treating infected milk cans for a short period with test disinfectant dilutions, and then examining the effect of the rinse on the keeping quality of normal milk at 22°. This type of test is essentially a comparative one, and a hypochlorite–soda ash solution is used as the standard. In the surface film test, metal strips are inoculated with bacteria, treated for short periods with disinfectant solutions and the surviving bacteria enumerated. The effect of detergency can also be measured by agitating the test solutions gently during the disinfecting period. Experience has shown that dry films are disinfected more slowly than are moist ones, and the rate of disinfection is increased by agitation. Results generally are at a lower level than with suspension tests. For the final farm trials, it is essential to have a control disinfectant running at the same time as the test material, and the efficiency of disinfection is assessed by a combination of colony counts, methylene blue tests, and keeping-quality tests on the milks. In evaluating a new preparation it is important to examine not only its disinfectant properties, but also its effect on rubber and other equipment, and its influence on odour and taste of the milk.

J. D. Ridgway (Stockport) discussed some recent observations on the bacteriology of sterilized milk, and said that faults are generally due to sweet curdling and are more numerous on storage at 23° than 37°. There is an unexpectedly high proportion of failures in winter milks, and this is always due to sporing bacteria which had escaped destruction during the normal sterilization process of heating to 106·5° for 35 min. There is a linear relationship between the logarithm of spore content and the number of samples failing, but there is no relationship between total bacterial content, the thermoduric bacterial content and the spore content of raw milks. Therefore, it is not possible to assess the value of milk for sterilization purposes in terms of good and bad farm milk-production; a good raw milk, or one which pasteurizes satisfactorily, may not give a sterilized milk which will keep well. The source of the spore-forming organisms has not been ascertained with certainty, but they do not appear to be air-borne. Spores have been found in udder milk, presumably originating from straw bedding used. The hygiene of plant is of utmost importance, and steam sterilization is only effective if the plant has been thoroughly pre-cleaned.

The value of the antibiotic nisin in cheese manufacture was described by H. B. Hawley (Yeovil) in a paper on the development and uses of nisin. He described how certain strains of *Strep. lactis* have been found to inhibit lactobacilli under given conditions, and investigations at the National Institute for Research in Dairying led to the discovery of nisin, which is produced by certain strains of the streptococcus. Nisin has a polypeptide structure, and there are several different known types. They have different antibacterial properties, and the types and proportions of each produced depend on the cultural conditions. Because of the particular value of nisin in inhibiting growth of *Cl. welchii*, it has been used effectively in the controlling of cheese, and is particularly valuable with processed cheeses; experimental work is proceeding at present on sweet, low-acid cheeses. Nisin can also be used for control of flat-sour in canning and in the preservation of other foods, particularly meat products. There are numerous and unexpected problems associated with the use of nisin in cheeses because, for example, it upsets the general balance of the bacterial flora and so may produce a cheese of very different texture, odour and taste. Moreover, the presence of certain bacteria appears to nullify the effect of the nisin.

CHARACTERISTICS OF THE BOTTOM ZONE OF LAKES

A SYMPOSIUM on "The Biological, Physical and Chemical Characteristics of the Profundal Zone of Lakes", organized by Prof. V. Tonolli, was held at the Istituto Italiano di Idrobiologia at Pallanza, Lago Maggiore, during July 21–24, under the auspices of the International Union of Biological Sciences with the financial aid of Unesco.

Many advances have been made in recent years in our knowledge of the physical conditions and chemical exchanges at the interface between mud and the bottom water of lakes, thanks to the development of various new techniques, and H. J. Elster (Germany), while emphasizing the services rendered to limnology by A. Thienemann's oligotropic-eutropic classification of lake types, made it clear, using Black Forest lakes and Lake Constance as examples, that a rigid adherence to the classical type concept is not justified, particularly as the chemical turnover in the hypolimnion is to a considerable extent influenced by hydrographical factors. O. Steinböck (Austria) supported this view by his thesis that in the case of upland lakes hydrographical factors are predominant: there are here no lake types but the waters have geographical characteristics, and are best classified as mountain lakes, perennial pools and temporary pools. In those of the second category, daily meteorological changes affect the whole depth of water, so that there is no stable layering. The oxygen content of the bottom water of the upland lakes depends not so much on the productivity of the lake as on organic material washed into it, so that a pseudo-eutropic condition may arise.

K. Strøm (Norway) and B. Dussart (France) dealt with certain little-known phenomena in the hypolimnion. The temperature of the bottom water with maximal density depends on pressure and hence is below 4° C. in the depths of great lakes. The existence of supposed subaquatic springs is often doubtful, for direct observation, as in the Lac d'Annecy, can seldom be made, and their presence is usually deduced from temperature, bottom conditions and faunistic peculiarities; but it can be shown, for example in Lake Geneva, that the phenomena in question may be caused by special hydrographical conditions.

Exchanges at the mud surface were considered by F. Ruttner (Austria), who reported on a striking natural experiment in one of the lakes at Lunz which illustrates the provisional nature of lake types. This 8-metre deep spring-lake is characteristically oligotropic, with a sparse plankton and without thermal and chemical layering. In autumn, however, after dry weather, considerable quantities of lime become dissolved as a result of the decay of the macroflora. The resulting solution of a higher specific gravity flows down into the now inactive funnel of the spring, giving a eutropic zonation, with the disappearance of oxygen, formation of hydrogen sulphide and development of an oligoaerobic plankton. The great extent of mud surface relative to water volume is largely responsible for the very considerable chemical exchanges, with a paucity of oxygen. Such exchanges also take place between water and dissolved colloidal substances, particularly humus. This is an important phenomenon in peaty waters, where the colloids, acting as cation and anion exchangers, control the ionic composition. W. Ohle (Germany) gave a good example of such an action in the case of a magnesium–calcium ratio which was 1 : 2 in electrolyte-poor water and as much as 1 : 7 in water rich in electrolytes.

Sedimentation studies were described by Mrs. W. Tutin (Great Britain) and E. Thomas (Switzerland). The latter has made a quantitative investigation of organic and inorganic sediments in various Swiss lakes, comparing oligotropic with eutropic conditions, considering in particular the nitrogen and phosphorus balance between mud and water in relation to production.

On the faunistic side, H. Järnefelt (Finland) came to the conclusion, from extensive studies of Finnish lakes, that no single factor studied up to the present can account for the nature of populations: a complex of causes must be involved. F. Lenz (Germany) supported this thesis with reference to the bottom fauna of the Lago Maggiore, which varies with meteorological and consequent hydrographical conditions. Contributions to a knowledge of these conditions were made by N. Della Croce and O. Ravera (Italy). The former has investigated oligochaete populations, the density of which depends in part on the particle size of the sediments. Ravera made an experimental study of the quantity of excrement produced in unit time by members of the three oligochæte species of the lake bottom; characteristic differences were found, depending both on species and depth. G. P. Moretti (Italy) made, in the same connexion, a quantitative study of the cases of caddis larvæ, some found as deep as 300 m.

I. Findenegg (Austria) reported on the bottom faunas of lakes in the Kärntner region, which are known to limnologists for the frequent occurrence of the so-called meromictic lake type. It was found that the density of the bottom fauna was at least as great in oligotrophic as in eutrophic lakes. This is due to the low oxygen content of the eutrophic hypolimnion and to the greater vertical range of plankton in the transparent oligotropic waters and consequent greater fall of food material to the bottom.

A particularly interesting faunistic situation from the evolutionary point of view is provided by Lake Ochrida, on which S. Stanković (Jugoslavia) spoke. This pre-Glacial lake has a hypolimnion with a constant temperature throughout the year, and an endemic profundal fauna, with sub-species the nearest relatives of which inhabit the littoral zone, from which they are clearly derived.

Other valuable contributions were made by E. S. Deevey and D. G. Frey (United States) and by H. Züllig (Switzerland). A detailed report of the symposium will be obtainable from the Secretary of the International Union of Biological Sciences, Laboratoire de Physiologie Végétale, Sorbonne, Paris, or from the Istituto Italiano di Idrobiologia, Pallanza, Italy.

R. A. VOLLENWEIDER

THE IONOSPHERE DURING THE SOLAR ECLIPSE OF FEBRUARY 25, 1952

By C. M. MINNIS

Radio Research Station (Department of Scientific and Industrial Research), Slough

DURING the past twenty years, an intensive study has been made of the response of the ionized layers of the earth's upper atmosphere to changes in the intensity of the solar radiation incident on them. Most of the existing fund of knowledge on this subject has been built up from observations of the variations in ionospheric parameters which result from the diurnal and annual changes in radiation intensity caused by the rotation of the earth about its axis and around the sun. The slowness of these changes and the superposed perturbations arising from imperfectly understood large-scale tidal effects lead to difficulties in the analysis of such data.

An eclipse of the sun may be thought of as providing the conditions for a controlled experiment in the ionosphere during which a rapid change in the intensity of the incident radiation takes place but which is not, to a first approximation, further complicated by the normal diurnal changes. Ionospheric observations have, for this reason, been made during solar eclipses on many occasions since the first indirect measurements of Eccles[1] in 1919; but, since the end of the Second World War, few suitable opportunities have occurred of using modern ionospheric sounding techniques in this way. The totality belt for the 1952 eclipse extended from West Africa across the Anglo-Egyptian Sudan to Persia and was, in consequence, fairly accessible. The Department of Scientific and Industrial Research sent two expeditions to Central Africa: one to Ibadan, near Lagos, where the eclipse was partial, and another to Khartoum in the totality belt. At both stations measurements of the height and electron density of the ionospheric layers were made during the eclipse and during the control periods preceding and following it. In addition, observations were made at the Radio Research Station at Slough and at its outstations at Inverness and Singapore, all of which were near the edge of the eclipse area.

E- and *F*1-Layers

The sudden reversal in the rate of change of the radiation intensity during a total or near total eclipse ought, in principle, to make possible the calculation of the effective recombination coefficients which are measures of the rate of decay of ionization in the different layers. For the application of this technique in its simplest form, a necessary condition is that the ionizing radiation should be emitted uniformly from the whole of the sun's disk. Unfortunately, the character of the changes in electron density which are actually observed during eclipses casts considerable doubt on the validity of this assumption. For the 1940 eclipse, Higgs[2] found it to be untenable and attempted to explain his results by assuming that the radiation was emitted from four known areas of calcium flocculi in addition to a component assumed to come from a uniformly radiating disk. The best fit with the observed densities in the *E*-layer was obtained when the intensity of the disk component was put equal to zero; but, as Higgs himself points out, this is not a unique solution. It seems likely that the best fit was not the true one in this instance, particularly since the corresponding results for the *F*1-layer indicated a very large contribution from the disk.

Waldmeier suspected that the *E*-layer measurements made by Rydbeck during the 1945 eclipse might be consistent with the assumption that the ionizing radiation originated in those parts of the inner corona in which the emission line at 5303 A. was strong; a comparison of the ionospheric data with a contour map of the intensity of the 5303 A. line confirmed this[3]. A similar comparison between the ionospheric data obtained at Khartoum in 1952 and the coronal contours based on measurements made at the Pic du Midi tended to support Waldmeier's conclusion, although an unexplained discrepancy remained[4].

A later examination of the Khartoum data for the *E*-layer has shown that the distribution and relative intensities of the sources of radiation can, for this eclipse, be deduced with some precision from the ionospheric data alone, without the need for making any assumptions concerning the positions of the sources. The discrepancy mentioned earlier is then seen to be due to the existence of an intense narrow source on the west limb of the sun, the evidence for which on the coronal intensity map is not decisive. Confirmation of the positions and relative intensities of the sources, as deduced from the Khartoum results, has been obtained by applying a similar method of analysis to *E*-layer data obtained by Piggott[5] at Ibadan two hours earlier (Table 1).

Data on the sources of 5303 A. are given in Table 2. While there is an obvious similarity between

Table 1. Sources of E-Layer Ionizing Radiation, February 25, 1952

Source	Position angle (from N. pole)	Radial extent ($R_\odot$)	Intensity (per cent)
	Khartoum		
Kh 1	240°–320°	0·98–1·0	25
Kh 2	68°	0·64–1·0	8
Kh 3	330°	1·0	3
Disk	—	—	64
	Ibadan		
Ib 1	240°–295°	(*)	25
Ib 2	59°	0·8	8
Disk	—	—	67

(*) Assumed to be confined to the limb as inferred from Khartoum data.

the ionospheric and coronal sources, it would be unwise at present to conclude that they are identical, particularly since a consideration of the area and intensity of the west-limb source (Kh 1, Ib 1) leads to the conclusion that its intrinsic brightness is at least thirty times that of the uniform disk radiation.

The peak of the *F*1-layer at Khartoum was partly obscured by the *F*2-layer, and measurements of its electron density could not be made to the degree of accuracy required to allow the positions and intensities of the *F*1-layer sources to be derived. However, there is no doubt that the uniformly radiating disk model is not capable of accounting for the changes in density which actually occurred. On the other hand, a very good fit between the observed and calculated variations is obtained if it is assumed that the disk model derived from the Khartoum *E*-layer data is valid for the *F*1-layer also. There appears, therefore, to be evidence for believing that a close relation exists between the sources of ionizing radiation responsible for the *E*- and *F*1-layers.

The value of the electron density and its time derivative immediately before totality at Khartoum can be used to determine the effective recombination coefficient (α') for both *E*- and *F*1-layers if it is assumed that during totality the intensity of the ionizing radiation is zero; the values obtained, which are unlikely to be in error by more than 10 per cent on account of errors of measurement, are $\alpha' E = 1 \cdot 51 \times 10^{-8}$ cm.^{3} s.$^{-1}$ (125 km.) and $\alpha' F1 = 8 \cdot 2 \times 10^{-9}$ s.$^{-1}$ ($\sim$ 170 km.).

*F*2-Layer

It is not possible to account for the complex response of the *F*2-layer to an eclipse in terms of the modified Chapman-layer structure assumed for the *E*- and *F*1-layers, because tidal effects seem to play a predominant part at heights greater than 200 km. At Ibadan, the old *F*2-layer which began to form after sunrise but did not have time to attain its daytime density was occulted by a newly formed *F*2-layer which appeared soon after the maximum phase of the eclipse. At Khartoum also, soon after totality, a new layer formed between the *F*1- and *F*2-layers; but, although its density increased very rapidly, it quickly rose in height and merged into the normal *F*2-layer, the density of which had remained quite constant during the eclipse. The sequence of events in the *F*2-layer both at Khartoum and Ibadan, and also during the normal sunrise period, is suggestive of the generation of free electrons at a fairly low level and the vertical transport of this ionization to higher levels where the much lower recombination coefficient results in the very slow rate of decay normally associated with the *F*2-layer.

Table 2. Sources of Coronal Radiation 5303 A., February 25, 1952

Source	Position angle (from N. pole)	Corresponding *E*-layer sources
W. limb (Climax)	225°–330°	Kh 1, Kh 3, Ib 1
E. limb (Climax)	65°–100°	Kh 2, Ib 2
Disk (Pic du Midi)	78° (small area near limb) 103° (small area near limb) Otherwise no outstanding features	Disk radiation

Es-Layer; Corpuscular Eclipse

An unusual and very deep minimum in the critical frequency of the sporadic *E*-layer occurred with a time-lag of about 90 min. after totality at Khartoum. Although no similar change had been observed during the control period, it would be speculative to suggest that it had any connexion with the eclipse.

It is usual to look for possible evidence of a corpuscular eclipse in the ionosphere about two hours before the optical one, but none was observed on this occasion. During the night preceding the eclipse, an ionospheric storm resulted in low and fluctuating values for the electron density in the *F*2-layer, and it is possible that storm effects would have masked any corpuscular eclipse effects which might have been present.

Acknowledgments. This work, a fuller account of which will appear in the *Journal of Atmospheric and Terrestrial Physics*, was carried out as part of the programme of the Radio Research Board; and this account is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research.

MEASUREMENTS OF AGE BY THE CARBON-14 TECHNIQUE

By Prof. HL. DE VRIES and G. W. BARENDSEN
Physical Laboratory, State University of Groningen

THE technique we have used for age determination by means of carbon-14 has already been described elsewhere in detail[1,2]. The essential difference from Libby's technique is the use of a proportional counter filled with carbon dioxide prepared from the sample. Two improvements may be of interest. The first deals with the removal of radon from the carbon dioxide. It was found that the radon originated from the calcium oxide used, obviously by contamination with radium. With another supply of calcium oxide all difficulties were removed and it was checked that radon present in the sample had been removed by the chemical treatment. Further, we have examined various suggestions mentioned in our paper for reducing the background. It was found that an extra anti-coincidence ring did not give any appreciable improvement. The efficiency of one ring is nearly complete; the lower efficiency found by Raeth *et al.*[3] is probably due to coincidences produced by gamma-

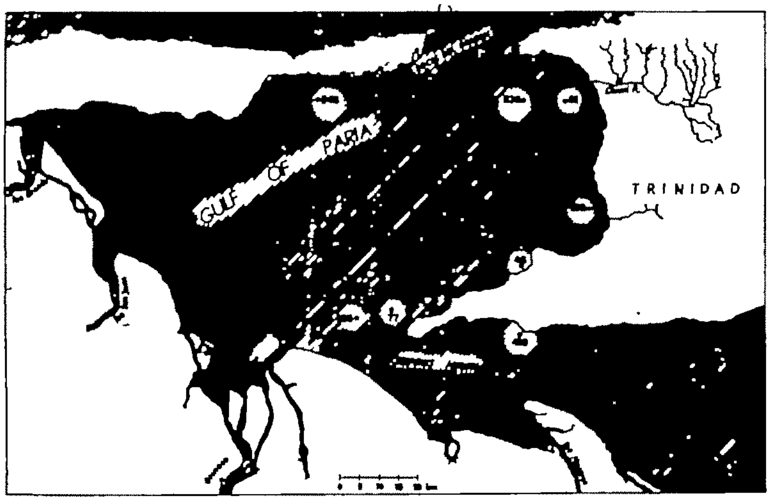

Fig. 1. Gulf of Paria. The numbers of the stations refer to Table 1

Table 1. SHELL SAMPLES FROM THE GULF OF PARIA

Samples from shell beds are marked with an asterisk. Stations 77 and 418 gave only a few scattered shells. 21 and 536 were close together

Station	Depth (cm.)	Age in years	Station	Depth (cm.)	Age in years
21*	0	720 ± 150	77	0	− 130 ± 130
536	70	1,645 ± 160	418	0	60 ± 130
48*	0	655 ± 150	86	63	2,605 ± 240
212*	0	720 ± 200	86	150	3,175 ± 160
548*	10	1,030 ± 140			

rays. An extra layer of mercury proved to be very effective, and we did not find any significant difference between lead and mercury. The background was reduced from 4/min. to 2·64/min. for a layer between the counter and the anti-coincidence ring, and to 3·04 if the extra layer, with the same thickness of 2 cm., was outside the anti-coincidence ring. For special reasons the second arrangement has been used during recent months.

A half-life for carbon-14 of 5,570 years was used for the calculations. The errors given are the statistical errors in the counts, since, according to our experience, no other sources of errors (impurities of the sample, etc.) play any part. Checks on the reliability of the method and remarks on the treatment of the samples are included in the text. Unless otherwise stated, the samples were treated at least with diluted hydrochloric acid. Generally the expected age was not known before the measurement. The following summarizes our results up to July 1954.

Geological Samples

The first group of samples consisted of shells from different parts of the Gulf of Paria (South America) (see Fig. 1). The greater part of the samples contained less than 1 gm. of carbon (which is required for our normal work). A complete discussion of the results in relation with an extensive geological survey is in the press[4], but the general conclusions were as follows. From geological evidence it was anticipated that in more or less recent times the arm of the Orinoco had broken into the gulf. By this 'catastrophe', shell-beds were 'killed' by the fresh water. Indeed, samples 21, 48, 212 and 548 all had the same age. Samples 77 and 418 were expected, for various reasons, to be of recent origin. The rates of sedimentation which can be calculated from the samples at various depths are reasonable.

For the calculations we assumed the specific activity of the shells to be the same as for organic carbon of the same age. Previously it was claimed by Anderson and Libby[5] and by Kulp *et al.*[6] that the activity of the shell carbon was higher, but unpublished measurements of ours give no evidence of any difference; these studies are being continued, but the results for samples 77 and 418 already indicate the activity of recent shells to be the same as for organic carbon. One Tertiary sample has been dated as a check. If no exchange of carbon dioxide had taken place, it would not have contained any carbon-14. Nevertheless, the activity was 3 ± 1·5 per cent of the activity of recent carbon. This, however, is not very significant; moreover, the history of this sample was not known (it came from a museum).

(2) Lowering of the Dutch coast relative to sea-level. This is a scientific problem as well as a practical one. An extensive programme is being carried out on behalf of the committee which studies the possibilities of the closure of the estuaries in south-west Holland. Up to now, about forty samples (peat and shells) have been dated. At the same time, pollen diagrams of the peat are being made. In Fig. 2 we give only a few results which pertain to samples from a large excavation at Velsen (North Holland). The curve demonstrates that the rate of sinking of the bottom was about 35 cm./century some 7,000 years ago, and about 10 cm./century at present. We cannot go into details of the geological problems which have to be solved, such as depth of sample relative to sea-level at time of formation, and disturbance of

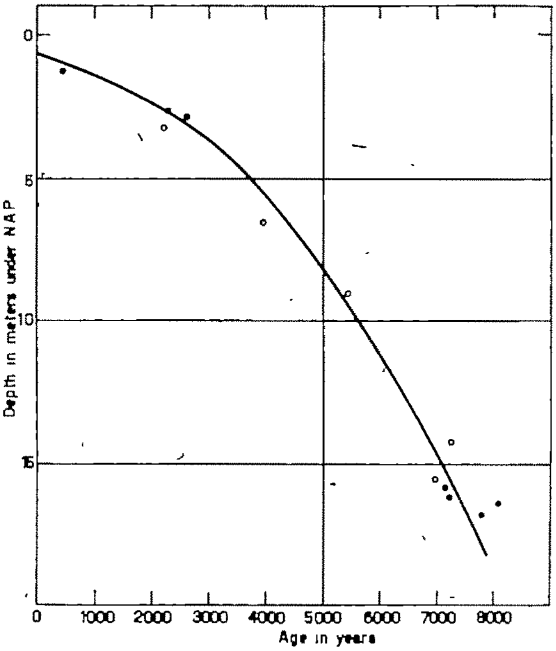

Fig. 2 Lowering of Dutch coast relative to sea-level ●, peat samples; ○, shells. N.A.P. = Ordnance Datum

original position; van Straaten[7] has prepared a preliminary report on these problems.

(3) Bones of domestic animals from underneath lava in south-west Syria, provided by Dr. W. J. van Liere (Food and Agriculture Organization, Damascus). These lava formations are found over a large area and they were expected to be fairly young (from a geological point of view). The present samples came from Kheurbet el Ambachi. Generally, bones are not very suitable for carbon-14 measurements; but part of the present material had obviously been charred in the absence of oxygen. It was nearly black and it contained as much as 25 per cent of carbon. The age was found to be 4,075 ± 160 years.

Archæological Samples

(1) Dried wheat from a Badarian cemetery in Egypt, submitted by Dr. H. Meyers. The grains were scarcely more than thin foils; they were boiled first with hydrochloric acid. The age was found to be 5,110 ± 160 years, which is somewhat younger than expected. We are trying to get a better sample.

(2) Charred wheat, submitted by Prof. Rotmahler. The sample was in a very good condition. It could be considered as presenting the oldest agriculture in Central Europe (*Bandkeramik*). It was found in Westeregeln (close to Magdeburg). The expected age was between 4,000 and 6,000 years, though the lower limit is better in accord with present views. We find 6,200 ± 200 years.

Other samples bearing on the same problem are being assembled, but according to personal information, recent evidence is in support of the present result.

(3) Charred wood from a ceramic band settlement (*frühe Bandkeramik*), submitted by Dr. H. Gross (Bamberg). It was found in Wittislingen, south-west Germany (for details see ref. 8). The sample was separated into two fractions: one fraction was extracted with hot sodium hydroxide and the other boiled with hydrochloric acid and the residue after extraction with hot sodium hydroxide solution examined. The results were 6,090 ± 180 years and 6,000 ± 140 years, respectively. There is no systematic difference; this indicates that no humic acids, etc., had infiltrated. Therefore, we give the average result: 6,030 ± 110 years. For the discussion see also sample (2).

(4) Charred wood from Donderen (Netherlands), submitted by the Biological–Archæological Institute, Groningen (director, Prof. A. E. van Giffen). Dated as Hamburgian. The sample contained few roots, which were selected so far as possible, and it had not been completely converted into coal.

The first measurement, after treatment with cold hydrochloric acid, gave 6,950 ± 160 years. Obviously this age is not compatible with a Hamburgian date, therefore, it was decided to sacrifice the rest of the sample and to separate it into various fractions, as will be described in more detail elsewhere. The results are:

(*a*) Material extracted by hot hydrochloric acid	2,190 ± 300 years
(*b*) Material extracted by hot sodium hydroxide	7,630 ± 140 „
(*c*) Carbon, remaining after (*a*) and (*b*) and after extraction of cellulose	7,365 ± 400 „

The large errors in (*a*) and (*c*) are due to the fact that these fractions contained only about 0·3 gm. of carbon. Obviously the sample did contain some fairly recent material, but nevertheless the age of the rest was still younger than expected. Our conclusion is that the discrepancy cannot be due to an error in measurement.

(5) Charred wood, well preserved, from Een (Drenthe, Netherlands), also submitted by the Biological–Archæological Institute, Groningen. Age found, 7,030 ± 140 years. The expected age was approximately the same as for the previous sample, so that these results suggest a new critical study of the chronology of the Late Palæolithic in the Netherlands.

(6) Four samples of charred wood and one of calcined bone, from a necropolis of thirty barrows at Toterfout-Halve Mijl (North Brabant, Netherlands), submitted by the Biological–Archæological Institute, Groningen (see thesis of Dr. W. Glasbergen[9]).

According to pollen analysis, tumulus 4 was the oldest barrow, dating from about 1500 B.C. We find 3,375 ± 200 years.

Tumulus 8 was important, since it gave information about the burial ritual. It was dated as Bronze Age, about 1100 B.C. We find 3,055 ± 90 years.

Tumulus 1*B* contained an early form of 'Deverel'-urn. According to pollen analysis, it should date from a period close to tumulus 4. We find 3,450 ± 85 years. It follows from this result that the Continental 'Deverel' culture is not related with the later urn-fields, but represents an invasion of British elements. Recent archæological evidence has confirmed this conclusion.

A sample of charred wood from an urn-field, also at Toterfout-Halve Mijl, gave an age of 7,865 ± 240 years. The expected age was some 2,500 years, and this difference is so large that it is beyond doubt that the sample did not come from that urn-field. Indeed, it did not form part of the contents of an urn, but it was found very close to it. It must be ascribed to a Mesolithic settlement; indeed, some flint artefacts were found which were probably Mesolithic.

The urn itself contained some calcined bone, which contained less than 1 per cent of carbon. Moreover, some roots had grown into it which were difficult to remove. Nevertheless, we have made an age-measurement, and find 905 ± 300 years. As might be expected, this is much too young.

(7) Charcoal sample from the primary grave of a Dutch disk barrow, tumulus II, near Postel (Belgium), not far from the Dutch frontier, submitted by Prof. S. J. de Laet (Ghent). We find 3,185 ± 120 years.

It was expected to date from a period between tumulus 1*B* and tumulus 8 described under (6). This is confirmed by our result.

(8) Wood from a Swiss lake dwelling at Thayngen Weier, submitted by Dr. W. U. Guyan (Schaffhausen). The wood was very well preserved. We find 4,735 ± 130 years.

(9) Charred wood from a megalithic tomb (passage grave) at Diever (Netherlands). In agreement with the views of Prof. van Giffen, the age turned out to be 3,850 ± 150 years.

(10) Charred wood, well preserved, from Haule (Netherlands), also submitted by the Biological–Archæological Institute, Groningen. Mesolithic. We find 7,525 ± 200 years.

It had been dated by Libby as 7,900 ± 300, which agrees with our result. Pollen analysis suggested an age of somewhat more than 7,000 years.

(11) Wood from a site at Jemgum (Ost Friesland, Germany). It came from a so-called *Flachlandsiedlung* preceding the first artificial dwelling mounds (*terpen*). In accordance with the age expected by Dr. W. Haarnagel, we find 2,335 ± 70 years.

(12) Charred wood from a Late Neolithic barrow near Hijken (Drenthe, Netherlands). Age expected

by Prof. van Giffen about 1400 or 1500 B.C. We find 3,300 ± 150 years.

(13) Charred wood from a Bronze Age barrow near Grootebroek (North Holland, Netherlands). Age, in accordance with the age expected by Prof. van Giffen (see ref. 10), 3,000 ± 140 years.

(14) Three samples from a three-period barrow in Oudemolen (Drenthe, Netherlands) submitted by Prof. A. E. van Giffen. The original barrow was Late Neolithic, the second period was a barrow with timber circle and, finally, this barrow was covered by another barrow in the Late Bronze Age. In the first and in the last grave charcoal was found, whereas the second period only gave huminiferous sand derived from the original posts. In historical order the results we obtained are: 3,505 ± 125 years, 3,180 ± 120 years, and 3,620 ± 120 years.

Obviously the age for the huminiferous sand is too young. This may be partly due to infiltration of recent huminiferous material from above. Unfortunately, no samples of sand from close to the post holes had been taken as a check. Moreover, the two samples of charred wood from the first and the last period may not give the real age of these two barrows. The dead were probably cremated in a hollow tree; if our samples originated from the central part of this tree—and no special care was taken to avoid that—then an error will be made which is equal to the age of the tree.

(15) Three samples of charred wood from a group of barrows near Wijster (Drenthe, Netherlands). For details see ref. 11. Pollen analysis dated these as "Iron Age". Fragments of bronze artefacts were dated as La Tène (Late Iron Age).

Our results, which are in accordance with this archæological evidence, are: 1,985 ± 150, 2,025 ± 175, and 2,350 ± 300 years. The last sample was re-measured as 2,130 ± 140 years.

(16) Wood from underneath the previous Walburg church at Groningen (Netherlands), submitted by Prof. A. E. van Giffen. For a historical study of the Walburg church see ref. 12. For various reasons this wood sample, consisting of two large blocks, with a cross-section of 50 cm. × 50 cm., was measured several times, in the course of nearly two years. Unless otherwise indicated, new carbon dioxide was prepared each time.

(a) First measurement (May 1952)	850 ± 200	years
(b) Sample from heart of beam	1,200 ± 150	,,
(c) Same carbon dioxide preparation as (b)	1,140 ± 100	,,
(d) Top of block, which might have been infiltrated with recent material	1,060 ± 120	,,
(e) This sample, and the following samples, were taken from a block, sent back by Libby	880 ± 90	,,
(f) Same preparation as (e)	1,010 ± 80	,,
(g) New carbon dioxide preparation	905 ± 65	,,
(h) Material extracted by hot sodium hydroxide	990 ± 140	,,
(i) Material extracted by hot hydrochloric acid	1,035 ± 150	,,
(j) Carbon dioxide prepared from carbon which had been measured by Libby	1,100 ± 200	,,

The average value is about 1,000 years. The deviations from the average are not significant enough to draw conclusions from them. (Denoting the deviation of an individual result by Δ, and the statistical error given in the last column by σ, we find 1·25 for the average of Δ^2/σ^2 (which has to be close to 1). The probability that a value of 1·22 or a larger one happens by chance in a series of ten measurements is about 0·4.) Among others, the result of (h) and (i) indicates that no appreciable amount of young organic material has infiltrated into the sample. We have also prepared pure cellulose from it, but this will be measured with high accuracy in a larger counter.

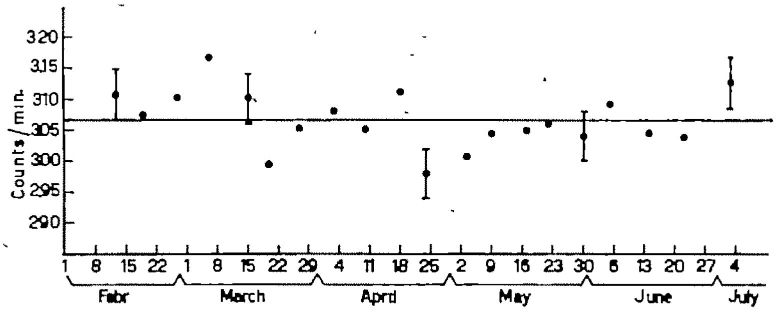

Fig. 3. The background in counts/min. during six months

The main reason why this sample was measured so often was that it was dated by Libby as 2,220 years (± 200). After samples (a), (b) and (c) had been measured, Libby re-measured his first preparation of carbon, but with essentially the same result (3,133 ± 300 and 2,500 ± 270 years). More recently he has measured a new preparation of carbon (from the same block of wood); result, 2,053 ± 345 years.

Finally, the same sample has been used as a cross-check by two other carbon-14 stations. According to private communications, the results were 1,065 ± 130 (Heidelberg, Germany) and 950 ± 80 years (Royal Institution, London). In Heidelberg a carbon dioxide counter is used; in London the counter is filled with acetylene. The origin of the discrepancy between Libby's results and the European results is not yet clear. We mention this, because for sample 8 of this list the agreement was good. Since the wood did not belong to the church itself, we do not know its age exactly. According to ref. 12, however, an age of about 1,000 years does not seem to be unreasonable.

To conclude, we give in Fig. 3 a survey of the backgrounds measured in the past six months. As a rule, the background was measured every week from Saturday to Monday. Fig. 3 does not give significant indications for variations of the background. The average of Δ^2/σ^2 (see earlier comment) is 1·4, whereas the *a priori* probability for this value (or a larger one) is 0·15. Perhaps there is a gradual decrease of the background, but it is too small to be significant. Our normal procedure is to take the average background during the past four weeks, giving double weight to the last two measurements.

We are indebted to the Netherlands Organization for Pure Research (Z.W.O.) for financial support.

Structural Units in Collagen Fibrils

The structure of fibrous proteins has long been a subject of controversy. X-ray and electron microscope evidence has accumulated which suggests that single chains may not run the whole length of the fibril, but that the latter is made up of an aggregation of smaller parts of quite definite size. In collagen the sub-unit has been considered[1] to be a protofibril of size about 640 × 12 A., although recently Schmitt[2] has proposed a unit of about 2000 × 50 A., which he has named 'tropocollagen'. Striations of axial lengths about 210 A. (particularly in developing material[3]) and 70 A.[4] are also observed in electron micrographs of collagen. It is of interest to note that evidence for structure of size approximately 200 A. is found in α-keratin[5] and 230 A. in fibrin[6], although the recurrence of this figure may be no more than coincidental.

We have obtained X-ray diffraction evidence from dry collagen fibres which also suggests that the predominant 640 A. period is divided into sub-units of length about 210 A., although these are not necessarily discrete particles. In native tendon, new X-ray photographs show that the protofibrils are associated laterally into bundles.

In Fig. 1 are plotted the square roots of the observed intensities for the first twelve orders of diffraction of the macro-period (691 A. in this case) against sin θ/λ for dry rat-tail tendon under slight tension. From this plot we have endeavoured to trace out the structure factor of the diffracting unit, and we find that the probable zero positions fit in remarkably well with those for a uniform sphere or ellipsoid of length ∼ 230 A.

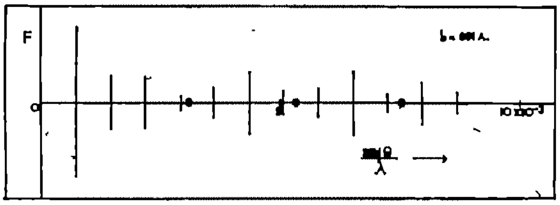

Fig. 1. Square roots of the observed intensities of diffraction orders of the macro-period of dry rat-tail tendon. The circles represent the zero positions for diffraction from a uniform sphere of diameter 230 A.

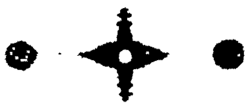
Fig. 2 shows the central region of a photograph of very dry rat-tail tendon taken in an evacuated camera of high resolving power with nickel-filtered copper-$K\alpha$ radiation. Around the central beam can be seen a roughly ellipsoidal halo of diffuse scattering. Applying Guinier's method[7], we have determined the size of the particle which would produce this scattering, assuming it to be an ellipsoid of revolution; we find its axes to be about 200 A. in the fibre direction and about 40–90 A. at right angles. These dimensions correspond very closely with those of the apatite crystallites associated with collagen in bone, which are, moreover, oriented in the same way[8].

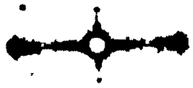
On the other hand, when native collagen fibres are sealed in thin-walled glass capillary tubes before they have dried out, they produce an X-ray fibre diagram, Fig. 3, showing a number of equatorial reflexions of spacings (Table 1) larger than that usually ascribed to the interplanar spacing of single protofibrils. Further, the usual single strong interchain reflexion is now seen to be split up into two components, one on the equator at 12·6 A. and the other just off it on a layer line of spacing of ∼200 A. Attempts to index these reflexions suggest a packing arrangement with dimensions perpendicular to the fibre of:

$$a = 62\text{ A.};\quad c = 76\text{ A.};\quad \beta = 125°.$$

The layer line at 200 A. may correspond to the repeat of a helix or super-helix. There is also some indication of fine structure on the 10 A. layer line.



2



3

VS	VS	M	M	M	W	M	W	S	S

The intensity variation along the equator suggests an arrangement of bundles of about 40–50 A. diameter, each bundle consisting of about seven protofibrils hexagonally packed. The above unit cell would contain two such bundles. On drying, shrinkage is accompanied by loss of order, the bundles eventually scattering independently. Once this stage has been reached the ordered arrangement is not reproduced on wetting, although the individual bundles swell. Irreversible drying phenomena are commonly found in other more truly crystalline proteins.

The overwhelming intensity of the first order of diffraction of the 640 A. period and the asymmetry of the banding as seen on electron micrographs show that this unit is the true repeating entity along the axis of the collagen fibre in its native state.

Evidence has accumulated from a study of low-angle line shapes[9] and from swelling[10] which suggests that within the macro-period there exist alternating regions of greater and less order—interbands and bands respectively—the latter being the sites occupied by stains, such as phosphotungstic acid. We have recently shown[11] that the effects of tension on air-dried fibres are consistent with this picture.

From the improved high-angle X-ray diagram obtainable from fibres held under tension, we have shown that the polypeptide chains within the well-ordered interbands almost certainly have a helical configuration[12].

The diffuseness of the high-angle pattern, however, indicates that these crystalline regions are of small extent, perhaps only 50 A. long. It is not yet clear how the various regions are arranged to give the 640 A. macroperiod with its apparent 200 A. substructure. Nevertheless, the whole system is a highly ordered one, as shown by the sharpness and extent of the low-angle diffraction pattern.

This work was carried out during the tenure of a British Celanese Studentship (A. C. T. N.) and a Nuffield Fellowship (P. M. C.).

Phosphorylation coupled with the Oxidation of Ferrocytochrome *c* by Heart Sarcosomes

Nielsen and Lehninger[1] have recently demonstrated the incorporation of phosphorus-32 into organic phosphate during the aerobic oxidation of ferrocytochrome *c* by rat-liver mitochondria in the presence of adenosine diphosphate, magnesium, versene, antimycin A and inorganic phosphate labelled with phosphorus-32. In the present communication, a net phosphorylation is shown to accompany the same reaction catalysed by rat-heart sarcosomes (mitochondria).

The sarcosomes were isolated in 0·21 *M* sucrose, 0·01 *M* versene, *p*H 7·4, as described previously[2]. The washed sedimented sarcosomes were suspended in 0·021 *M* sucrose, 0·001 *M* versene, *p*H 7·4, to give a concentration of 8·5 mgm. protein/ml., and the suspension was kept at 0° C. for 30 min. to allow oxidation of residual substrates. Four volumes of recently boiled and cooled glass-distilled water were then added, so that the sarcosomes were now suspended in a medium 1/50th the tonicity of rat blood. This hypotonic pretreatment of the sarcosomes was suggested by the work of Lehninger[3] on the phosphorylation coupled with the oxidation of reduced diphosphopyridine nucleotide by liver mitochondria. The concentration of the final suspension medium giving maximum phosphorylation was found in experiments which will be published elsewhere.

Table 1. PHOSPHORYLATION COUPLED WITH THE OXIDATION OF FERROCYTOCHROME *c* BY RAT-HEART SARCOSOMES.

See text for reaction mixture and procedure. *p*H of reaction mixture, 7·4; 14·4 min. at 22° C.

	Cell 1	Cell 2		Cell 3

Hexose monophosphate (μmoles)					
Initial	0·022	0·022		0·022	
Final	0·058	0·244		0·057	
Δ	0·036	0·222		0·035	
Δ (corr.)	—	0·186		0	
$\Delta P/\frac{1}{2}\Delta$ cytochrome *c*	—	0·34		0	

A 1-cm. spectrophotometric cell (cell 2 in Table 1) contained 90 μmoles phosphate, 60 μmoles glucose, 3 μmoles versene, 120 μmoles fluoride, 0·6 μmole adenosine monophosphate, 0·6 μmole adenosine diphosphate, 127 units hexokinase[4] and 1·6 μmoles cytochrome *c* (89 per cent reduced, 11 per cent oxidized) in a total volume of 2·8 ml. A reference cell (No. 1) contained all these ingredients except the cytochrome *c*. Magnesium chloride (0·1 ml. of 0·15 *M*) was added to each cell and the optical density at 600 mμ of cell 2 read against that of cell 1 until a steady reading was obtained (this is necessary because of the formation of a slight turbidity when the magnesium is added). At zero time, 0·1 ml. of the diluted sarcosomal suspension (containing 0·19 mgm. protein) was added to each cell, and the oxidation of the ferrocytochrome *c* followed by measuring the increase of optical density at 600 mμ. After 14·4 min., when 1·10 μmoles of ferrocytochrome *c* had been oxidized (the cytochrome *c* was now 20 per cent reduced, 80 per cent oxidized), trichloroacetic acid was added to each cell and the hexose monophosphate formed determined according to the method previously described[5].

The small amount of hexose monophosphate found in the reference cell is mainly due to the non-oxidative phosphorylation of glucose by adenosine diphosphate catalysed by myokinase and hexokinase[4]. Phosphorylation derived from the oxidation of traces of substrates in the sarcosomal preparation will also be included in the hexose monophosphate found in this cell. The hexose monophosphate found in cell 2 minus that found in cell 1 represents the phosphorylation coupled with the oxidation of ferrocytochrome *c*. The corrected value (0·186 μmole) is many times greater than the sensitivity of the analytical method (about 0·01 μmole) and corresponds to a ratio of phosphorus to ½ (ferrocytochrome *c*) of 0·34. This ratio is about the same as the ratio of phosphorus – oxygen atoms (0·32) obtained when ascorbic acid was oxidized by the same preparation in the presence of catalytic amounts of cytochrome *c*. It is likely, then, that the phosphorylation obtained with ascorbate[6] occurs in the reaction between cytochrome *c* and oxygen.

The preparation of ferrocytochrome *c* used was made by reduction of a stock solution of cytochrome *c* by hydrogen in the presence of platinum black, the hydrogen then being removed by a stream of nitrogen and the platinum by centrifugation. Cell 3 in Table 1 was an additional control in which the stock solution of cytochrome c (11 per cent reduced) was used. No phosphorylation beyond that found in the control cell 1 was found in cell 3, showing that the prior reduction of the cytochrome c was entirely responsible for the corrected phosphorylation measured in cell 2.

The demonstration that phosphorylation can be coupled with the oxidation of ferrocytochrome c is in complete agreement with the findings of Nielsen and Lehninger[1]. From the point of view of the mechanism of the phosphorylation, it is important to establish whether the ratio of phosphorus to ½ (ferrocytochrome c) is equal to or exceeds 0·5 (corresponding to a ratio of phosphorus to oxygen molecules of 1). Our results to date suggest that the ratio in heart sarcosomes might not exceed 0·5, but it is quite possible that improvements in technique will result in ratios approaching 1. With liver mitochondria, Nielsen and Lehninger[1] have obtained ratios between 0·44 and 0·86 for this reaction. Liver mitochondria oxidizing ascorbic acid in the presence of catalytic amounts of cytochrome c also yield ratios of phosphorus to oxygen atoms approaching one[7].

This work was carried out on behalf of the Agricultural Research Council.

Infra-red and Ultra-violet Absorption Spectra of Proteins in the Solid State

The potassium bromide pressed-disk technique for the determination of infra-red spectra in the solid state was first developed in our laboratories during the period 1947–49 under contract with the U.S. Air Materiel Command, but, as restricted information, was not formally published at that time[1]. The method has since been used by Stimson[2] and independently by Schiedt[3,4]. The technique has been successfully applied by us to a number of proteins, and the purpose of this communication is to direct attention to this application. A major advantage of the technique lies in the ability to determine both infra-red and ultra-violet absorption of the same protein sample under identical conditions.

The technique was briefly as follows: 'A.R.' grade potassium bromide, ground to 200-mesh in a mullite mortar, was dried at 110° C. Samples of purified proteins, also ground to 200 mesh, were mixed to give the desired concentration (usually 1 per cent) and the mixture was passed several times through a 200-mesh sieve. 200 mgm. of mixture was placed in a cylindrical 0·5-in. (1·27-cm.) steel die which was enclosed in a larger cylinder connected to a vacuum pump and McLeod gauge. The system was evacuated for approximately five minutes at 40 microns pressure; lower pressures were not more advantageous, but evacuation was necessary or the disks clouded and fractured from occluded gases after pressing. With the system still being evacuated, pressure, usually 150,000 lb. per sq. in., was applied for a few seconds to one minute; longer pressing offered no advantage. Air was then admitted. The clear disk was removed from the die and weighed. A companion disk of pure potassium bromide was also made. Our apparatus could be electrically heated, but heat was not useful in the pressing of potassium bromide. It was helpful in pressing materials of lower melting point such as thallium halides or silver chloride. The maximum variation in weight between disks was 30 mgm. in 200 mgm., but it was possible to hold the variation to not more than 5 mgm. in a given series. Maximum variation in thickness in such a series was about 0·0025 cm. in disks with an average thickness of 0·0635 cm. As also shown by Stimson[2], these differences are compensated, and uniform distribution is demonstrated by the fact that the quotient, optical density/per cent times weight, is reasonably constant.

Preliminary measurements were made on several mechanical properties of the pressed disks of potassium bromide as compared with the crystalline halide. For this purpose a 1-in. die was used. Young's modulus of the pressed potassium bromide was $1·17 \times 10^{11}$ dynes/cm.^{2}, as compared with $0·76 \times 10^{11}$ dynes/cm.^{2} for a grown crystal. Pressed potassium bromide had a coefficient of linear expansion of $38·8 \times 10^{-6}$ cm./cm./deg. C., as compared with $35·0 \times 10^{-6}$ cm./cm./deg. C. for a grown crystal (Baxter[5] reports $37·0 \times 10^{-6}$ cm./cm./deg. C.). Tensile strength of the pressed halide averaged 1,000 lb./sq. in. compared with 400 lb./sq. in. for grown crystals.

The proteins used in these studies were crystalline bovine serum albumin and chymotrypsinogen (gifts of the Armour Laboratories); and egg albumin, cytochrome c, and lyophilized whole rabbit serum prepared in our laboratory. The infra-red spectra were obtained with a Perkin-Elmer *IR* Spectrophotometer, Model 21, through the courtesy of Dr. Seymour Levine and Mr. H. J. R. Stevenson, of the Sanitary Engineering Center, U.S. Public Health Service, Cincinnati. The ultra-violet spectra were obtained with a Beckman Model *DU* quartz spectrophotometer.

Typical infra-red spectra are shown in Fig. 1. All proteins, of course, display the expected bands in the 3 μ, 6 μ and 6·5 μ regions. Bovine serum albumin, egg albumin and cytochrome c have a shoulder at about 3·25 μ; this shoulder is slightly evident in whole rabbit serum but is absent in chymotrypsinogen. All show bands of varying intensity at about 3·42 μ. All except chymotrypsinogen (which shows at most a slight shoulder) have a band at 6·9 μ. All have a band at 7·2 μ; this is particularly pronounced for chymotrypsinogen and is shifted slightly to 7·15 μ. Egg albumin and rabbit serum show separate bands at 7·7 μ and 8·1 μ, but the first of these is barely discernible in cytochrome c and in chymotrypsinogen; the absorption is broad over this region for bovine serum albumin, with only slight suggestions of two peaks. Slight bands are present in the 8·55 μ–8·65 μ region for all proteins except chymotrypsinogen. Slight bands are also present for all proteins in the

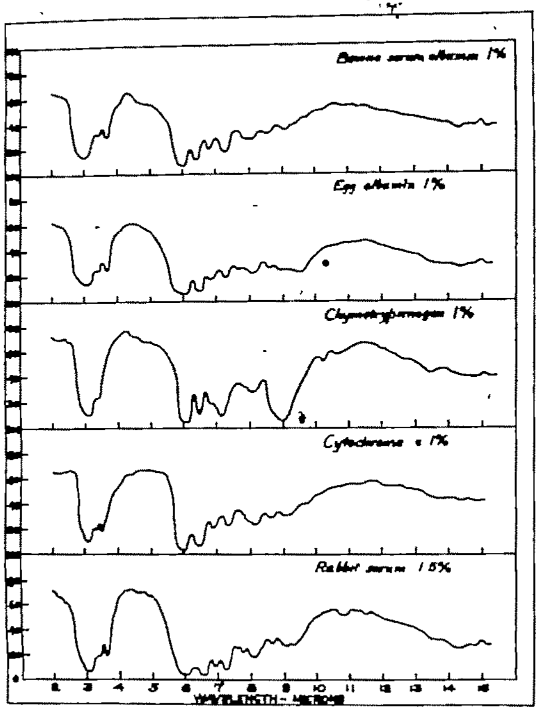

Fig. 1. Infra-red absorption of proteins in potassium bromide disks

9·0 μ region, but this absorption is very pronounced for chymotrypsinogen. With slight differences in detail, these spectra compare favourably with the corresponding ones reported by Klotz[6] for cytochrome *c* and bovine serum albumin in films on silver chloride, and they appear to resemble closely those reported by Fong *et al.*[7] for crystalline human serum albumin.

The ultra-violet spectra of the solid proteins were compared with the spectra of solutions in 0·1 *N* hydrochloric acid and in 0·1 *N* sodium hydroxide. The spectra of egg albumin in the solid state and in acid exhibited a peak at 278 mμ, whereas in base the peak was shifted to 290 mμ. Bovine serum albumin in the acid solution had a peak at about 278 mμ and in basic solution at 290 mμ; in the disk, although there was a shoulder at 280 mμ, peak absorption occurred at 265 mμ. Chymotrypsinogen appeared to be relatively unaffected by *p*H; solutions in acid and base both showed absorption peaks at 280 mμ. The disk had a shoulder at 280 mμ but a more pronounced peak at 272 mμ. Cytochrome *c* in solution displayed an acid peak at 275 mμ and a basic peak at 290 mμ. The disk had a selective absorption, but not pronounced peaks, at 262 mμ and 280 mμ. All the ultra-violet absorptions thus far described can be attributed, of course, to aromatic amino-acids. None of the proteins absorbed appreciably at wavelengths longer than 300–320 mμ, with the exception of cytochrome *c*, which absorbs at longer wavelengths because of its prosthetic group.

We wish to make special acknowledgment to the following in our Division of Physics, who were active with one of us in various aspects of the early work which led to the present technique: George F. Embshoff, Cornelius H. Jansen, Daniel Fuentes, Frank Burns and William Thielking; and D. A. Wells, Department of Physics, University of Cincinnati. We also acknowledge a grant-in-aid from the National Cancer Institute, National Institutes of Health, U.S. Public Health Service.

Origin of Glycine and Serine in Bakers' Yeast

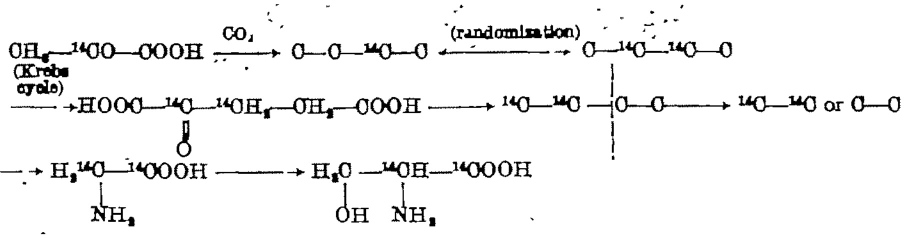
THE ready interconversion of glycine and serine in biological systems has been well recognized for several years. Somewhat less attention has been paid to the origin of this pair of compounds from other metabolites, although evidence has been presented[1] to indicate that serine may arise prior to glycine, through transformations involving pyruvate or other C_3 compounds.

Work in this laboratory has been focused upon the conversion of pyruvate-2-^{14}C to amino-acids in bakers' yeast. Using this substrate and the yeast samples described previously[2–4] for examination of other amino-acids, the distribution of isotope was observed for the serine and glycine isolated from the yeast hydrolysate. Both compounds were obtained in pure form by adsorption of the hydrolysate on a 'Dowex-50' column and fractional elution according to the method of Stein and Moore[7]. Threonine and alanine were removed by separation on cellulose powder columns. Purity of the samples was checked by paper chromatography.

It will be noted from Table 1 that the isotope patterns in carbons 1 and 2 of serine and glycine are very similar, with carbon 2 only slightly higher in activity than carbon 1. This confirms the ease of interconversion of these two compounds. However, when alanine from these yeast samples was degraded, it was found to be labelled primarily in carbon 2 (67 per cent in the aerobic culture, 90 cent per in the anaerobic). The alanine side-chains of phenylalanine[3] and tyrosine[4] also showed preferential labelling in carbon 2, as might be expected if these units arose from the pyruvate administered. It is therefore evident that the pathway from pyruvate to serine is less direct, and must involve one or more steps which permit isotope equilibration in positions 1 and 2 of serine.

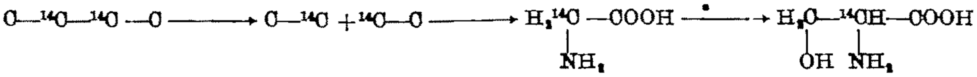
This condition could be satisfied if serine were formed through glycine, by forward operation of the Krebs cycle, followed by α,β-cleavage of a C_4-acid. The glycine carbon atoms would thus correspond to carbons 2 and 3 of α-ketoglutarate or glutamic acid, which were, as shown previously[5], equally labelled in this yeast sample. Sequence *A* illustrates the suggested formation of glycine from pyruvate and its conversion to serine:

(A)

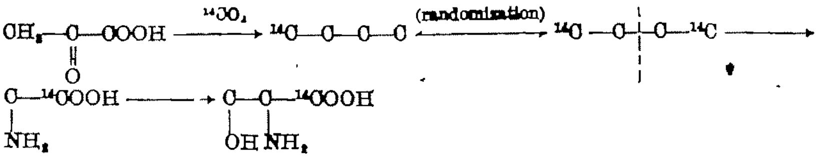


(B) via fumarate or succinate:

(B)



(C)



Reverse operation of the cycle (scheme *B*) would, on the other hand, provide preferential labelling in carbon 2 of glycine.

The slightly higher isotope concentration in this position of both glycine and serine (Table 1) may suggest a partial contribution from this pathway.

Fixation of carbon-14 dioxide with non-isotopic pyruvate is also being examined in this yeast. Under these conditions, glycine and serine become labelled within one hour, shortly after aspartic acid becomes radioactive, whereas alanine remains unlabelled during periods up to five hours. This again supports the conclusion that serine probably does not arise directly from pyruvate. Degradation of serine reveals the isotope mainly in the carboxyl group. This could be expected from equilibration of the C_4-acids formed, followed by their conversion to glycine (scheme *C*), since simultaneous operation of the cycle (scheme *A*) would in this experiment provide only unlabelled glycine and serine.

Table 1. DISTRIBUTION OF CARBON-14 IN GLYCINE AND SERINE UTILIZING $CH_3{}^{14}COCOOH$

Amino-acid	Carbon atom	Radioactivity			
		Aerobic		Anaerobic	
		c.p.m. × 10^{-4}*	per cent of total	c.p.m. × 10^{-4}*	per cent of total
Glycine	Total	1 81	100	1·75	100
	1. COOH	0 85	47	0·70	40
	2. CH_2NH_2	0 96	53	1·05	60
Serine	Total	2 84	100	1·18	100
	1. COOH	1·16	41	0·49	42
	2 $CHNH_2$	1·60	57	0 55	48
	3. CH_2OH	0 06	2	0·11	10

* Specific activity (total) is expressed as counts per min. per m.mol amino-acid; the activities of individual carbon atoms are counts per min per m.mol. carbon. All values are given in terms of the undiluted amino-acids.

It is concluded that the serine ⟷ glycine interconversion in bakers' yeast is fed primarily from C_4-acids through glycine, in contrast to the situation in animal metabolism, where serine is thought to arise directly from pyruvate.

This research was supported by contract No. *AT*(45-1)-301 from the Atomic Energy Commission. A portion of the work described is taken from the thesis presented by one of the authors (J. W. D.) for the degree of doctor of philosophy at Oregon State College, 1954.

Electrophoresis of Human Red-Cell Stroma

IN an attempt to provide a chemical basis for an understanding of the morphological appearance of human red cells and of the changes in red-cell morphology in various hæmatological disorders, we have fractionated red-cell stroma preparations by electrophoresis. Three lipid-containing protein fractions have been separated, two of which migrate readily in veronal buffer at *p*H 8·6 ($\mu = 0{\cdot}1$). Red-cell stroma was prepared initially in the manner described by us[1], but in addition was washed twice with 0·1 *M* potassium dihydrogen phosphate and three times with distilled water. A stromal extract obtained with 0·2 *M* ammonium hydroxide and containing 18 μgm. of tyrosine equivalents of protein[2] was then subjected to paper electrophoresis[3].

Fig. 1 shows the electrophoretic mobilities of the fractions as determined on the basis of azocarmine *B* and sudan black binding resulting from staining after electrophoresis. The dye concentrations were estimated colorimetrically and are expressed as optical densities.

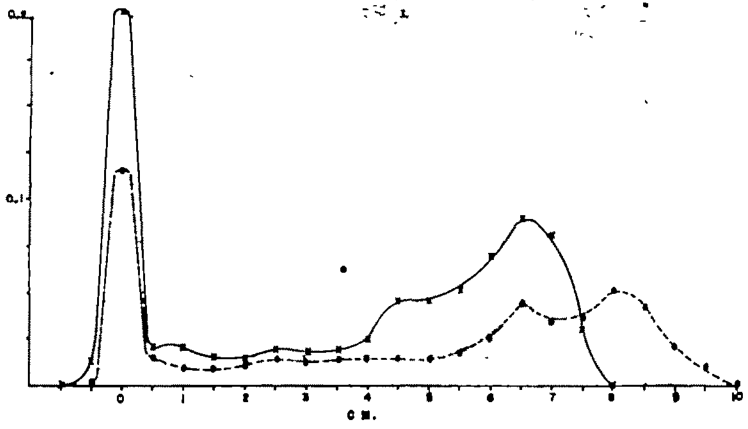

Fig. 1. Electrophoretic mobility pattern of red-cell stroma. Solid line: azocarmine binding; broken line: sudan black binding

Similar studies were carried out on a preparative scale by zone electrophoresis on cellulose slabs using Whatman No. 1 standard grade cellulose powder. These fractions were examined serologically and it was found that the blood group substances *A* and/or *B* were located in the slowly moving fraction in high concentration. *Rh* substance is present in the crude stroma extract but, on electrophoresis, neither fraction was sufficiently strongly inhibitory to the *Rh* antibody to indicate the fate of this substance. Details of these studies will be published elsewhere.

This communication is based in part on work performed under contract with the United States Atomic Energy Commission at the University of Rochester A.E.C. Project. Two of us (J. R. A. and T. A. J. P.) are indebted to Dr. G. H. Whipple and Dr. L. E. Young for providing facilities for this research.

Renal Excretion of 17-Ketosteroids by Members of some Ethnic Groups living in Malaya

We have recently studied the 24-hr. renal outputs of 17-ketosteroids by normal adult males belonging to some of the well-defined, civilized ethnic groups living on Singapore Island and in the Federation of Malaya. The groups for which complete data have been obtained (a sample of twenty subjects was taken from each ethnic group) are Chinese, European and Malay. The Chinese were all of recent Southern Chinese origin, most of the Europeans were of recent English origin and most of the Malays were of recent 'Peninsular' origin. Work on other subjects belonging to both civilized and uncivilized groups has yet to be completed and evaluated. Meanwhile, the existing complete data are discussed briefly (Table 1).

The ages of the subjects were all within a range (17–46 yr.) over which the 17-ketosteroid excretion of normal male Europeans has been found to be relatively independent of age[1,2], and we are of the opinion that only a small fraction, if any, of the differences revealed in Table 1 can be attributed to disparities in the ages of the subjects.

The observations afford three pair-comparisons of the 17-ketosteroid excretions. Employing the arithmetic values and (in view of the non-homogeneous variances) having recourse to the Cochran and Cox[3] *t* statistic to test the significance of differences between the arithmetic means, it is found that the differences between the Chinese and European means and between the European and Malay means are probably of high statistical significance. However, the intra-sample distributions of 17-ketosteroid values approximate to 'log-normal'[4] rather than 'normal' form, and the validity of the test is therefore impaired. As the variances of the $\log_{10}$ (values) are fairly similar, 'Student's' *t* test has been applied to test the significance of differences between the means (namely, the $\log_{10}$ (geometric means), these latter being: Chinese 8·7, European 15·3, Malay 7·3), using for the purpose a pooled estimate of variance (0·02068). The comparisons yield: Chinese and European, $t = 5{\cdot}40$, $P < 0{\cdot}001$; Chinese and Malay, $t = 1{\cdot}66$, $P > 0{\cdot}05$; European and Malay, $t = 7{\cdot}05$, $P < 0{\cdot}001$, the probability (P) levels being taken from tables[5] of *t*. Differences as large as those observed in the first and the third pair-comparisons would be extremely unlikely to arise in random sampling from homogeneous populations, a finding which confirms that indicated by the less satisfactory examination mentioned earlier.

Little work of this type has yet been performed. It has been observed[6], however, that mature African and English males appeared to have very dissimilar excretions of 17-ketosteroids; and our results, rather similar to those of Barnicot and Wolffson[6] so far as the European subjects are concerned, likewise suggest

Table 1. Renal Excretion of 17-Ketosteroids by Samples of Twenty Adult Males

Each sample was drawn from a separate ethnic group. 17-Ketosteroids in urine estimated by the procedure (ref. 8) recommended by Warren (ref. 9), and creatinine by the method of Folin (ref. 10). Means and standard deviations of $\log_{10}$ (values) are shown in parentheses in columns 2 and 4, respectively

Ethnic group	24-hr. 17-ketosteroid excretion			24-hr. mean creatinine excretion (gm.)	Mean wt. (kgm.)	Mean age (yr.)
	Mean (mgm.)	Range (mgm.)	Standard deviation (mgm.)			
Chinese	9·2 (0·940)	3·9–17·5	3·26 (0·154)	1·45	53·3	23·2
European	16·0 (1·185)	10·5–27·9	4·82 (0·125)	1·87	73·5	31·8
Malay	7·8 (0·864)	4·4–14·9	2·89 (0·154)	1·42	57·1	32·4

that the excretions of other ethnic groups are lower. However, the two samples studied by Barnicot and Wolffson exhibited distinctly similar creatinine excretions, whereas our European subjects excreted appreciably more creatinine (on the average) than did our Chinese or our Malay subjects. Again, our European subjects were (on the average) appreciably heavier than those of the other ethnic groups—Barnicot and Wolffson have given no comparison of weights.

Our work suggests that there may be a correlation between 17-ketosteroid output on one hand and creatinine output and/or weight on the other. In this connexion it is pertinent to recall that evidence has earlier been found[7] of a correlation between the 17-ketosteroid and creatinine outputs of children of European origin.

A more rigorous statistical examination of our results (complicated by the fact that the distributions of some variates, but not all, are more nearly 'log-normal' than 'normal') is in progress. It is hoped that the investigations may (among other things) suggest a clinically more useful estimate of '17-ketosteroid status' than is afforded by the absolute 24-hr. excretion values themselves or is suggested by the correlation observed by Nathanson, Miller, Towne and Aub[7].

Neurohypophysial Control of Follicular Maturation in the Domestic Fowl

EVIDENCE from several sources[1–4] supports the view that the discharge of ovulation-inducing hormone from the hypophysis of the domestic fowl is mediated by a nervous mechanism, as in the rat[5]. The interval from 'excitation' for the release of the hormone to ovulation has been estimated to be of the order of 8–14 hr.[4,6,7]. In the present communication we wish to direct attention to results indicating that ovulations in the hen may be suppressed by the interruption, long before the estimated hour of release of the ovulation-inducing hormone, of processes presumably associated with maturation of the ovarian follicle.

The birds used, conditions of their maintenance, and experimental procedures have been described recently[4]. Hens selected for test were ovulating in 3-day 'closed' cycles[4]. The first or C_1 ovulation in such cycles occurs at about 6.00 a.m., the second or C_2 ovulation at about 10.30 a.m. on the next day. Ovulation does not take place on the third day of the cycle, but does so at 6.00 a.m. of the day thereafter to initiate a new cycle. The interval between C_1 and C_2 ovulations is thus about 28·5 hr., that between C_2 and C_1 ovulations about 43·5 hr. In the main body of experiments, the suppressing or 'blocking' agents were injected 38 hr. before expected C_1 ovulation, or 5–6 hr. following the preceding C_2 ovulation. The hens were palpated at appropriate hours to determine the occurrence or non-occurrence of ovulation on the day of expected ovulation or on the day thereafter. When the injected agent interfered with normal feed or water intake, the birds were forcibly fed and watered.

The suppressing agents included phenobarbital sodium, diallylbarbituric acid ('Dial'), pentobarbital sodium ('Nembutal'), the adrenergic blocking agent *SKF*-501, and the anticholinergic drug, atropine sulphate. Solutions of the barbiturates were prepared according to Fraps and Case[4], of *SKF*-501 and atropine sulphate as described by Zarrow and Bastian[8]. No attempt was made to determine the conditions of maximal suppressing action of the several agents.

Table 1. SUPPRESSION OF C_1 OVULATION BY BARBITURATES AND 'BLOCKING' AGENTS ADMINISTERED 38 HR. BEFORE EXPECTED OVULATION

Treatment			No. of hens injected	Ovulations suppressed	
Agent	Route*	Quantity		No.	Per cent
Phenobarbital sodium	Sc.	100 mgm./kgm.	10	9	90
'Dial'	Im.	80 ,,	10	8	80
'Nembutal'	Sc.	60 ,,	11	6	55
SKF-501	Im	10 ,,	9	7	77
Atropine sulphate	Ip.	150 mgm./hen	9	6	67

* Sc., subcutaneous; Im., intramuscular, Ip, intraperitoneal.

Results of injections 38 hr. before expected C_1 ovulation are recorded in Table 1. The significance of these results becomes apparent on comparing the effects of the same agents following administration at about 14 hr. before expected C_1 ovulation, that is, when injected for effect on the neural component of the mechanism causing release of the ovulation-inducing hormone specifically. Phenobarbital at 14 hr. suppresses few or no ovulations[1], in contrast with 90 per cent at 38 hr. 'Dial' and 'Nembutal' actually induce ovulation prematurely in some hens injected at 14 hr. before expected ovulation[1], whereas at 38 hr. the same barbiturates act only as suppressing agents.

A single injection of *SKF*-501 at 14 hr. suppresses 30–40 per cent of expected ovulations (unpublished observations), as against 77 per cent at 38 hr. The incidence of ovulations suppressed by the single 38-hr. injection of *SKF*-501 compares favourably with the results of two injections used by Zarrow and Bastian[8] for direct blockade of ovulation-inducing hormone release. These authors also reported that atropine sulphate suppressed C_1 ovulation following administration of the drug at hourly intervals for 12 hr., beginning some 8–10 hr. before expected ovulation. A single injection of the same agent at 38 hr. yields results of the same order.

The suppression of C_1 ovulation by barbiturates and 'blocking' agents injected 38 hr. before expected ovulation indicates almost certainly the blockade of a nervous mechanism controlling some essential pre-ovulatory process. The direct suppression of the release of ovulation-inducing hormone is obviously improbable. It is suggested that the nervous activity in question controls the secretion of hypophysial hormone (or hormones) required for maintenance and function of the maturing ovarian follicle.

A fairly extensive body of circumstantial evidence might be marshalled in support of the view that the hen's maturing follicle secretes progesterone (or a physiologically equivalent steroid) and that this hormone, rather than œstrogen, 'excites' the mechanism for release of the ovulation-inducing hormone. On this view, the hen's maturing follicle may be said to undergo luteinization prior to release of gonadotrophin for its ovulation. Pre-ovulatory progesterone has been demonstrated in mammals[8], but apparently only following release of the luteinizing hormone for ovulation. The postulated pre-ovulatory luteinization of the hen's follicle may imply the existence of nervous and hypophysial functions usually associated with ovulation and post-ovulatory luteinization in the rat[6]. Further observations bearing upon this hypothesis will be presented elsewhere.

Note added in proof. The adrenergic blocking agent, 'Dibenamine', administered 38 hr. before expected C_1 ovulation but otherwise in accordance with procedures of van Tienhoven *et al.*[5], suppresses ovulation in more than 90 per cent of injected hens. This drug should therefore be included with effective agents listed in Table 1.

Thanks are due to Dr. A. E. Heming, of the Smith, Kline and French Laboratories, Philadelphia, for 'Dibenamine' and *SKF*-501, and to the Research Department of Ciba Pharmaceutical Products, Inc., Summit, New Jersey, for 'Dial'.

Research on the Mammals of South Africa

A RECENT paper by Dr. L. Harrison Matthews[1] has raised several interesting points regarding the biological study of mammals in Africa. Most stress was laid on big game studies, and the fact that they must be done before the game has disappeared owing to the advance of civilization. In South Africa two big game animals, *Equus quagga* Gmelin, the true quagga, and *Ozanna leucophaea* (Pallas), the blue antelope, are already extinct as a result of indiscriminate hunting, while many other groups like the bontebok (*Damaliscus pygargus* (Pallas)) are approaching extinction.

While the activities of hunters have to some extent been curbed by severe legislation, large numbers of game animals have been destroyed in the Union of South Africa and still are being decimated in the Rhodesias and Bechuanaland in combating the tsetse fly. Furthermore, here as elsewhere, wherever game stands in the way of agricultural development, the game inevitably goes. Hence it truly becomes necessary to learn all that is possible of the animals concerned before it is too late. At the same time, as pointed out by Harrison Matthews[1], where game is being destroyed, splendid opportunities exist for the collection of skeletal material for study purposes, and scientific institutions should be given the chance to avail themselves of these opportunities.

The biological study of small mammals is equally important, but from a different point of view. Here the stress is not on the danger of extinction, which for the smaller forms is not very real, but on the various scientific and economic problems that small mammals, and particularly rodents, bring in their train. Possibly the most important of these is the danger of plague, which is transmitted by small mammals. Another is the economic importance of rodent epizootics, for example, the destruction of trees in forestry plantations in the Sabie area (Transvaal) in 1951 and the recent (1953) invasion of *Mastomys* (multimammate mouse) in the Springbok Flats area of the Transvaal.

The problem is further complicated by our incomplete taxonomic knowledge of our mammal fauna. Two recent books on this subject, by Roberts[2] and Ellerman, Morrison-Scott and Hayman[3], both fail to present a true picture of this, the first as a result of intensive splitting, the second by extreme lumping together of groups of doubtful affinities. As pointed out by Handley[4], "some portions of the world are still in the 'exploration and cataloguing' stage as far as mammalogy is concerned". This is very true of South Africa, and while this remains the case, biological knowledge of our fauna is bound to progress little. On the other hand, of course, to complete the circle, taxonomy cannot produce "a sifted, sorted, and simplified nomenclature" (Handley[4]) without a more detailed biological background than at present exists.

A certain amount of work on mammal biology has been done. The splendid work of the late Dr. C. J. van der Horst has already been mentioned[1]. Furthermore, the Plague Research Laboratory of the South African Institute for Medical Research has for a number of years been carrying out researches on the taxonomy and biology of plague-carrying rodents. Examples of this are to be found in the work of Davis[5,6], Oliff[7] and others.

A Zoological Survey was brought into being in 1936 by the Division of Veterinary Services and did valuable work on the carriers of animal-borne disease (see Thomas and Kolbe[8]). Unfortunately, this project died an untimely death, and nothing similar has since been attempted.

At the present moment efforts are being made to form a Division of Biological Survey, and various groups and individuals (see Meester[9]) have stressed the need for a body of this nature. However, these efforts are handicapped first by the lack of official support and secondly by the shortage of trained workers. It seems, therefore, that some time will elapse before concrete results can be expected. Delay, however, is inadvisable and may be fatal. As Harrison Matthews has pointed out[1], the advance of civilization in Africa will inevitably result, in a relatively short period, in the destruction of the larger elements at least of the mammal fauna outside the game reserves. It is essential to learn what can be learnt while there is the time and the material.

At the same time, without belittling the isolated work done by the various groups and individuals mentioned by Harrison Matthews and here, there can be little doubt that the interests of science would be better served by a broader, more realistic approach. Even the Biological Survey mentioned above would have a restricted, national scope.

It seems, therefore, that the problem should be approached on an international basis, similar to that of the International Red Locust Control Board. The only organization with a more or less international scope in Africa at the moment is the Scientific Council for Africa South of the Sahara, which has already shown its willingness to co-operate in conducting studies on African mammals. In view of this it would seem highly desirable for the Council to interest itself in organizing a body for the purpose of conducting and correlating biological research on African mammals.

Fine Structure of Exocrine Cells of the Pancreas

A cytological study has been carried out on exocrine cells of the pancreas of the mouse with the aid of the electron microscope. The tissue was taken from animals aged two to three months and fixed in osmic acid buffered[1] to a pH of 7·4. It was then embedded in *n*-butyl methacrylate and sections about 400–800 A. thick were cut. Similar tissue, also fixed in buffered osmic acid, was embedded in gelatine for sectioning and examination by light microscopy in order to compare the effects of osmium fixation with those obtained by other fixatives employed in previous studies[2,3].

One of the most conspicuous objects identified in pancreas cells by means of the electron microscope was the Golgi apparatus (Fig. 1). In each cell this usually consisted of several groups of three or four vacuoles in close association with the zymogen granules. The vacuoles were apparently closely pressed together, but were separated from each other by a dense transverse membrane about 450 A. thick (Fig. 1, *tm*). This membrane joined with a limiting membrane (Fig. 1, *lm*) which was often similar in appearance to the transverse membrane but which separated the vacuoles from the surrounding cytoplasm. In some instances the limiting membrane was thicker (about 900 A. in diameter) on one side of the vacuoles than on the other side. In other cases it was a tubular or bilamellar structure about 1500 A. wide containing cristæ and granules dispersed along its length. In the region of the Golgi vacuoles numerous granules about 650 A. in diameter, sometimes containing a minute single dense particle, were seen scattered in the adjacent cytoplasm. These observations are consistent with the view[3] that the Golgi apparatus, as seen in sections 4–5 μ thick, is a three-dimensional canal-like organelle with transverse striæ passing across its lumen.

The mitochondria were not of uniform appearance but tended to fall into three categories: (1) tubular bodies about 3 μ long and about 0·3 μ in diameter containing many fine cristæ close together; some of these possessed lateral or terminal 'buds'; (2) tubular objects about 2·5 μ long and about 0·3 μ in diameter with a thickening at one end and bearing distinct cristæ; (3) tubular inclusions about 3 μ long and about 0·3 μ in diameter showing evidence of vacuolation and poorly developed cristæ; the surface of these bodies was indented in the midline in such a way that they bore a superficial resemblance to *Paramecium*. These three types of mitochondria may actually represent different functional conditions of a single type or be indicative of age changes[4].

Objects identified as prozymogen bodies appeared to originate from mitochondria by a process akin to budding and contained cristæ. In the Golgi zone it was observed that such bodies contained some of the 650 A. granules mentioned above and that few cristæ were present. Other prozymogen bodies contained a dense inner core which was regarded as the first sign of a developing zymogen granule. Finally, a micrograph was obtained which left little doubt that the fully developed zymogen granules are sometimes dehisced from the prozymogen bodies. These observations support the view[3] that prozymogen bodies originate from mitochondria and receive some contribution from the Golgi zone before completing the synthesis of zymogen.

The zymogen granules were seen as dense oval or spherical bodies (Fig. 1, *z*) sometimes with an irregular spiky outline. Some of them contained very small granules (about 200 A. in diameter) which may be related to the granules found within the prozymogen bodies. The density of the zymogen granules was not attributed to their osmophilia, since in the gelatine sections, which were examined by the light microscope, it was seen that they were relatively non-impregnated.

The appearance of the endoplasmic reticulum[1] varied considerably from cell to cell. It is believed

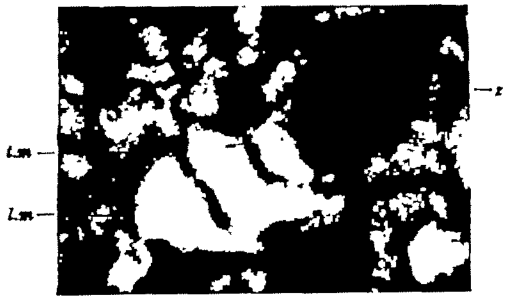

Fig. 1. Golgi apparatus, with transverse membranes (*t.m*) and limiting membrane (*l m*), close to zymogen granules (*z*). Electron micrograph. × *c* 25,000

that this was not due to vagaries in fixation but probably reflected the condition of cells in different phases of the secretion cycle[3]. In some cells the reticulum was represented by many parallel lamellæ or canaliculi, whereas in other cases only a vestige of this structure was retained and the cytoplasm resembled an open network.

Examination of the nucleus showed that along the nuclear membrane were many granules of the kind described by Ludford[5]. At first sight the nucleolus appeared to consist of an anastomizing opaque reticulum, but careful examination revealed that the strands of the reticulum actually consisted of granular material.

When osmium-fixed, gelatine-embedded sections were examined with the ordinary light microscope and the results compared with those obtained in previous studies[2,3] it was found that: (1) buffered osmic acid renders the tissue so brittle that thin (3–4 μ) sections can rarely be obtained; (2) it preserves lipids; (3) there is no specific impregnation of mitochondria, Golgi apparatus or prozymogen bodies by the osmium. It may be emphasized here that the fact that lipids are preserved in osmium-fixed gelatine-embedded preparations does not signify that they are retained in *n*-butyl methacrylate-embedded material. It is quite probable that some lipids are lost in preparing material for the electron microscope, and that vacuoles in such material actually represent the site of this substance.

Chemical Composition of Uredospores of Wheat Stem Rust (*Puccinia graminis tritici*)

ONE approach to the problem of controlling wheat stem rust is the study of the chemistry of the parasite. As part of an investigation into the chemical nature of wheat stem rust, a preliminary examination has been made of uredospores of *Puccinia graminis tritici*. When uredospores of mixed races are subjected to the action of 72 per cent sulphuric acid for 24 hr. at room temperature (23° C.) and then heated with 2 *N* sulphuric acid in a sealed tube immersed in boiling water for 16 hr., D-glucose, D-mannose and D-arabitol are liberated. These three substances were identified by paper chromatography using ethyl acetate – acetic acid – water (3 : 1 : 3)[1]. By means of a cellulose column and the same irrigating solvent, enough of each of these three components was separated in order to provide crystalline derivatives thus:

D-Arabitol pentaacetate, m.p. 75° C., $[\alpha]_D^{25}$ + 37·4° (chloroform)
D-Mannose *p*-nitroanilide, m.p. 221° C., $[\alpha]_D^{25}$ – 404° (pyridine)
1,2,3,4,6α-D-Glucose pentaacetate, m.p. 108° C., $[\alpha]_D^{23}$ + 105° (chloroform)

The literature shows that glucose and mannose have been identified in uredospores of wheat stem rust by paper chromatography, but no crystalline derivatives were prepared and it was not possible to state whether they were the D- or the L-sugars[2]. So far as we are aware the work reported herein constitutes the first proof of the identity of D-glucose, D-mannose and D-arabitol in uredospores. The five-carbon sugar alcohol, D-arabitol, is seldom encountered in natural products, although it has been reported in lichens[3].

Quantitative analyses, using the method of Dubois *et al.*[4] for the sugars and of Lambert *et al.*[5] for D-arabitol, indicated that the uredospores contained 2 per cent D-glucose, 19 per cent D-mannose and 3 per cent D-arabitol on a dry-weight basis.

Work is in progress to ascertain the nature of the carbohydrate compound(s) from which the above three substances are derived.

We thank Prof. Fred Smith (University of Minnesota) and Prof. J. G. Dickson (University of Wisconsin, Madison) for their interest in this work.

Seed Dressings for the Control of Wheat Bulb Fly

GOUGH[1] has referred to the serious damage caused by wheat bulb fly (*Leptohylemyia coarctata* Fall.) in Great Britain in 1953 and discussed various means of preventing or reducing attacks. Of the possible methods of chemical control, seed dressings seemed worthy of investigation; previous experiments had given conflicting but usually negative results. One of the possible reasons for this was the length of time between the date of sowing and the egg-hatching period, and we therefore laid down two field-experiments to study this time-factor. The seed dressings were: (1) a standard proprietary one containing 1 per cent of an organo-mercurial fungicide applied at 2 oz./bush.; (2) 40 per cent gamma-BHC containing 0·8 per cent of an organo-mercurial applied at 3 oz./bush.; (3) 40 per cent dieldrin containing 0·6 per cent of an organo-mercurial also applied at 3 oz./bush.

There were two sowing dates, an early one in October or November, and a late one in December or January. The six treatments, that is, three seed dressings × two sowing dates, were randomized among four blocks in exp. *A* (peat soil) and three blocks in exp. *B* (acid peat). Both fields had previously been cropped with potatoes and were known to have a very high population of wheat bulb fly eggs of the order of 3–5 million per acre.

Table 1

	Exp.	Early sowing A–13.XI.53. B–20.X.53			Late sowing A–6.I.54. B–17.XII.53			S.E. 5 per cent
		Control	Dieldrin	BHC	Control	Dieldrin	BHC	
No. attacked shoots in millions/ac. (approx. equivalent to larval count)	*A* *B*	1·90 2·20	1·60 2·30	1·53 2·35	1·01 1·17	0·73 0·77	0·50 0·95	— —
Per cent attacked shoots	*A* *B*	43·1 53·7	34·3 53·8	34·1 55·7	79·6 96·4	65·0 74·9	37·3 73·9	— —
Per cent attacked shoots (angular transformation)	*A* *B*	41 47	36 47	36 48	64 79	54 62	38 61	4·7 13·0

In both fields by April the early-sown wheat had tillered well, masking the heavy larval attack. In exp. *A* in the late-sown (January 6) plots the gamma-BHC plots were uniformly good, the control plots uniformly poor and the dieldrin plots intermediate. In exp. *B*, where the late sowing was on December 17, the BHC plots were moderate, the controls a complete failure and two of the three dieldrin plots intermediate.

In May the same visual differences were still apparent on exp. *A*, except that the dieldrin plots were much improved relative to the controls, which were a complete failure; the early-sown plots continued to grow away from the attack. On exp. *B*, all the late-sown plots were failures and the attack had caused considerable thinning of the early-sown plots.

Plant samples were removed from five (exp. *A*) or seven (exp. *B*) unit areas on each plot at the end of March. The unit areas were two adjacent and parallel 1-ft. lengths of row. These samples were stored in a refrigerator until they could be examined and the numbers of attacked shoots and larvæ counted.

As only one larva survives in any one shoot[2] the absolute number of larvæ on the late-sown plots (where no tillering had taken place) was much smaller than on the early-sown plots. The results (Table 1) are therefore best compared on a percentage basis, and the analysis of variance has been made on an angular transformation.

Thus it is clear that the treatments have had little or no effect on the early-sown wheat, but have had a marked and significant effect on the late-sown treatments on field *A*. The differences on field *B* are not significant. Whether the lack of effect (or reduced effect) on field *B* is due to the different conditions or to the somewhat earlier date of sowing is not certain, but the latter is a reasonable assumption.

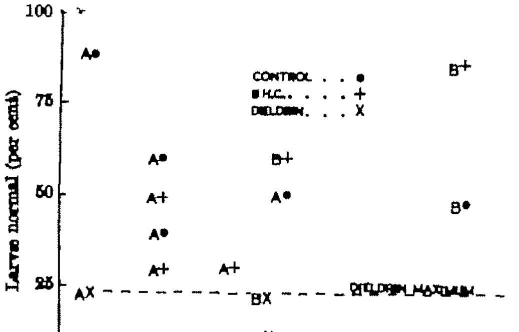

Fig. 1. Condition of wheat bulb fly larvæ from late-sown plants treated with BHC or dieldrin seed-dressing. The numbers of larvæ examined for exp. *A* are much greater than for exp. *B*

During a previous trial it had been noted that there was a slightly higher proportion of dead larvæ inside plants grown from aldrin- and dieldrin-treated seed than from BHC-treated and untreated seed, and the condition of the larvæ was therefore recorded in the present trials. Unfortunately, the length of time taken in dissecting and examining many thousands of plants rendered a direct comparison of the relative proportions of dead larvæ unreliable, and the effect is most clearly seen in a graph (Fig. 1), when the percentage of apparently normal larvæ for each of the later-sown treatments is plotted against the number of days elapsing between collection and examination. The remaining larvæ were either dead or classified as moribund or abnormal.

It is clear that dieldrin is having a marked effect on the larvæ in the plants, though the effect of BHC is less certain. It was, however, noted during the examination of the plants that many of those in the late-sown BHC treatments had a minute hole or tear in the first leaf consistent with the attempt of a larva to enter, though there were no signs of larvæ having been in these plants. It would appear, therefore, that the main effect of the BHC had been to prevent entry of the larva, and that of dieldrin had been to kill the larva after entry. This would explain the poor appearance of the dieldrin plots in the early stages and their subsequent improvement. As the larvæ were not killed until some time after entry, it seems likely that the dieldrin was taken up by the plant. This apparent systemic effect of dieldrin has been independently confirmed by workers in the Department of Insecticides and Fungicides at Rothamsted.

Insecticidal seed dressings are widely applied to cereals, and their use is being rapidly extended to other crops; but knowledge on their mode of action is meagre. Lange *et al.*[3] showed that wireworms died when confined in soil with lima beans dressed with BHC. Dogger and Lilly[4] suggested a repellent action, and this appears to be the general assumption. Seed treatment with insecticides can be regarded as a special method of soil application, and Starnes[5], Howe[6], Shapiro[7] and Kozlova and Dvortzova[8] have recorded mortality of insects feeding on or in various parts of plants growing in soil treated with BHC and other chlorinated hydrocarbons. In view of all these observations, it would seem desirable to study the mechanism of the protection afforded by seed treatments.

The seed dressings were prepared by the Department of Insecticides and Fungicides, Rothamsted Experimental Station, and we are indebted to Dr. C. Potter of that Department for this facility and for reading this communication in draft. We also acknowledge the help of several colleagues and of Mr. W. R. Green and Mr. T. A. Saul, who provided

the sites and carried out all the cultivations. This work is supported by a grant from the Agricultural Research Council.

Polarization of Radio Echoes from Aurorae

NOTABLE variations in the polarization of radio echoes from aurorae have been observed at Saskatoon (52·1° N., 106·6° W.), using frequencies of 56 and 106·5 Mc./s. Theories of very high-frequency radio propagation predict the maintenance of the transmitted state of polarization under normal ionospheric conditions. An examination by Moore[1] of amateur radio transmissions by 'auroral propagation' indicated that this was also the case when aurora was present. Observations by Bowles[2] confirmed this conclusion, although exceptions occurred when aurora was overhead. More recently, Harang and Landmark[3], in reporting on back-scatter echoes during aurora, mentioned that 35 Mc./s. echoes were sometimes completely depolarized and sometimes nearly plane polarized, and that 74 Mc./s. echoes were plane polarized in the same sense as the transmitted signals. The Saskatoon observations are apparently the only ones that have been made so far where it has been possible to verify the auroral origin of the echoes[4].

The apparatus consisted essentially of two radar units transmitting horizontally polarized signals toward magnetic north on frequencies of 56 and 106·5 Mc./s., and a multiple antenna system designed to detect the angle of arrival and various types of polarization of the resulting echoes from aurorae. The 56 Mc./s. receiving antennae consisted of a high, horizontally polarized Yagi; a low, horizontally polarized Yagi; a low, vertically polarized Yagi; and a low, circularly polarized antenna which could be alternated rapidly between right-handed and left-handed circular reception. A common receiver was used for these antennae, a radio-frequency switch alternately connecting the two antennae of a selected combination to the receiver. The first two antennae were designed primarily to determine the angle of arrival of the echoes[4]. Only a horizontally and a vertically polarized Yagi were used for reception of 106·5 Mc./s. echoes. The received signals were presented on a cathode-ray tube as a range-amplitude display. The traces for each antenna combination were shifted vertically in synchronism with the radio-frequency switching. The displays were photographed using short time exposures. To obtain the polarization ratios plotted in Figs. 1 and 2, the amplitude ratios obtained from the photographs were normalized using a factor calculated from the horizontally and vertically polarized propagation patterns of the antennae. This normalization factor is a function of angle of arrival and hence of range.

Observations on 56 Mc./s. during the period from December 1953 to August 1954 showed a large variation in the polarization ratios of the echoes. A strong degree of de-polarization was exhibited by a large proportion of the echoes. Fig. 1, based on the measurement of 489 56 Mc./s. echoes, is a histogram of the occurrence of echoes with various polarization ratios. For the 'finite ratio' group (66 per cent) of the 56 Mc./s. echoes, the most probable polarization ratio (horizontal to vertical component of field-strength) was 1·1 and the mean power ratio was 3 decibels. The 'infinite ratio' group (34 per cent of the echoes)

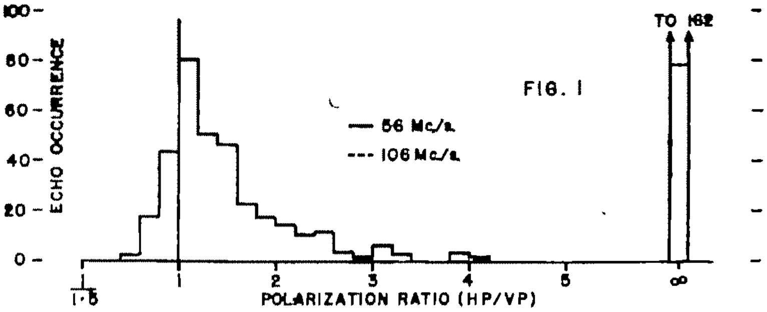

FIG. 1

FIG. 2

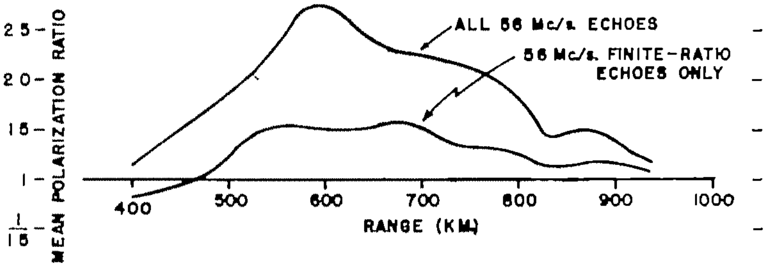

FIG. 3

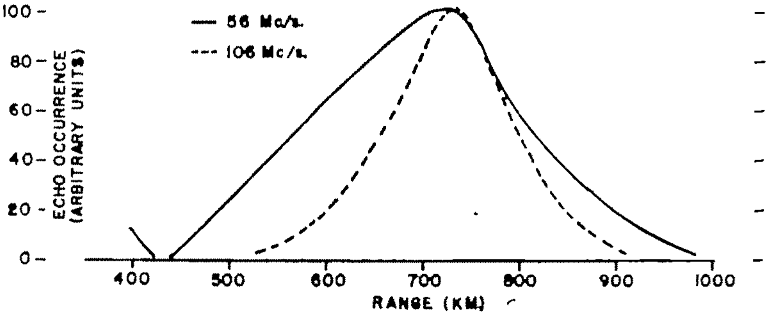

were substantially plane polarized in the sense of the transmitted signals. The mean power ratio, including both types of echoes, was 5 decibels. An exact division of the echoes into the two types was not possible because the relatively small signal-to-noise ratios (0–26 db.) made precise measurement of amplitude difficult, and the transition from one classification to the other was not sharply defined. The presence of polarization ratios of less than unity is believed to be due to experimental error. Observations with the circularly polarized antenna showed approximately equal amplitudes for left- and right-handed senses of rotation. The ratio of the circularly polarized antenna signal to the horizontally polarized antenna signal was practically constant. The polarization ratios (horizontal to vertical) sometimes differed widely for echoes occurring simultaneously but at different ranges. Also, the polarization of the echoes was observed at times to change from the plane to the de-polarized state, or vice versa, within a period of minutes.

Fig. 2 shows the variation of the mean normalized polarization ratio as a function of range. There appears to be a significant increase in the polarization ratio in the range 500–900 km. The region indicated by these ranges approximates to the meridian section of the Chapman echo surface[5], where the radar line of sight is perpendicular to the earth's magnetic field at E-region heights.

All observations of the polarization of 106·5 Mc./s. echoes (June–August 1954) have shown only plane polarization in the same sense as the transmitted signals. The seventy-eight echoes recorded in this period are shown in Fig. 1 by the dotted line. Instantaneous polarization relationships and relative occurrence of 56 and 106 Mc./s. echoes could not be inferred from the observations, since simultaneous display of polarization effects on the two frequencies was not possible with the apparatus employed. However, the change-over from one frequency to the other was accomplished within a few seconds, and general relationships could be determined.

Fig. 3 is a plot of echo occurrence against radar range. The shape of the 106 Mc./s. distribution is only approximate because of the much smaller number of echoes available. Apparently the 106 Mc./s. occurrence is largely restricted to the range interval in which high polarization ratios are obtained on 56 Mc./s. The occurrence of echoes is controlled by a number of factors: the propagation pattern of the antenna, the latitudinal variation of auroral occurrence, the earth's curvature, and the attenuation effect which limits occurrence of echoes to low angles of elevation. Correlations of polarization ratios with types of echoes (diffuse and discrete), or with types of visible aurora (homogeneous and rayed structures), have not yet been attempted. Two processes which could cause de-polarization of the signals are the magneto-ionic effect and multiple scatter within the reflecting region. Of the two, the latter seems the more likely. If the primary reflexion is by coherent scatter from long trails of ionization lying along the lines of the earth's magnetic field, aspect attenuation will limit the back-scattered signal to regions satisfying the criterion of perpendicularity. Multiple scatter will cause a broadening of the scattering polar diagram and thus permit echoes to be obtained from somewhat beyond the Chapman echo surface. In addition, over-dense volumes in the ionized region[4] will themselves possess omnidirectional polar diagrams and thus further extend the echoing region. This condition should occur oftener at the lower frequency.

This work has been made possible by financial assistance from the Defence Research Board of Canada and by loan of equipment from the U.S.A. Air Force Cambridge Research Center.

Titanium Nitride and Titanium Carbide as Semiconductors

It is well known that titanium nitride shows the electric properties of a typical metal[1]. In fact, the specific resistivity ρ is lower than that of titanium metal itself. We have re-examined these experiments, using van Arkels's technique[2] of deposition from the vapour phase for the preparation. Our results, given in Table 1, agree fairly well with those of the earlier investigators.

By the same method we have prepared layers of titanium nitride (TiN) on sintered aluminium oxide and quartz glass. The thickness of these layers varied between 1 and 25 μ. The layers on aluminium oxide have essentially the same properties as the titanium nitride deposited on tungsten wire. The small differences may be due to the uncertain thickness of the layer or perhaps to small impurities. The layers on quartz glass, on the other hand, show completely different electric behaviour, which resembles that considered typical for semiconductors. The specific resistivity at room temperature is $10–10^3$ times as high as for the samples on tungsten and aluminium oxide. In a certain temperature-range the temperature coefficient of the resistivity is negative. The position and height of the maximum depends on the particular kind of sample. The resistivity at 800° C. is almost the same for all layers on quartz glass. It is still higher than that of titanium nitride on tungsten or aluminium oxide. The Hall coefficient R has a negative sign and is essentially the same for both kinds of samples.

The structure of layers from both sides after removing the base materials has been examined by X-ray diffraction. We found no difference between the metallic and semiconducting titanium nitride. No impurities could be detected, and the lattice constant

Table 1. Electric Properties of Different Samples of Titanium Nitride

Sample No.	Base material	ρ 20° C. (Ω cm.)	ρ 800° C. (Ω cm.)	Temp. coeff. of ρ between 700° and 800° C	Hall coeff (R) (cm.³/coulomb)
1	Tungsten wire	$1·65 \times 10^{-5}$	$5·82 \times 10^{-5}$	$+3·2 \times 10^{-4}$	
I_{Al}	Aluminium oxide	$4·6 \times 10^{-5}$	$1·2 \times 10^{-4}$	$+2 \times 10^{-3}$	$-1·2 \times 10^{-4}$
IV	Silica	$1·4 \times 10^{-3}$	$1·8 \times 10^{-4}$	-2×10^{-3}	
I*	Silica	$3·9 \times 10^{-4}$	$1·6 \times 10^{-4}$	-4×10^{-4}	$-1·3 \times 10^{-4}$

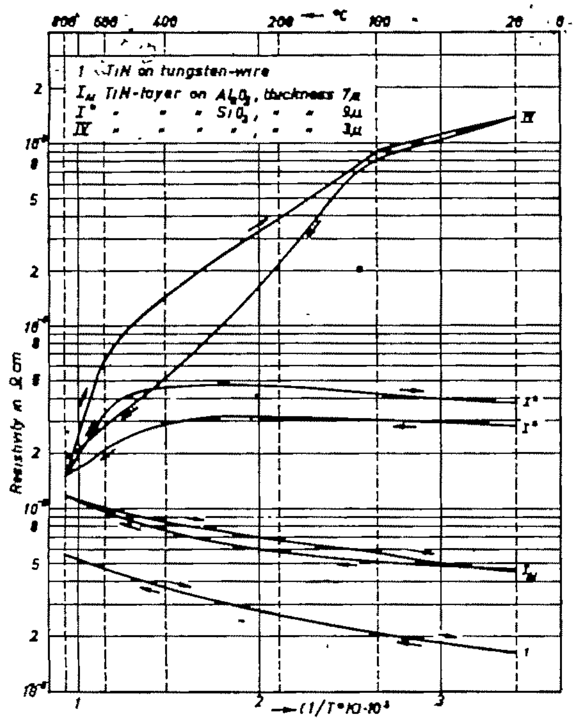

Fig. 1

has exactly the same value in both cases (4·2346 ± 0·0002 A.). Fig. 1 shows the relation of the specific resistivity to temperature for typical samples. Some numerical results are given in Table 1. Essentially the same behaviour has been observed for titanium carbide and mixed crystals of titanium nitride and carbide.

A full description of the experiments and the theoretical discussion will be published elsewhere.

Point Source and Sink in a Parallelepiped

THE potential distribution in a parallelepiped arising from a point source and sink is of practical importance in the measurement of the thickness of plates and tubes[1,2], and the electrical conductivity of semiconductors[3]. A common practical arrangement employs four collinear equi-spaced contacts: current I is passed between the outer pair, and the potential difference V between the inner pair is measured. If the contacts are aligned centrally parallel to the longest side 2α of a rectangular block of material, its width being 2β and its thickness γ in units of the electrode spacing, the conductivity is given by the triple series :

$$\sigma = \frac{I}{\pi V} \sum_{-\infty}^{\infty} \sum_{-\infty}^{\infty} \sum_{-\infty}^{\infty} (-1)^{n} \Big\{ [(2n\alpha + 1)^2 + 4m^2\beta^2 + 4r^2\gamma^2]^{-1/2} - [(2n\alpha + 2)^2 + 4m^2\beta^2 + 4r^2\gamma^2]^{-1/2} \Big\}$$

The difficulty in computing this series lies in the slow convergence of the single series :

$$s = \sum_{-\infty}^{\infty} [(n^2 + x^2)^{-1/2} - (n^2 + y^2)^{-1/2}],$$

when x and y are large. Warren[2] applied the Euler–Maclaurin summation formula to obtain approximations, and other workers have offered no alternative formula.

Although it is not difficult to show that

$$s = \int_{-\infty}^{\infty} \left[\frac{H_0^{(1)}(xt) - H_0^{(1)}(yt)}{e^t - 1}\right] dt,$$

and thence to obtain the alternative expansion

$$s = \left\{2 \log(y/x) + 4 \sum_{n=1}^{\infty} [K_0(2\pi nx) - K_0(2\pi ny)]\right\},$$

this result does not appear to have been published hitherto.

It is a simple matter to reduce triple summations to a calculable form by means of this transformation, and the result may be readily extended to series involving higher inverse powers of $(n^2 + x^2)$ and $(n^2 + y^2)$. Such series are important in solid-state crystal theories, where they have usually led to tedious approximations, although recently a more powerful approach has been described[4].

Dielectric Increment of Sodium Alginate as a Function of Polyion and Counter-ion Concentration

A NUMBER of linear polyelectrolytes—acid as well as basic—give high dielectric increments in aqueous solution, when compared with less asymmetric proteins and simple dipolar ions.

The sodium salt of alginic acid (poly-β-*d*-mannuronic acid) has been shown recently to have dielectric properties in aqueous solution similar to the other polyelectrolytes studied, namely, high dielectric increments which show anomalous dependence upon concentration (see Fig. 1), dielectric dispersions at radio-frequencies which are strongly dependent upon concentration, decrease of increments and change of dispersions with addition of small amounts of simple electrolytes, and decrease of increments and change of dispersion with decrease of dielectric constant of solvent (water changed to ethanol–water)[1]. It was thought of interest to investigate in more detail the effect of excess counter ions.

The ellipsoid method[2], which permits measurements with solutions with comparatively high electric conductivity, was used for the determination of dielectric constants, which were made at various frequencies in the range 30 Mc./sec. to 30 kc./sec., so that the dispersion curve due to the solute(s) was obtained in each case. From this the dielectric con-

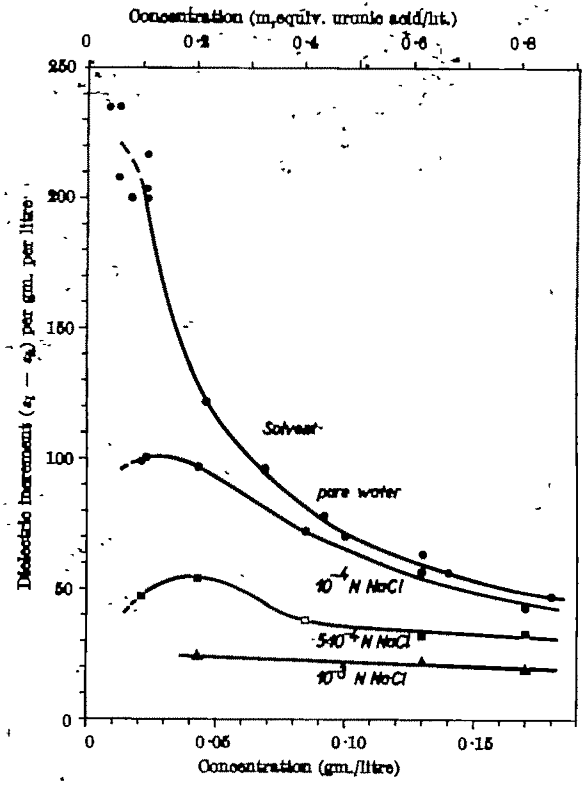

Fig. 1. Dielectric increment per gm. per litre of sodium alginate in water and at various sodium chloride concentrations. pH about 6

stant at high frequencies (ϵ_h) and low frequencies (ϵ_l) relative to the dispersion region was obtained graphically. The difference between ϵ_l and ϵ_h is the increment used for further calculation.

Fresh solutions of sodium alginate (purified by high-speed centrifuging and dialysis, freeze-dried, number average molecular weight approximately 50,000)[1] in pure water were investigated during the time interval 2–8 hr. after dissolution. Solutions in 10^{-4}, 5×10^{-4} and 10^{-3} *N* sodium chloride were prepared by dilution from 0·04 per cent alginate stock solutions in the respective solvents. Stock solutions were stored at approximately + 4° C. and the dilutions were examined during the time interval 1–3 days after preparation of stock solution. Sodium alginate was used in the concentration-range 0·01–0·2 gm./litre.

The results obtained are shown in Fig. 1. The dielectric increment has been given as the reduced quantity, increment per gm. per litre, I_{ϵ}. With most proteins and simple dipolar ions studied[2] the increment in pure aqueous solution is a linear function of concentration and thus I_{ϵ} is a constant. With polyelectrolytes this is not the case, and the considerable increase of I_{ϵ} for alginate in pure water with decreasing concentration is a typical finding. If the increment is assumed here simply to be a reflexion of the net (negative) charge of the polyion, then the qualitative interpretation of the shape of the curve in pure water is a decreased polyion – counter ion association with decreasing concentration of polyions. At very low concentrations, namely, less than 0·02 gm./litre, I_{ϵ} tends towards a constant value (although the errors of measurement are high at the lowest concentrations: approximately ± 20 per cent at 0·01 gm./litre as compared with approximately ± 3 per cent at 0·1 gm./litre). This implies that at concentrations lower than 0·01 gm./litre, the (negative) charge of the polyion approaches its maximum value and thus the interaction between polyions and counter ions approaches complete disassociation. The increment will then be a linear function of concentration.

When the solvent contains small amounts of sodium chloride, the higher the sodium chloride content the lower will be the dielectric increment. In accordance with the above argument, this is due to the electrostatic screening of the excess of counter ions, that is, a decrease of the net charge of the polyions with increasing counter-ion concentration. With 10^{-4} and 5×10^{-4} *N* sodium chloride, the curve shows a maximum, which is displaced towards higher polyion concentration with increasing counter-ion concentration. This effect may be interpreted as being due to the competing actions of increased screening with increased counter-ion concentration, leading to a decrease of the increment, and the tendency towards a higher I_{ϵ} value with decreasing polyion concentration, as stated above. The former effect will prevail at polyion concentrations lower than those of the maximum of the curve. At the maxima the concentration of polyions and counter ions is of about the same order on the basis of equivalents per unit volume.

With the highest sodium chloride concentration studied, 10^{-3} *N*, I_{ϵ} approaches a constant value. Thus polyion – counter ion association occurs at all concentrations and the net charge of the polyion approaches zero. At this concentration of counter ions there is still a residual increment. Unfortunately, it does not seem possible with present methods to make dielectric measurements at higher simple electrolyte concentrations than approximately 10^{-3} *N*.

Towards higher polyion concentrations all the curves show a tendency to extrapolate to a common and constant value of I_{ϵ}. This corresponds to the state just mentioned, due to the prevalence of polyion – counter ion association.

In the region of low concentration studied here, the results are in general agreement with those obtained in other studies of polyelectrolytes[4]. My curves show striking resemblance to curves obtained when plotting reduced viscosity vs. concentration for a number of polyelectrolytes under similar experimental conditions[5]. A similar interpretation to that given here for the dielectric increment has been given for the electroviscous effect.

Thanks are due to Alginate Industries, Ltd., England, for the gift of a sodium alginate sample ("Manucol SS/LH 30591") and to the Karolinska Institutet and the Thérèse and Johan Andersson Foundation for financial support.

FORTHCOMING EVENT

Monday, December 20

Operational Research Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Meeting on "The Accuracy and Function of Time Study".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant, Grade B (with an honours degree in mathematics or engineering, and with suitable teaching experience), in the Department of Mathematics—The Registrar, College of Technology and Commerce, The Newarke, Leicester (December 28).

Principal Scientific Officer (with a first- or second-class honours degree in mechanical or chemical engineering or equivalent qualification, and some postgraduate research experience), at the Mechanical Engineering Research Laboratory, East Kilbride, Glasgow, to lead a research team investigating heat transfer in heat exchange plant—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S.4401/54 (December 29).

Principal Scientific Officer (with a first- or second-class honours degree in engineering or equivalent qualifications) at the Mechanical Engineering Research Laboratory, East Kilbride, near Glasgow, to initiate research into fundamental factors underlying the wear and lubrication of internal combustion engines, using modern techniques (e.g., radioactive tracers)—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S.4405/54 (December 30).

Analytical Chemist (with a degree in chemistry or equivalent qualification, and preferably with experience in analysis of compounded materials) in the Plant Protective Chemistry Section, for work which will consist mainly of analysis of spray materials and residues—The Secretary, East Malling Research Station, near Maidstone, Kent (December 31).

Assistant Experimental Officer (with a pass degree (chemistry or botany), or at least the general certificate of education at advanced level), in the Chemistry Section, to work mainly on the effects of crop residues on the soil—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (December 31).

Chemical Engineer, Senior Scientific Officer grade (with a first- or second-class honours degree in chemical engineering or equivalent, and postgraduate experience in development work, including design of pilot units), at a Ministry of Supply Establishment located in S.W. England, to be concerned with the development of chemical processes involving semi-technical research and design and operation of pilot units—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.806/54A (December 31).

Chemist (with a first- or second-class honours degree or equivalent qualification in chemistry, and preferably with postgraduate experience in physical analytical methods, micro-analysis, chromatography, corrosion of metals or biochemistry) at the Ministry of Supply Tropical Testing Establishment, Port Harcourt, Nigeria, to take charge of a chemical laboratory, and work on chemical and biochemical problems associated with the study of deterioration under tropical conditions of materials and stores of all types—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.816/54A (December 31).

Laboratory Technician in the Department of Chemistry, Potchefstroom University for Christian Higher Education, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, December 31).

Physical Chemist (with at least a good honours degree) for investigation on macromolecular substances of biological origin by physical methods—The Chester Beatty Research Institute, Fulham Road, London, S.W.3, quoting "Physical Chemistry" (December 31).

Physicists and Chemists, to carry out research into glass-making problems—The Secretary, British Glass Industry Research Association, "Elmfield", Northumberland Road, Sheffield 10 (December 31).

Physicist or Electrical Engineer (with a knowledge of electronics, and preferably familiar with electrical instrumentation and measurement techniques), for recording work on rocket motors; and Physicists or Mechanical Engineers for (*a*) experimental and theoretical work on the development of components for liquid and solid propellant rocket motors, and (*b*) for work on heat transfer problems in rocket motor nozzles, at the Royal Aircraft Establishment, Rocket Propulsion Department, Westcott, Bucks—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.346/54A (December 31).

Assistant Experimental Officer (science graduate) to do chemical analysis associated with grassland and other research—The Secretary, The Hannah Dairy Research Institute, Kirkhill, Ayr (January 1).

Engineer (with a good honours degree in mechanical engineering or equivalent professional qualifications, proved research ability and preferably experience in the field of the strength of materials), at the Central Research Establishment, National Coal Board, to lead a group carrying out research on coal cutting—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/891 (January 1).

Research Fellow in Radiation Biology, and a Research Fellow in Biochemistry—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1 (January 1).

Research Worker (with a university degree, preferably in forestry, and with some practical forestry and research experience), to undertake a special study of the problem of planting mining refuse heaps in Scotland—The Secretary, The University, Edinburgh (January 1).

Lecturer (with a good honours degree) in Physics, at the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (January 3).

Mathematicians (with a first- or second-class honours degree in mathematics) at Ministry of Supply Research and Development Establishments in Southern England, for work on a wide range of problems chiefly concerned with aircraft, radio and radar equipment and armaments—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.355/54A (January 7).

Physicist (with a good honours degree in physics, and at least two years experience in radiological physics), at the Combined Military Hospital, Rawalpindi, Pakistan—The Recruitment Officer, Education Division, Office of the High Commissioner for Pakistan, 39 Lowndes Square, London, S.W.1 (January 7).

Chair of Physical Metallurgy—The Registrar, The University, Sheffield (January 8).

Scientific Officer (with a first- or second-class honours degree in an approved scientific subject or other approved equivalent qualification, and preferably with previous industrial experience) in the Department of Industrial and Forensic Science of the Ministry of Commerce—The Secretary, Civil Service Commission, Stormont, Belfast, N. Ireland (January 10).

Principal Scientific Officer (with a first- or second-class honours degree in mathematics, physics or engineering, or equivalent qualifications) at the Mechanical Engineering Research Laboratory, East Kilbride, near Glasgow, to lead a team preparing tables of thermodynamic properties—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S.4402/55 (January 18).

Principal or Senior Scientific Officer (with a first- or second-class honours degree in physics or physical chemistry or equivalent qualification) at the Radio Research Station, Department of Scientific and Industrial Research, Ditton Park, Slough, Bucks, to lead a small, but expanding group investigating the fundamental electrical properties at high frequencies of materials of interest in radio applications and the relation of these properties to their physical and chemical structure—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S.4399/55 (January 20).

Research Assistant (with a first- or good second-class degree in botany or geography, and with ecological or physiographical interests) in Zoology, for work on *Spartina* colonization of coastal areas—The Secretary and Registrar, The University, Southampton (January 31).

Lecturer (graduate in science or agricultural science) in Botany at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, February 1).

I.C.I. Research Fellowships in Biochemistry, Chemistry, Engineering, Pharmacology or Physics—The Secretary, The University, Edinburgh (February 14).

Lecturer in Inorganic and Physical Chemistry—The Secretary, The University, Edinburgh (February 28).

Assistant Conservators (with either a degree in forestry or an honours degree in natural science, with botany as a special subject) of Forests, in the Gold Coast Local Civil Service—Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.61/12/02.

Assistant Lecturers, Grade B, in the Department of Chemistry and Applied Chemistry—The Principal, Royal Technical College, Salford, 5.

Cytologist, for chromosome studies—The Sherardian Professor of Botany, The University, Oxford.

Entomologists (with an honours degree in zoology, and training in entomology) in the Department of Tsetse Control, Gold Coast Local Civil Service, to investigate various aspects of the bionomics and ecology of tsetse flies in relation to man and animals, and to supervise control measures under the direction of the Director of Tsetse Control—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.77/12/01.

Laboratory Assistant (with a general degree in science or agriculture, with main interest in chemistry, or an honours degree in chemistry) in the Department of Agriculture, Kenya, to carry out investigational work on problems of agricultural chemistry related to coffee culture—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.63/7/09.

Laboratory Technician (with experience in the use of routine apparatus, and preferably with biochemical or chemical training) in the Physiology Department—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

Lecturer (graduate in chemistry or biochemistry and experience in the food industry, preferably in the technology of edible oils and fats or of cereals)—The Registrar, National College of Food Technology, Cranwood Street, City Road, London, E.C.1.

Master to teach Biology to Scholarship level—Headmaster, Downside School, Stratton-on-the-Fosse, Bath, Somerset.

Mathematical Physicists (with a first- or second-class honours degree in mathematics or physics, together with some years appropriate postgraduate research experience), for work in one of the following fields: astrophysics, fluid dynamics, nuclear physics or statistics—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 283/WGE/2.

Physicist (with an honours degree, and an interest in classical physics, fluid mechanics and statistical analysis) to work with a small team engaged on a long-term study of the principles of operation of paper-making machines, and, in particular, of fluid flow of pulp suspensions—The Director, British Paper and Board Industry Research Association, St. Winifred's Laboratories, Welcomes Road, Kenley, Surrey.

Research Assistant (female) (preferably B.Sc. (bacteriology)), for duties concerned with research on serology of viruses—The Secretary, Foot-and-Mouth Disease Research Institute, Pirbright, Surrey.

Research Assistant (Ph.D. standard), for work on reaction kinetics at gas-solid interfaces—Dr. Tomkins, Imperial College, London, S.W.7.

RESEARCH ASSISTANTS (with a higher or ordinary national certificate in science, technology or engineering, Inter.B.Sc., or equivalent qualification) IN THE FUEL TECHNOLOGY SECTION of the Physics Department—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "Fuel Technology".

TECHNICIAN (with G.C.E. advanced level in mathematics or physics), for work in the isotope laboratory—The Director, Radiotherapeutic Research Unit, Hammersmith Hospital, Ducane Road, London, W.12.

THE NATURE CONSERVANCY

WHEN attention was directed to the work of the Nature Conservancy in an adjournment debate in the House of Commons on October 22, the two principal points stressed were the importance for the work of the Conservancy of both adequate finance and of public understanding. Those are likewise the two major points emphasized in the report of the Conservancy for the year ended September 30, 1954*, apart from the summary of the revised scientific programme of the Conservancy. During the past year, most of the remaining major gaps in the first stage of building up its organization and working arrangements have been filled; and for England and Wales the initial reconnaissance and listing of sites of special scientific interest have been finished, though the greater part of Scotland remains to be tackled, with the exception of the Central Lowland countries, where most threats to sites of this character arise. The Conservancy's two research stations and its two field stations were manned, fitted out and in almost full operation in time for the spring and summer field-work programme of 1954, while with the removal to the new London headquarters in Belgrave Square the important supporting services, notably the library and those for documentation, maps and photographs, came into fuller operation.

Owing to the long-term nature of the Conservancy's research work, the full results of these developments will not be felt for some years; but meanwhile administrative reorganization has permitted extensive decentralization, considerable progress has been made in identifying recurrent problems and in formulating appropriate procedures and policies to facilitate quick decisions, and the rate of declaration of national nature reserves, though still too slow, has improved. During the year, the number rose from 11 to 12, the acreage increasing from 22,497 to 71,152, chiefly through the 39,689 acres of the Cairngorm Reserve declared in July 1954. The entire programme of proposed nature reserves and the arrangements for dealing with them are at present under critical and detailed review by the Nature Conservancy.

Already in last year's annual report the Conservancy suggested that finance had become the main limiting factor in its activities. We are now told that, owing to financial stringency, works for the safeguarding and maintenance of existing nature reserves in Britain have had to be cut far below a reasonable minimum, and that in the current financial year severe economy will have to be exercised in respect of all the Conservancy's activities to keep within a financial provision which, in the debate on October 22, Mr. J. R. Bevins put at about £200,000. In the year ended March 31, 1954, actual expenditure, according to the present report, was £181,602 against a grant-in-aid of £125,000, and capital expenditure £34,038 against a grant-in-aid of £15,000, the difference being covered by a balance of £24,686 carried over from the previous capital account. For the six months ended September 30, 1954, expenditure was running close to estimate, and the Conservancy emphasizes that this situation affects the transport and supply of equipment and stores for its research stations and restricts well below the desirable level the award of postgraduate studentships and of grants for scientific work. It also embarrasses land management by compelling the Conservancy to postpone the fencing of reserves and long overdue woodland operations.

---

* Report of the Nature Conservancy for the year ended 30th September, 1954. Pp. iv+55+4 plates. (London: H.M. Stationery Office, 1954.) 3s. net.

The Nature Conservancy is emphatic on the seriousness and urgency of the financial situation. The consequences are fairly and clearly stated, and the argument is the more impressive for the moderation and restraint with which it is advanced. There is no attempt to ignore the stringency of the national economic position or the possibility that conditions at present may not allow the present budget of the Conservancy to be increased; equally, the nation is left in no doubt as to the seriousness of the consequences that may then ensue.

Those consequences in two respects are parallel with those which followed the present Government's, and its predecessor's, parsimony towards the National Parks Commission. First, the acquisition of reserves will be so retarded that a number of irreplaceable sites of the greatest national scientific importance will be irretrievably lost. Moreover, the maintenance and bringing into good order of existing reserves will also be crippled, so that deterioration, both scientific and economic, cannot be avoided. Secondly, the advisory and educational work of the Conservancy, which could be of great value to farmers and foresters, sporting interests, schools and universities, will have to be curtailed or postponed indefinitely.

The importance of both the acquisition of reserves and their educational function, which like the financial situation in general was emphasized in the debate in the House of Commons on October 22, can only be fully appreciated against the context of the general situation in Britain in regard to the use of land. With the increase in population and of production, of mobility and of the claims of defence, the pressure on hitherto untouched land, which was already acute during the War, is becoming even greater. Probably few appreciate the extraordinary number of conflicting claims on individual sites, the amount of man-power used by both central and local authorities in examining and deciding on such claims, and the consequences of the Government's sustained refusal to ensure that Departments are not allowed to be the sole judges of their own causes. The Conservancy testifies to the immense amount of helpfulness and fairmindedness encountered among those concerned with the reconciliation of conflicts of interest over the use of land; but the very admission that there is no simple way of reconciling such conflicts enhances the need for clear and widespread public understanding of the purposes and functions both of the National Parks Commission and of the Nature Conservancy.

But there is a further reason why such educational work should be vigorously carried out by the Nature Conservancy, and one of particular interest to the scientific worker. The function of the Nature Conservancy is not primarily that of conservation or preservation. It is a research or experimental organization of the first importance, and its expenditure should be reviewed as part of, and alongside, the national expenditure on scientific research as a whole. Even its educational work has also an important scientific bearing. One consequence of inability of the Conservancy to employ a sufficient proportion of young scientists who have been trained and to provide them with the necessary technical assistance, equipment and transport to the isolated field sites where much of their work has to be done is, as the report notes, loss of the full fruits of the long-term postgraduate training policy already initiated, and under which ten studentships were awarded during the year and thirty-four were currently in force.

Here again the lower number of awards is attributed to financial stringency and to the rising cost per student. It is the more appropriate, accordingly, that the Conservancy should report direct to the Lord President of the Council irrespective of his membership, *ex-officio*, of the Committee of the Privy Council for Agricultural Research and Nature Conservation. The Conservancy has done well also to include in the present report a summary of the revised scientific programme which has resulted from a thorough review of all existing and proposed research projects, with the object of concentrating effort where it promises the best results, having in mind the scarcity of resources. As a direct outcome of this, the report presents a concise picture of the Conservancy's actual and potential contribution to ecological research which is admirably designed to enlist the understanding and support of scientists generally, whether they are themselves engaged in such work or in related fields or not.

The survey work of the Conservancy aims at acquiring knowledge about every site of scientific interest in Great Britain, a good deal more about sites selected as of major importance (including national nature reserves) and a vast amount on a limited number of sites specially adapted for research. For every nature reserve a reserve record is kept, containing large-scale maps, air and ground photographs at different dates, species lists and censuses, ecological surveys, climatic observations, soil and geological data, historical records, accounts of management operations, and, for all woodland reserves, a vegetation survey and a sylvicultural plan. The work of the Conservancy's scientists is concentrated on reserves or other specially selected sites on which survey is complementary to a programme of research. A more extensive survey programme in Scotland, which is mapping the distribution of the remaining native woodland, will provide a clearer picture of the woodland cover of Scotland, most of which was destroyed by felling and burning; and the Conservancy's research on Scottish mountain vegetation seeks to analyse and describe important areas in greater detail than hitherto attempted and to investigate the effects of such factors as sheep-grazing and snow cover on the distribution and composition of the plant communities. In the south of England a survey across Kingley Vale and Old Winchester Hill Nature Reserves and the proposed nature reserve at Lullington Heath is designed to afford valuable information both on the relations of the vegetation to soil, slope and exposure and on the changes, already noticeable at Lullington Heath, which may ensue when rabbit populations have been greatly reduced by myxomatosis.

To facilitate the availability of results so collected, the Conservancy is also studying appropriate systems of documentation, and has assisted the Botanical Society of the British Isles in compiling an atlas of plant distribution. Close touch is maintained with other ecological research proceeding at the universities, in independent institutions or under official organizations, and the possibility of overlapping is kept constantly in mind. Reference was made in the House of Commons debate to the investigations on myxomatosis and the effect of using chemical spraying for the control of weeds in roadside verges and hedgerows, and to the work on the technique of stabilizing shifting coastlines by means of appropriate vegetation which the Conservancy has resumed at Bridgwater Bay. Like the study of the vole plague in the Forestry Commission's plantations in the Carron Valley, Stirlingshire, or that on the ecology of high-level grasslands with special reference to the grazing factor now being initiated on the Moor House Reserve, these investigations represent as yet a comparatively slight proportion of the Conservancy's scientific effort compared with that expended on the study of woodlands.

That study was the earliest line of research to be developed by the Conservancy. Carried on with the co-operation of the Forestry Commission and largely on Forestry Commission land, it has involved detailed study of soil conditions in relation to a wide variety of species of trees. It has provided a sound basis for assessing the biological productivity of different types of woodland, and has opened up, for example, possibilities of comparing reliably the sustained yield capacity of a given site under different types of afforestation and under different types of cultivation or livestock rearing. The scientific investigations have now been extended to the district around Merlewood, as well as Gisburn Forest, Ennerdale, Roudsea Wood and Witherslack Wood, and Thetford Chase. Studies of soil conservation and afforestation have been extended to peat soils in North Wales and to a Cotswold locality on the Great Oolite, while on the Beinn Eighe Reserve experimental research on the restocking and extension of the wood by natural vegetation includes also the collection of data on the possible structure and dynamics of natural pine forest under Scottish conditions and fundamental studies on the autoecology of the pine.

The bearing of this extensive programme on Britain's economy is obvious; but the Conservancy also points out that in dealing with woodlands no hard-and-fast line can be drawn between survey, research and scientific management. Conservation may involve anything between leaving an untouched wilderness alone and carrying out a comprehensive programme of cautious and flexible modifications of the conditions produced by human interference. In all the Conservancy's woodlands, the first step is reconnaissance and primary survey, followed by the drawing up of a scientific basis of management and by more intensive survey and experimental work. Moreover, at Merlewood a distinct but related line of attack aims at describing the soil fauna associations in different types of local woodlands and studying the role of this fauna in the breakdown of litter and in its incorporation into the forest soils.

Perhaps the most impressive feature of the whole report is not so much the economic and scientific importance of the varied work which is already being carried out by the Conservancy, but the extent of the effort that has been possible within the slender resources available to the Conservancy. Even in the present financial stringency, it seems clear that the nation cannot afford to curtail the activities of the Conservancy, or to incur the risks which are involved if the Conservancy is unable to accelerate its acquisition of reserves and to extend its scientific work. But the question as to the proper financial appropriation for the work of the Conservancy should be considered not in isolation but in the context of the national expenditure on scientific and industrial research as a whole. In relation to an expenditure on civil research, estimated by Mr. J. R. Bevins as of the order of £20 million, an expenditure of £200,000 seems small enough, apart from the important returns in forestry and in agriculture alone which it is already yielding.

The point is one to which the attention of the Advisory Council for Scientific Policy might well be directed, and it should not escape that of the Parliamentary and Scientific Committee. There is a further reason for hoping that the debate on October 22 will stimulate that Committee to take up some of the points raised by the present report of the Nature Conservancy. The potential value of its scientific, educational and other activities is as yet understood and accepted only by an informed minority; yet the effectiveness of some of those activities depends largely on co-operation by local authorities and other bodies as well as by private individuals. There is need, as the Conservancy recognizes, not only to demonstrate this value by tangible results, but also to bring it home to wider circles by effective publicity.

Some of this educational work and publicity is being undertaken by the Conservancy itself, but it is limited by the slender financial resources. It needs to be supplemented by much voluntary work, and the present report supplies material which the scientist could easily use to extend the general understanding of the work of the Conservancy and its national importance. Here in particular the Parliamentary and Scientific Committee could render powerful support, and especially by promoting the fuller and clearer understanding by Parliament of the economic and scientific importance of the work of the Conservancy.

RATIONALISM AS A CREED

Human Society in Ethics and Politics

By Bertrand Russell. Pp. 240. (London: George Allen and Unwin, Ltd., 1954.) 15*s.* net.

WE are told on the dust jacket of this book that, as Bertrand Russell fully subscribes to Hume's view that "Reason is and ought only to be the slave of the passions", it is unfair to criticize him, as many have done, on the ground that he over-estimates the part which reason is capable of playing in human affairs. The present book certainly affords evidence on which the first part of this statement can be based; but we are left in doubt after we have read it whether Russell has worked out for himself a new view of the relation between reason and emotion, or whether he is merely a somewhat repentant rationalist undergoing an attack of second thoughts.

The starting-point of his ethical argument is the assumption that it "differs from scientific argument in being addressed to the emotions" and that the basis of ethics is "emotion and feeling". But this is the last concession that Russell makes to his critics, for he seems to be unable to explain how it is that man is guided by his feelings to distinguish the good from the bad, and assume an obligation to do right rather than wrong. One might suppose from what he says in his more cynical or depressed moments that man's instincts lead him to a course of action in the opposite direction. "There is no limit", he says, "to the horrors that can be inflicted by a combination of scientific intelligence with the malevolence of Satan. . . . Human imagination long ago pictured Hell, but it is only through recent skill that men have been able to give reality to what they imagined. . . ."

It is true that Bertrand Russell concludes that "the bright vault of Heaven" and the "dark pit of Hell" are equally "natural" to the human mind. But he has little to say on the question why it may be hoped that man will seek one and avoid the other. Religious instruction is rejected by him as it fosters "dogmatic beliefs", in the decay of which he can see "nothing but good". "What the world needs", he says, "is not dogma, but an attitude of scientific enquiry, combined with a belief that the torture of millions is not desirable, whether inflicted by Stalin or by a Deity imagined in the likeness of the believer".

To find a source for true belief of this kind, Russell is thrown back on reason once more, despite all his protestations that it is "not a cause of action, but a regulator". The only thing he can find to "redeem mankind" is "co-operation", the first step towards which "lies in the hearts of individuals". It is usual to wish oneself well, but "wishing well to oneself", he argues, "is sure to be futile unless it is combined with wishing well to others", and it is therefore evident to him that this should be made the basis of practical politics. The unhappy truth is, however, that arguments of this kind have not appealed to many of the more destructive politicians of our times, and it is this central problem which Russell has left unsolved.

However, he goes on to claim, it will pay us to be good, in the long run. "It is obvious to every person capable of free scientific enquiry that the doctrines of Lysenko are less likely to increase the wheat supply of Russia than those of orthodox geneticists are to increase the supply of the West. I think it is also very doubtful whether nuclear research can long continue to flourish in such an atmosphere as Stalin produced in Russia." Or, as Gibbon put it, the "gradual advance (of barbarians) in the science of war would always be accompanied, as we may learn from the example of Russia, with a proportionate improvement in the arts of peace and civil policy, and they themselves must deserve a place among the polished nations whom they subdue". Thus do the minds of great rationalists think alike.

It is not, however, on grounds of logical inconsistency that Bertrand Russell's work is most open to criticism. The plain fact is that the rationalism on which it rests does not attract the minds of more than a handful of the young men and women in our universities to-day, who are faced with the responsibility of deciding the critical issues of their lives in the years that lie immediately ahead. Rationalism is a dead creed for them, despite current attempts to accept emotion as well as reason as a significant influence in our lives. It has not yet been replaced in the Western world by anything that stands the tests of criticism and experience, and the younger generation of thinkers must be regarded as facing the intimidating task of discovering a new philosophy and a new faith, or rediscovering an old one.

T. S. SIMEY

NUCLEAR SCIENCE IN PHYSICS, CHEMISTRY AND BIOLOGY

Annual Review of Nuclear Science

Edited by James G. Beckerley. Vol. 3, 1953. Pp. x+412. (Stanford, Calif.: Annual Reviews, Inc., in co-operation with the National Research Council of the National Academy of Sciences, 1953.) 7 dollars.

THIS third volume of "Annual Reviews of Nuclear Science" is the first one for which the editors and the editorial committee of the Annual Reviews, Inc., Stanford, California, are fully responsible. Its policy is evident by the wide field of subjects covered, ranging from reactions of π-mesons with nucleons to vertebrate radiobiology, histopathology and carcinogenesis. Of 392 pages, about 190 are devoted to physics, 80 to chemistry and 120 to biological subjects. The laudable aim as expressed by the editors is to give the 'nuclear scientist' a chance to keep up with the whole field provided he knows the 'fundamentals'. But how does the harassed physicist find time and energy to read it all when the flood of information in his own specialized field is getting larger and less manageable every day? In addition, there are more reviews being published by the American Physical Society, the Physical Society (of Great Britain), "Progress in Nuclear Physics", etc.; these are summaries which the physicist can scarcely neglect and which he may even purchase. He falls into the serious danger of having no time to think for the reading. Does he choose the "Annual Reviews of Nuclear Science" series as an additional source of information if he has to pay 7 dollars? It all depends on the quality: one well-balanced, crystal-clear survey written with didactical virtuosity will go far to convince the hesitant buyer to part with the cash. If, however, he comes across a contribution consisting only of a formidable string of succeeding abstracts of papers, he will put his money back into his pocket. It follows that the author has to have plenty of leisure to read the original publications, to digest it all—a notoriously slow process—and then to set down in good English the rectified distillate of his mental exertions, arranged in a manner logical in its sequence and revealing in its sub-sections. An author who does all that and gets it out by the appointed date is an exception.

The present volume does not do badly in some sections. I liked the summary on reactions of π-mesons with nucleons, by E. M. Henley, M. A. Ruderman and J. Steinberger, because the theoretical formalism is lucidly exposed and the experiments chosen for discussion are relevant to our endeavour to understand nuclear forces. Mesons and heavy unstable particles in cosmic rays, by Louis Leprince-Ringuet, is clear and helpful in the maze of 'new events'. A timely and, I feel, important article on extra-nuclear interactions of electrons and gamma-rays comes from D. R. Corson and A. O. Hanson; it is satisfactory to know that all is happy in the interaction of electrons with electromagnetic fields, at least as long as one is satisfied with the degree of accuracy of experiment and theory, admittedly undesirably low in some cases. Neutron optics, by D. J. Hughes, and a good survey by A. Wattenberg on standardization of neutron measurements follow. Photographic emulsions, by Y. Goldschmidt-Clermont, and radiation dosimetry and protection, by L. D. Marinelli, complete the articles on physics, the latter containing a rather good survey and useful graphs for practical purposes. The chemical field is covered by J. L. Magee on radiation chemistry (very clear exposition), chemical effects of nuclear transformations (J. E. Willard), separation techniques used in radiochemistry (P. C. Stevenson and H. G. Hicks) and isotope effects in chemical reactions (P. E. Yankwich). The volume concludes with vertebrate radiobiology—embryology (R. Rugh) and histopathology and carcinogenesis (J. Furth and A. C. Upton); cellular radiobiology (A. H. Sparrow and J. Forro, jun.); and practical aspects of radiation injury (L. H. Hempelmann and J. G. Hoffman).

The production of the volume seems satisfactorily fast: most of the surveys of the literature were concluded during March–July 1953.

E. Bretscher

THE UBIQUITOUS ALDEHYDE

Formaldehyde

By J. Frederic Walker. Second edition. (American Chemical Society Monograph Series.) Pp. xvi+575. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1953.) 96s. net.

THE prodigious expansion of chemical knowledge and technology is well illustrated by the fact that it takes more than five hundred pages to present "the salient facts and theories" of the chemistry of one organic compound. Ten years only have elapsed since the first edition of "Formaldehyde" appeared, but there is every justification for bringing it up to date. During that decade, the production of formaldehyde in the United States has nearly doubled, improved methods of manufacture have been introduced, its uses have multiplied, and its chemical frontiers have been considerably extended. War-time developments fostered a marked expansion in the uses of formaldehyde, particularly noticeable being the increased volume used for chemical syntheses outside the synthetic resin industry, which is still the major consumer.

In the new edition two chapters out of twenty-one are devoted to the uses of formaldehyde, its polymers and hexamethylene tetramine; the rest deal with production, properties and chemical reactions. This allocation will please some, but disappoint others. It is very doubtful whether workers in the plastics field would agree that less than twenty pages are adequate to discuss the important role of formaldehyde in their industry. However, in defence of the author it must be pointed out that the fundamental chemical reactions on which the industry is based are very ably dealt with under the reactions of formaldehyde, and, furthermore, numerous recent reference books covering the industrial and technological aspects are available. The treatment of formaldehyde production in the opening chapter represents a very marked improvement over the somewhat paltry discussion in the original volume. The five chapters dealing with the physico-chemical properties of the monomeric aldehyde, its vapour and solutions, contain a wealth of data which will prove invaluable to chemists and chemical engineers.

A welcome addition is a section on toxic hazards and safe handling. Polymer formation, one of the most characteristic properties of formaldehyde, receives full and authoritative treatment, but it is surprising to find the term trioxymethylene, which the author admits to be an erroneous designation for paraformaldehyde, still being used synonymously on several occasions. The two chapters on the qualitative and quantitative analysis of formaldehyde, its polymers and solutions are extremely good. Although a distinct chemical entity, hexamethylenetetramine may be regarded as a special form of formaldehyde, since it behaves as formaldehyde in many of its reactions and therefore rightly deserves special mention. Its general reactions, including nitration, are reviewed, but unfortunately the reader is referred elsewhere for details of the complex and interesting chemistry associated with the war-time development of the high explosive *RDX*. A valuable addition to the new volume is a chapter on the reactions of formaldehyde with heterocyclic compounds.

The monograph is not claimed to be exhaustive, and it is not surprising, therefore, to find a few minor omissions; for example, there is no reference to the reaction of formaldehyde with chloral. What is surprising, however, is to find a major industrial use of formaldehyde for the synthesis of glycollic acid, ethylene glycol and methoxymethoxyethanol dismissed at the mere mention and with no more than a brief reference to the patent literature for details of the basic reaction with carbon monoxide. Admittedly, this is a fairly recent industrial development, but the omission is all the more remarkable because the author's own company was responsible for it and since an earlier monograph in this series (No. 114, "Glycols", 1952) gives prominence to it.

A critical selection of references is appended to each chapter, and a comprehensive index at the end. The latter is not without minor blemishes—qualitative analysis is listed for quantitative, and there are some minor lapses of nomenclature. The selection of photographs adds little to the value of the book.

Let these remarks not be construed to mean that this book has not fully maintained the very high standard we have come to expect from the American Chemical Society Monograph Series. This new edition, despite its high price, will be generally welcomed and will inspire chemists to probe still further into the almost endless ramifications of the chemistry of this ubiquitous and versatile aldehyde.

J. Idris Jones

The University of Utopia

By Robert M. Hutchins. (Charles R. Walgreen Foundation Lectures.) Pp. ix+103. (Chicago: University of Chicago Press; London: Cambridge University Press, 1953.) 19s. net.

In this brilliant sketch of the imaginary University of Utopia, Dr. Robert M. Hutchins's avowed purpose is not so much to describe the educationa system of Utopia, of which that university forms the apex, as to depict the hazards to education in the United States and the means by which these hazards may be reduced or eliminated. Chief among them are those arising out of industrialization, specialization, philosophical diversity in relation to the formation of a community, and social and political conformity. These are discussed with wit and shrewdness in four successive chapters representing lectures delivered at the University of Chicago in the spring of 1953. He has returned to some of his criticism of the American universities in lectures on the idea of an American university delivered in Great Britain last autumn, but those lectures are likely to encourage his hearers to read this book.

Although the American university is the main target of his criticism and his fourth chapter in particular is as courageous and forthright a defence of academic freedom and responsibility as is to be found in Prof. Commager's recent book, with which it may be fittingly compared, the book abounds in common sense, in aphorisms, in hard thrusts and asides which will delight the British as much as the American reader. His characterization of the custodial system resulting from the infringement of academic independence as 'adolescent-sitting' may no more commend itself in some quarters than did a certain bishop's proposal to a Lambeth Conference to entitle a conference report on education "Childhood by Second-Childhood". The value of the book, however, does not lie in its occasional astringencies but in the clarity with which it lays bare the fundamental issues involved in deciding what are the functions of a university in the world to-day. The important questions are asked, the essential principles are stated and all concerned with the application of these principles in the expansion of university and technological education in Great Britain, or with the wider question of adult education and the defence of freedom, can read these pages with profit as well as pleasure. R. Brightman

Physical Constants of Hydrocarbons

Vol. 5: Paraffins, Olefins, Acetylenes and other Aliphatic Hydrocarbons. (Revised Values.) By Gustav Egloff. (Monograph Series No. 78.) Pp. ix+524. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1953.) 160s. net.

This volume supplements the values for the melting points, boiling points, densities and refractive indices of paraffins, olefines, acetylenes and other aliphatic hydrocarbons which were collected in Vol. 1. Best values for the normal boiling points, densities and refractive indices of many compounds are also given. Corrections to Vol. 1 are listed with cross-references.

The general arrangement of the matter in the present volume is rather wasteful of space and is frequently not clear. For example, under melting points the symbol *a* is used approximately two hundred times and is followed by the sentence "(*a*) This constant was given as a freezing point in the literature"; if it were necessary to make this distinction, it would have been simpler to put the symbol F.p. in the table. Moreover, confusion may arise because the symbol *a* is used in the same section for other purposes; for example, on p. 10 it means "This is a calculated value", while it has other meanings on pp. 228, 262 and 270. Further, since *a* may have different meanings on the same page, it will be appreciated that there is room for improvement in the arrangement.

Some idiosyncrasies have been noted. Thus, while the formula for methane is given as CH_4, that of monodeuteromethane is given as CD. Under the heading of the boiling point of methane at 760 mm. of mercury pressure are to be found 170 entries for boiling points covering the pressure range 43,168–4·24 mm. and fourteen entries for sublimation temperatures. The majority of these boiling points are arranged in descending order of pressure, but there are just enough entries out of order to break the sequence. The data on acetylene are misleading because, although this compound does not exist as a stable liquid at 760 mm. pressure, since the triple point is at 962 mm., yet four values for the boiling point at 760 mm. are listed.

Vol. 1 was published in 1939, and it is a pity that the opportunity was not taken in the present volume to include information on properties which have since been recognized as useful in establishing the identity and purity of hydrocarbon samples, for example, infra-red spectra, Raman spectra and cryoscopic constants. However, the cost of this volume is already so high that perhaps it is as well that the book was not expanded. Nevertheless, it contains much collected data, and there is no doubt that many librarians will be pleased to have this book to add to their set in this series.

E. F. G. Herington

Paper Chromatography

By Dr. Friedrich Cramer. Second revised and enlarged edition. (Translated by Leighton Richards.) Pp. xii+124+4 plates. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1954.) 25s. net.

It is to be regretted that, in presenting this second, revised and enlarged edition of his book, the author has included so much subject-matter within such a limited space. The book, which is divided into two sections, is intended to provide a laboratory manual of paper chromatography. The first section deals sketchily and somewhat inaccurately with the history and theory of paper chromatography and then goes on to give a comprehensive and well-illustrated description of the various practical techniques. The newcomer to chromatography will find this portion of the book very useful.

The second section describes the application of paper chromatography to the separation of various groups of materials. The presentation of this portion of the book is unbalanced in that some applications are described in excessive detail whereas others receive only the briefest mention. A large number of useful tables and four hundred references, however, are included. That part of the book dealing with inorganic separations is so condensed and contains so many errors that it is better ignored. The book contains an annoyingly large number of mistranslations and spelling mistakes. R. A. Wells

MOLECULAR SPECTROSCOPY

THE ramifications of molecular spectroscopy in pure and applied physics and chemistry are now so numerous and technical progress is so rapid that frequent conferences about them are not superfluous. By any standard, the two-day meeting arranged during October 28–29 by the Hydrocarbon Research Group of the Institute of Petroleum was a success. By bringing together academic and industrial workers in Britain, and others from several European countries and the United States, a critical review of current problems was possible, and future trends in technique and theory were considered. The topics discussed ranged from the vacuum ultra-violet to the far infra-red, and although many papers were directed towards hydrocarbon chemistry, there was a balanced inclusion of results on a wider scale. So far as analytical work and structural diagnosis are concerned, it is becoming increasingly important to choose the most appropriate of the various physico-chemical methods. A similar choice may now be made between the various spectroscopic methods themselves, which are so often not alternative but supplementary to each other.

Opening the first session, E. J. Bowen (Oxford) made a critical evaluation of fluorescence measurements for industrial analysis and examination. Promising as this phenomenon might appear for the study of aromatic or heterocyclic compounds, great care is needed in its interpretation. Older data are often misleading, for few compounds fluoresce, and the fluorescence is destroyed or affected by trace compounds or other factors. Purity of a solvent, and the method of excitation and of spectral recording are important, and re-absorption of the fluorescence must be considered. There may be a gain in the analysis of oils by prior chromatography, or by low-temperature measurements in a solvent which congeals to a clear glass. Yet more information is required about such processes as 'resonance transfer' whereby one molecule transfers its energy of excitation to another trace compound and induces a fluorescence which may be entirely misleading.

G. Porter and M. W. Windsor (Cambridge) described results of another kind on the fluorescence and phosphorescence of aromatic hydrocarbons. It is known that, when suitably irradiated, as solids in glassy solvents, these substances show, in addition to the normal fluorescence which appears during illumination, a slower re-emission of radiation; the latter is composite, one part having a wave-length identical to the main fluorescence and a temperature-dependent decay, the other being a slower phosphorescence of longer wave-lengths. This phosphorescence has been interpreted in terms of a metastable triplet electronic state into which the molecules pass after initial excitation. By means of their elegant method of flash photolysis, Porter and Windsor have now obtained absorption spectra due to the transitions between the triplet levels for solutions of the hydrocarbons. Some microseconds after the flash, while enough molecules are still in the lowest triplet state, an absorption spectrum is measured, and by adjustment of the time interval the decay of the triplet level has been studied from the absorption-band intensities. From the remarkable effect of the solvent viscosity on the kinetics of the decay process, the nature of the triplet state has been examined. The results obtained by this novel technique may have an important bearing upon the photochemistry of aromatic hydrocarbons and of dyestuffs.

B. F. Dudenbostel (Standard Oil Development Co.) reviewed the present state of Raman spectroscopy. As a result of the Toronto mercury arc, the magnesium oxide reflector and more sensitive uncooled electron multiplier tubes, photoelectric recording appears to have replaced photography. Samples as small as 1 ml. can be used, but suspended dust or traces of fluorescent materials must be avoided. The main advantage of direct recording lies, of course, in the direct determination of line intensities or of integrated areas under the recorded peaks. No generalization can be made about which analytical problems will be more suited to Raman or infra-red work, but the former may find much use with aromatics, especially, perhaps, in the higher-boiling petroleum fractions and also with certain mixtures of olefins. The development of an intense monochromatic source of somewhat longer wave-length, with an appropriately sensitive detector, might extend this work considerably.

A vacuum grating spectrometer with photoelectric recording to 1700 A. was described by R. A. Burdett, L. W. Taylor and L. C. Jones (Shell Oil Co.). An E.M.I. photomultiplier with a thin (1-mm.) quartz window was used. A number of substituted benzenes, polynuclear aromatic hydrocarbons and sulphur compounds dissolved in heptane have characteristically different spectra which can be used for analysis more effectively than those in the normal ultra-violet, especially if some preliminary chromatography is carried out. It would seem that a grating is preferable to a prism in the far ultra-violet and that a better source may be obtained for the region 2100–1500 A. by excitation of xenon with a microwave discharge.

The second session dealt with infra-red technique. V. Z. Williams (Perkin-Elmer Corporation) discussed critically the instruments now available for research and for industrial analytical control. The choice between different spectrometers is now mainly governed by the nature of the problem under investigation. Single-beam instruments, with interchangeable prisms covering a wide spectral range, and a double-pass system to increase resolving power and also to eliminate false energy, have high photometric accuracy and elasticity as regards use with accessories such as the reflecting microscope or long-path absorption cells. Double-beam spectrometers, on the other hand, produce a direct spectral record and eliminate atmospheric absorption, and for routine qualitative work in organic chemistry these factors are important. Also, differential analysis using the double-beam arrangement shows much promise for analytical work. However, the flexibility of double-beam instruments is more limited and their photometric accuracy may be less. For pilot-plant or process control, continuously operating infra-red analysers are now in use for determining common gases in fairly complex mixtures. Some incorporate a small monochromator, whereas others work by non-dispersive principles. Much attention has been given to their long-term stability under rugged conditions. Their sensitivity can be as high as 0·25 p.p.m. In Dr. Williams's view, "to some extent to-day and more certainly in three years, these instruments will have a potential for the field which will be greater than the ability of the field to utilize".

These spectrometric developments do not necessarily imply an increase in instrumental complexity. In fact, there is a trend towards simplification for much of the work. One leading factor is the replacement of prisms by cheap echelette diffraction gratings, and L. A. Sayce and A. Jackson (National Physical Laboratory) described their recent work on replication from a helical matrix cut to high accuracy using the method of the Merton nut. The chief experimental inconvenience of gratings hitherto has been the need for some fore-prism arrangement to eliminate unwanted spectral orders. This difficulty may be removed by use of filters which cut off radiation at the shorter wave-length end. Important advances have occurred here by the discovery that thin layers of silicon, germanium, lead sulphide, coated silver chloride, and other substances have fairly sharp cut-off wave-lengths. More exciting possibilities are suggested by the *F*-centre filters developed by J. Gaunt and W. G. Burns (Harwell). Pohl first showed that when crystals of alkali halides acquire a stoichiometric excess of alkali metal they become coloured as a result of trapping of electrons at vacant lattice sites. Such colour centres can be formed by photochemical, radiochemical or electrolytic methods, but more satisfactory results appear to be obtained by heating the crystals with alkali metals. The conditions of preparation and subsequent cutting and polishing still need further study, but good filters appropriate to all the usual spectral regions have been produced. Their additional value for eliminating false radiation in prism spectrometers at longer wave-lengths is also important. The use of cæsium iodide as a prism material (extending to 52 μ) was described by E. K. Plyler (U.S. National Bureau of Standards), and it can be used as a thin window (2 mm.) out to 65 μ. Its dispersive characteristics from 25 μ to 35 μ are not quite so good as those of cæsium bromide. In fact, all spectral needs for a prism spectrometer in the range 2–40 μ can perhaps now be met by lithium fluoride, rock salt and cæsium bromide.

The pressed disk technique used by Stimson and by Schiedt, in which solids are suspended in sintered plates of alkali halide crystal, is improving rapidly. It reduces scatter of radiation, gives sharper absorption bands, eliminates the Christiansen effect and avoids absorption by any mulling agent. M. A. Ford, G. R. Wilkinson and W. C. Price (King's College, London) described their work on this subject and indicated factors such as particle size or sintering pressure which lead to satisfactory disk formation. Care is needed because of spurious impurity bands or possible slow chemical reactions of the solids, and, before quantitative intensity work can be regarded as reliable, further tests are required. T. S. Robinson and W. C. Price (King's College, London) also described a method for calculating the absorption spectrum of a solid from its reflexion spectrum. The computation is rather elaborate, but may be useful in those cases where the absorption of thin films is still too high, as with polytetrafluoroethylene. If polarized radiation is employed the reflectance data may also be used to determine the directions of certain bonds in a molecule with respect to the crystal axes.

Several papers dealt with the interpretation of vibrational spectra for analysis, vibrational assignment and structural diagnosis. Hitherto, infra-red analysis has usually been made on the assumption of additivity of optical densities at band peaks, using extinction coefficients defined by Beer's law. This method is in reality semi-empirical, since it assumes the use of infinitely narrow slit-widths which pass monochromatic radiation. The extinction coefficients depend markedly upon the spectrometer slit-widths unless the latter are small compared with the band half-widths, and this factor alone may account for our inability to transfer infra-red data from one instrument to another. Integrated band areas have a more absolute significance, especially if they are suitably corrected for the spectrometer characteristics so as to yield the true band intensities. The band areas can be computed in several ways, but there is still uncertainty about the exact function which reproduces the band envelopes. Quite apart from their use for analysis, however, band intensity data may lead to further refinement in structural group identification, and since the intensity is related to the variation of molecular dipole during vibration, they may also tell us something about the bond polar properties. These several aspects of work on band intensities were discussed by H. W. Thompson (Oxford) and illustrated by a collection of data so far available. The construction of simple automatic devices for the integration of band areas during spectral measurement will not be long delayed. Whether, owing to band overlap or for other reasons, the true intensities will prove more valuable than extinction coefficients determined with higher spectral resolving-power, is at present an open question.

Tables of molecular vibration frequencies of substituted benzenes, which appear to depend only upon the positions of the substituent groups and not upon their nature, have been collected together by R. R. Randle and D. H. Whiffen (Birmingham). While there may still be doubt about some of the assignments to specific normal modes, and some of the rules may fail with other substituents, these correlations will be valuable, especially in hydrocarbon chemistry. Similar data were listed by E. D. Kunst (Royal Dutch Shell, Amsterdam) for deutero-aromatics in the region 12–14 μ. H. Lüther (Technical High School, Brunswick) described spectral measurements designed to elucidate the mechanism of oxidation of hydrocarbon oils, using key bands for detection of hydroxyl, ketonic and other groups.

The comparison of vibrational spectra of molecules in different states of aggregation is now leading to important information. This was fully surveyed by N. Sheppard (Cambridge) with particular reference to measurements at low temperatures. The spectral variations observed, and their interpretation, vary according as the molecule is rigid or flexible and also depend upon the coupling of vibrations in the solid lattice. Conclusions have been drawn about the relative stability of rotational isomers and about the assignment of vibration frequencies of long-chain hydrocarbons. In solid nitric acid hydrate there is spectroscopic evidence for the occurrence of the

OH_3^+ ion. The sharpening of bands at low temperatures and other features may find application in certain analytical work; but this may involve some experimental problems, and the formation on solidification of an amorphous glass rather than a crystalline mass may be vital.

Attempts to study reaction intermediates and radicals through their spectra have not, so far, been entirely successful. D. F. Hornig (Brown University) described a new approach in which shock waves have been used to excite molecular species to a 'temperature' equivalent to that of reactions or combustion processes. The time required to induce this excitation—some microseconds—may be much less than the reaction times, and it is hoped, therefore, from spectral emission or absorption to study the subsequent kinetic behaviour of the species. Very fast photographic and photoelectric methods have been used to record spectra of certain radicals produced by passing shock waves into substances such as cyanogen halides or methyl halides, and the progress of such work should be interesting. The identification of radicals in flames by resolution of their vibrational–rotational emission bands was achieved recently by Plyler, Benedict and Silverman. G. R. Wilkinson, M. A. Ford and W. C. Price (King's College, London) have now made similar measurements on emission bands in the region 1–5·5 μ of simple molecules and radicals excited by a radio-frequency discharge in hydrogen halides, methane, water vapour and other gases. This method has definite advantages over absorption measurements in that band sequences are more fully developed, and both the rotational and vibrational constants can be measured conveniently. The results of recent absorption studies on a number of hydrocarbons using very high resolving-power were also outlined by H. W. Thompson. From all these data, more precise values are being obtained, not only for the main molecular rotational constants but also for the centrifugal stretching-coefficients and anharmonic vibration factors.

Among all the above fairly conventional themes, a new note was struck at the meeting—the study of nuclear magnetic resonance—and R. E. Richards (Oxford) illustrated its value by many examples of practical importance. The spin of a charged nucleus gives rise to a magnetic effect, and the associated magnetic vector can be oriented in different ways in an applied magnetic field. These orientations correspond to different quantized energy-levels, between which transitions can take place. For fields of 10 kilogauss the absorption frequency lies in the radio region, 'resonance' occurring between the two levels and different nuclei absorbing at characteristically different frequencies. When interaction occurs between the nuclei and their surroundings—to be exact between their respective magnetic effects—the absorption lines broaden in ways which depend upon the internuclear distances and other structural features. Thus groups such as CH_3, CH_2 or OH can be characterized. Information of the most varied kind, both qualitative and quantitative, can now be obtained, and it is certain that much will result from this new highly sensitive method.

It is clear that there is intense activity in this field. The difficult task of setting up a punched-card system for reference spectra was also discussed, and it is hoped that the committee set up several years ago in Britain to consider this matter may shortly be able to institute a scheme.

H. W. Thompson

FULMER RESEARCH INSTITUTE, STOKE POGES

OPEN DAY

An informal visit was made to the Fulmer Research Institute on November 2 by H.R.H. the Duke of Edinburgh on the occasion of an open day held to mark the opening of the new Mechanical Testing Laboratory of the Institute. After a tour of the laboratories lasting for an hour and a half, during which he pulled the first test-piece in the new 50-ton tensile-testing machine of the Laboratory, the Duke had luncheon at the Institute together with some three hundred guests representing industry and research. In his speech he said that he had always been convinced that the research business was a good investment and that he was interested to have practical proof in an establishment which, without outside support, does indeed make a profit entirely on research. After luncheon the laboratories were open to the other guests, and the scientific exhibits showed in detail some of the work of the Institute during its first seven years of existence.

Following the invention of the catalytic distillation process for refining of aluminium, Dr. P. Gross and his colleagues demonstrated similar studies applied to the extraction of titanium from impure titanium-bearing materials. Laboratory exhibits showed that titanium can be removed from an impure titanium-bearing alloy by reaction with a high-valency halide to form a halide of lower valency in the vapour phase. Disproportionation of the lower-valency halide then gives a deposit of pure metallic titanium with re-formation of the higher-valency halide. In connexion with the work on the purification of both aluminium and titanium, an intensive study is in progress of the reactions which may be involved in these processes, and an important feature of the work is the determination of the heats of formation of metallic halides. The apparatus, which includes dry boxes for handling deliquescent halides and a calorimeter made in the laboratory workshops, was on view. The heat of formation of aluminium fluoride has recently been re-determined by Dr. Gross, and a new value, differing appreciably from that previously accepted, has been established and the results published. The heat of formation of titanium tetrachloride has also recently been determined, but the results obtained are at present confidential to the sponsor. Further work is in hand on the heats of formation of other halides. A recent step forward in Dr. A. H. Sully's work on chromium and its alloys has been the preparation of a ductile form of chromium. Flakes of electrodeposited chromium which are capable of being bent were on view.

In the Physics Section apparatus was set up for studying by X-ray diffraction the structure of liquid metals. This involved the use of Geiger counters in plotting the variation in intensity of X-ray diffraction from a liquid metal surface. Apparatus for measuring the vapour pressure of reactive metals such as uranium was also in operation. Many novel types of camera and a curved quartz crystal monochromator were included in the apparatus for studying the progress of precipitation hardening and the ensuing structural changes. There was an extensive exhibit of the results of such an investigation on the ageing of aluminium copper alloys.

Dr. H. K. Hardy's studies on the thermodynamics of alloy systems and the mechanism of precipitation hardening were also demonstrated, together with the results of recent research on aluminium bronzes and on the aluminium–copper–cadmium alloys. In the Corrosion Laboratory one exhibit indicated the marked influence of directionality of structure on the corrosion and stress-corrosion behaviour of high-strength aluminium alloys. This was correlated with work on the properties of material at the flash line in aluminium alloy forgings where a very high degree of directionality has been observed.

New methods of chemical and spectrographic analysis were demonstrated in the Chemical and Spectrographic Sections. These included a combined chemical and spectrographic method for the estimation of tantalum and niobium in certain soils. Apparatus recently acquired in the experimental foundry includes a vacuum or argon melting furnace in which reactive metals such as uranium and titanium can be arc-melted on to a water-cooled copper hearth. In common with a great deal of other apparatus, this has been constructed in the laboratory workshops. Facilities for metal working included a 60-ton press for powder metallurgical and similar work, a new laboratory rolling mill, a 1-cwt. forging hammer and a small laboratory extrusion press. In connexion with an investigation on the properties of semi-conductors, a technique for melting and casting rods of pure silicon for subsequent purification by zone melting was demonstrated. An exhibit showed work in progress on the development of heat-resisting coatings, and the high-oxidation resistance of steel containing relatively small quantities of silicon and aluminium (3 per cent and 1 per cent, respectively) was demonstrated. Apparatus for the study on a pilot-plant scale of the process for catalytic distillation of aluminium was on view, together with a wide variety of furnaces for heat treatment, including those with facilities for rapid water quenching from vacuum or special atmospheres.

The new Mechanical Testing Laboratory contains a 50-ton Denison tensile compression machine and a thermostatically controlled creep-testing laboratory with seven Denison tensile creep-testing machines of conventional design and four compression-type creep machines. Machines for testing the creep of strip specimens were also in operation in the creep laboratory. Fatigue tests at both room and elevated temperature were in progress, and these included reverse bend tests on sheet specimens, rotating cantilever tests and reversed tension (Haigh) fatigue testing. An interesting exhibit in this section dealt with methods of testing and improving the resistance of aluminium and its alloys to fretting and blackening by abrasion. Work in collaboration with the Department of Colloid Chemistry at the University of Cambridge under the direction of Dr. J. H. Schulman has shown that friction between aluminium surfaces can be markedly reduced by the application of substances forming so-called 'penetrated' monomolecular layers.

The activities of the Institute were described in a booklet which shows that, since 1952, thirty-eight papers from the Institute have been published, or are about to be published, by scientific societies. In the library of the Institute it was shown that, while the research reports of the Institute are confidential to sponsors, a large number of reprints of published papers are available, and a particular feature was the large number of translations, which include many scientific papers translated from the original Russian.

STRUCTURE OF VITAMIN B_{12}

A Crystalline Nucleotide-free Degradation Product of Vitamin B_{12}

IN an earlier paper[1] we have described a detailed study of the course of hydrolysis of vitamin B_{12} under both acid and alkaline conditions. It was found that under rigorous experimental conditions there were produced 1-amino-2-propanol, ammonia, 5 : 6-dimethylbenziminazole-1-α-D-ribofuranoside-2′-(or 3′)-phosphate and a deep red cobalt-containing gum which behaved as a mixture of tetra-, penta- and hexa-basic acids in the case of alkaline hydrolysis, or as a mixture of tetra-, penta-, hexa- and hepta-basic acids in the case of acid hydrolysis. The mixture of cobalt-containing acids obtained from the alkaline hydrolysis of the vitamin has now been subjected to further fractionation in order to provide material for chemical degradation and physical examination.

Vitamin B_{12} was hydrolysed with 30 per cent sodium hydroxide at 150° for 1 hr., and the tetra-, penta- and hexa-basic carboxylic acids as well as the accompanying free nucleotide were separated by electrophoresis on Whatman seed-testing paper[1,2]. Of the three coloured fractions, that corresponding to the hexabasic acid was present in the largest amount. It was converted into its ammonium salt, absorbed on a column of 'Dowex 1 *X* 2' resin (2 per cent cross-linking) and eluted with 0·6 *M* ammonium acetate solution. Several minor fractions were eluted first and were followed by the major band, which was collected separately. It was worked up in the usual way by acidification with hydrochloric acid, extraction into phenol, removal of the inorganic salts from the phenol extract by washing with dilute hydrochloric acid and then water, dilution of the phenol with ether and re-extraction of the red acid into water. After evaporation of the water, the gummy residue was dissolved in aqueous acetone and diluted with ether and kept for several weeks, when a small quantity of red prisms was obtained. This crystalline product was submitted to Dr. D. C. Hodgkin and the elegant crystallographic examination described in the following communication was carried out on one selected crystal. Further dilution of the mother liquors with ether gave fine red needles which were soluble in aqueous acetone but insoluble in either water or acetone alone. Recrystallization was wasteful but could be effected by adding ether cautiously to the aqueous acetone solution, when crystalline material was obtained from the cloudy solution after removal of some amorphous material precipitated initially. (Found on material dried to constant weight at 54°/0·05 mm. : C, 52·8 ; H, 6·3 ; N, 7·85. $C_{47}H_{66}O_{16}N_6CoCl$ requires C, 53·0 ; H, 6·25 ; N, 7·9 per cent.) An aqueous solution of the product in dilute nitric acid contained chloride ions.

The ultra-violet absorption spectrum (Figs. 1 and 2) shows a strong resemblance to that of vitamin B_{12} ; differences in the 280 mμ region are due to the absence of the 5 : 6-dimethylbenziminazole nucleotide in the hydrolysis product. In the presence of excess cyanide a bathochromic shift of the spectrum is obtained similar to that observed with vitamin B_{12} and indicates that the chromophore of the hexabasic acid is closely related to that of the parent vitamin. The infra-red spectrum, determined on a 'Nujol' mull, showed maxima at 4·67, 4·73 (weak), 5·77, 5·85, 6·01, 6·15, 6·30, 6·64, 7·74, 8·64, 8·98, 9·15,

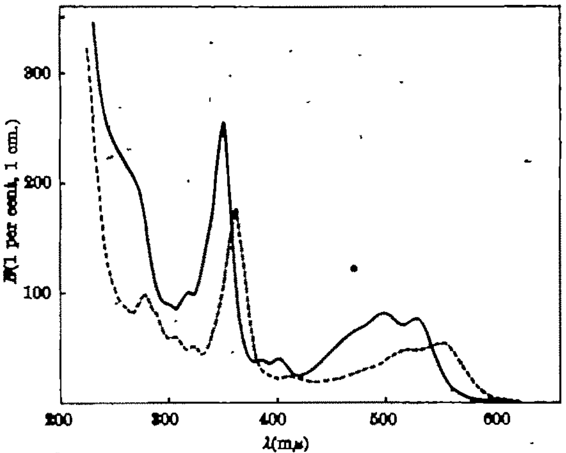

Fig 1. Ultra-violet absorption spectra of vitamin B_{12} (air-dried, - - - - - -) and the hexacarboxylic acid degradation product (———) in water

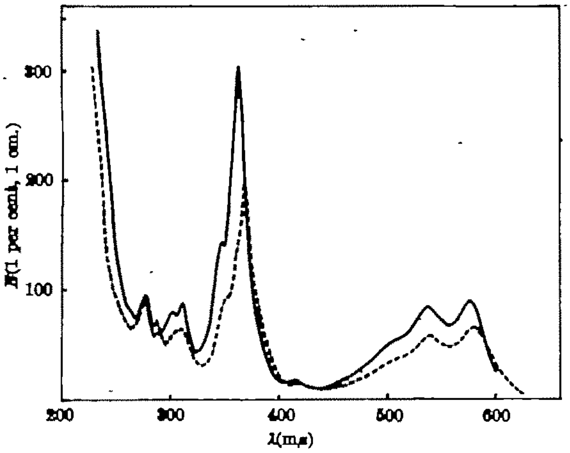

Fig. 2. Ultra-violet absorption spectra of vitamin B_{12} (air-dried, - - - -) and the hexacarboxylic acid degradation product (———) in 0·1 *M* potassium cyanide

9·40, 9·53, 9·85, 10·25 and 12·30 μ. The maximum at 4·67 μ indicates the presence of the cyanide ion, and the absorption in the carbonyl region together with a strong inflexion in the 3–3·8 μ region are consistent with the polycarboxylic nature of the pigment. The virtual absence of strong 'aromatic' bands in the 11·5–14·5 μ region of the spectrum is also noteworthy.

The red needles were unsuitable for X-ray studies, but it is probable that they are a polymorphic modification of the prisms obtained originally, for on one occasion the needles were converted into prisms on keeping in the presence of the mother liquors, and the crystals so obtained were identical (X-ray powder photograph) with those supplied earlier to Dr. Hodgkin.

Later experiments have suggested that the multiplicity of bands obtained by elution of the electrophoretically pure acids from ion-exchange columns with solutions of salts, for example, ammonium acetate, in the absence of excess cyanide, and also the great reluctance of all these compounds to crystallize, is caused mainly by the ease of exchange of anions other than cyanide attached to the central cobalt atom. Work on the changes occurring in the co-ordination state of these acids under various conditions, and further chemical degradations are in progress.

The award of a Beit Memorial Fellowship for Medical Research to one of us (J. R. C.) is gratefully acknowledged.

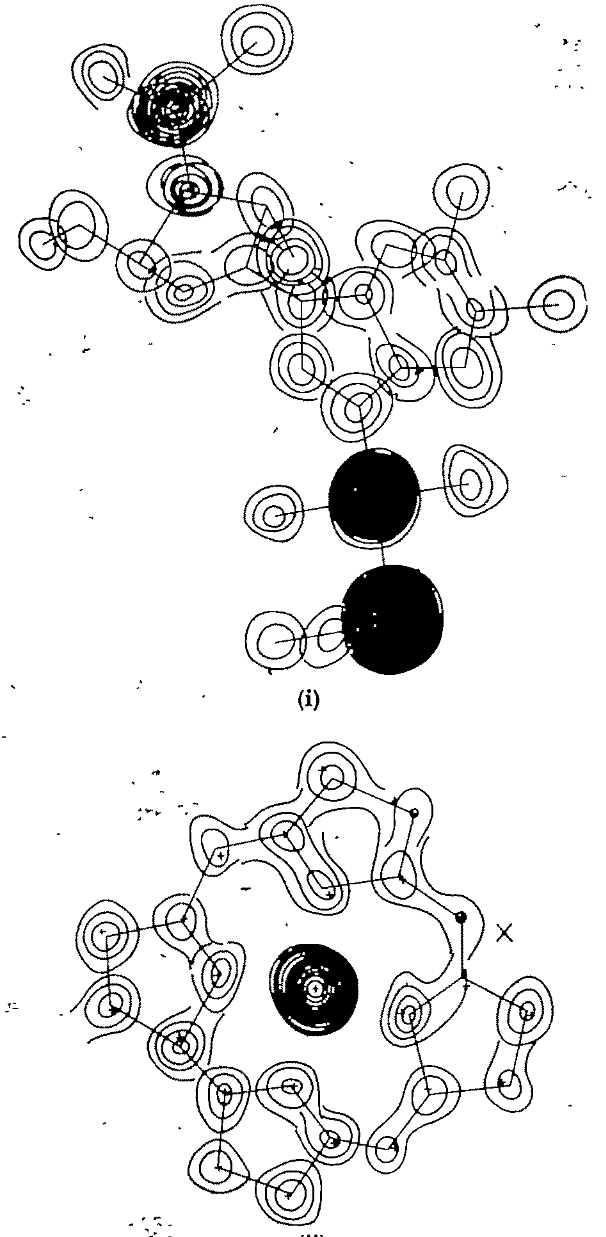
X-ray Crystallographic Evidence on the Structure of Vitamin B_{12}

It is not usual in X-ray analysis to present evidence of part only of a crystal structure. We have, however, reached a point in the investigation of the structure of vitamin B_{12} at which we have obtained strong evidence for the existence of a new type of ring system within the molecule, although we cannot yet describe in detail the nature of the groups attached to it.

Vitamin B_{12} has been shown[1] chemically to contain cobalt, a nucleotide-like group (5 : 6-dimethylbenziminazole 1-α-D-ribofuranoside (2′ or 3′)-phosphate), and a CN group, which together account for $C_{15}H_{18}O_7N_3PCo$ out of a total[2] of approximately $C_{61-64}H_{86-92}O_{14}N_{14}PCo$. There is chemical evidence in addition for the existence of groups which give rise to propanolamine on hydrolysis and to various simple acids on oxidation[3], but a major portion of the molecule is at present of largely unknown character. It is for part of this structure that we now have evidence.

We have obtained complete three-dimensional X-ray data for four crystals: air-dried vitamin B_{12} (two independent sets of data obtained at Oxford and at Princeton), wet vitamin B_{12} (the crystal in its mother liquor), vitamin B_{12}-SeCN (having the CN of B_{12} replaced by SeCN), and, very recently, a red degradation product of vitamin B_{12} from which the nucleotide and propanolamine have been removed. In each of these cases, we have found the positions of the heavy atoms in the crystal by direct Patterson methods, and calculated three-dimensional Fourier series using our observed *F* values and phases based only on the heavy atom positions: cobalt, or cobalt and selenium. The resulting distributions give a crude approximation to the correct electron density series, containing certainly many spurious peaks, but also containing peaks which must correspond to actual atomic positions. We first recognized peaks corresponding to the CN groups in the case of wet and dry vitamin B_{12} and proved our conclusions correct by the substitution of SeCN for CN. We next recognized the general outline of the nucleotide, placed between the cobalt and a second moderately heavy peak—the phosphorus atom—the ribose being linked to the phosphate at the 3-position[4] and one nitrogen atom of the benziminazole nucleus co-ordinated to the cobalt[5]. Between the nucleotide and CN group, and surrounding the cobalt atom, appeared a group of largely planar form, similar in dimensions to a porphyrin nucleus. Attached to this nucleus could be located, though less precisely, various side-chains and possible other ring systems.



(i)

(ii)

Fig. 1. Positions of certain of the atoms in vitamin B_{12}-SeCN derived from the second calculated three-dimensional electron density distribution

(i) The phosphate, ribose, benziminazole, cobalt and selenocyanide groups viewed along the *b*-axis

(ii) The 'planar' group viewed along the *a*-axis

In this figure, and in Fig 2, the contours drawn are those showing the electron density in sections in the three-dimensional distribution, passing at or near each individual atomic position

In the next series of calculations on air-dried vitamin B_{12}, made both in Oxford and Princeton, it was assumed that the planar group had in outline the form expected for a normal porphyrin. But more detailed comparison of all three series for vitamin B_{12} later obtained in Oxford suggested that, in fact, no true porphyrin was present. Three of the five-membered rings appeared separated each by a single atom, but the fourth seemed directly linked to the first. At this point, different refinements of the first electron density series were calculated. In those derived at Princeton, for vitamin B_{12} itself (J. W.), atomic positions corresponding to a normal porphyrin were inserted, together with successively increasing numbers of positions postulated for the rest of the molecule. In that obtained at Oxford, based on vitamin B_{12}-SeCN, the modified porphyrin-like structure was used, together with postulated positions for all the atoms in the unit cell. Comparison of results provides strong support for the modified planar group. The region of the directly linked five-membered rings appears most distinctly in the vitamin B_{12}-SeCN series. This is illustrated in Fig. 1, which shows the appearance of the planar group, projected along the *a*-axis (ii) together with that of the benziminazole–ribose–phosphate system viewed in the direction of the *b*-axis (i). The atomic positions in both these systems are individually resolved and of the height expected, except perhaps in the region marked *X*.

The atomic arrangement found in the planar group is so unexpected that we hesitated to accept this until we examined the degradation product isolated by Cannon, Johnson and Todd and described in the preceding communication. In this crystal the nucleotide is absent and is replaced by chlorine. The relative disposition of the planar groups in the crystal is entirely different from that in vitamin B_{12} itself; but, within the molecule, we can still trace the same essential pattern. The planar group here is considerably inclined to all three axes; a linear group, CN, projects on one side, and on the other, a heavy peak, the chlorine atom, completes the octahedron of peaks surrounding the cobalt. Fig. 2 shows the peaks directly traced from the first three-dimensional series, viewed from the *a*-direction.

There are a few points that we should make. While we are reasonably certain that atoms exist bonded essentially as shown in Figs. 1 (ii) and 2, we have no evidence of their chemical nature; it is natural to suppose that the four directly attached to cobalt are nitrogen, and the rest carbon. Secondly, we have evidence that the system as a whole is not completely planar, but our results are not yet precise enough for us to know at which points the rings are reduced. Again, though we have indications of the existence of side-chains attached to the nucleus, their corresponding electron density peaks are usually

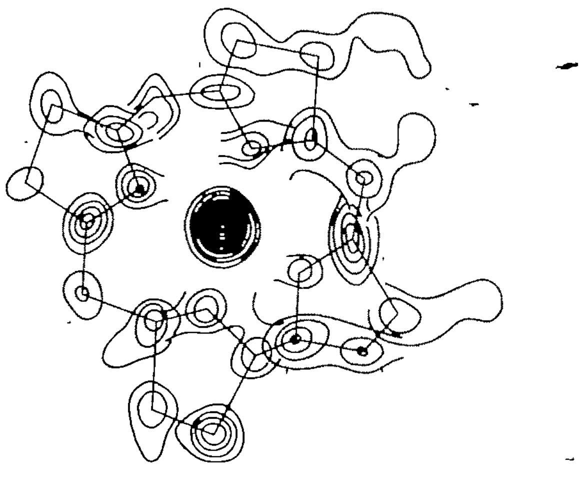


Fig. 2. Positions of the atoms in the 'planar' group as it appears in the first three-dimensional electron density distribution, calculated for the vitamin B_{12} fragment The structure is viewed along the *a*-axis

much less clear than those of the nucleus itself and we differ among ourselves in our deduction of their nature. A great deal more work is clearly necessary to discover in detail these remaining features of the vitamin B_{12} structure, but from our present experience we now have little doubt that a complete solution of the crystal structure by X-ray analysis is possible.

We are very grateful for gifts of material, and for invaluable conversations, to Dr. Lester Smith, of Glaxo Laboratories, Ltd., and to Sir Alexander Todd and his colleagues. One of us (J. W.) would like similarly to acknowledge a gift from the Merck Laboratories. We have had considerable assistance in our calculations from Miss Ruth Cox, Mrs. U. Ledwith, Mrs. M. Mackay and Mrs. I. Robertson, using machines supplied to us by the British Tabulating Machines, Ltd. Other computing has been carried out for us by the Scientific Computing Service, the National Physical Laboratory, and by XRAC, through the kindness of Prof. Pepinsky. Our researches in Oxford have been very generously supported by the Nuffield Foundation and by the Rockefeller Foundation. We also gratefully acknowledge the award of a fellowship by the International Federation of University Women (to C. B.) and of a grant from the Department of Scientific and Industrial Research (J. P.).

OBITUARIES

Dr. C. G. L. Wolf

DR. C. G. L. WOLF, honorary consulting biochemist to the United Cambridge Hospitals, died at his home in Cambridge on November 9 at the age of eighty-two.

Charles George Lewis Wolf was born at Niagara, and graduated M.D., C.M. at McGill University. After a period of study in Cambridge and Würzburg, he joined the teaching staff of McGill University as a demonstrator in chemistry, and in 1899 was appointed head of the Department of Physiological Chemistry in Cornell University Medical College. Dr. Wolf relinquished this appointment in 1911, and for a short period worked in the laboratory of the late Sir Frederick Gowland Hopkins in Cambridge.

During the First World War Dr. Wolf held the rank of captain in the R.A.M.C., and in 1919 he became assistant director of the Institute for the Study of Animal Nutrition in the Department of Agriculture at Cambridge. In 1920 he was appointed to a lectureship in bacteriology in the same Department. He left the Department of Agriculture in 1920, and in 1921 became honorary biochemist to Addenbrooke's Hospital, Cambridge. In the same year he was awarded the degree of Ph.D. for a thesis upon the estimation of lactic acid.

Dr. Wolf's work was characterized by a meticulous regard for accuracy in laboratory technique and by a deep knowledge of his subject acquired by extensive reading in the original literature. He carried out research in widely differing fields. From Cornell University came a detailed study of cystinuria, while in 1917 he published a report to the Medical Research Committee (now Council) on the biochemistry of pathogenic anaerobes. This latter work was initiated at a base hygiene laboratory in Boulogne and continued in the Institute for the Study of Animal Nutrition in Cambridge. In 1921 Dr. Wolf published a paper upon the maintenance of the motility of mammalian spermatozoa during storage, and in 1926, in collaboration with Sir Eric Rideal, he published a study of the Wassermann reaction. About this date Dr. Wolf became interested in various serological methods which had been proposed for the detection of malignant tumours in man, and most of his original work from this time until his retirement lay in this field.

A man of strong personality and forthright in expression of his views, Dr. Wolf numbered many eminent colleagues among his friends. He had an exceptionally keen sense of responsibility towards all who worked under him and was always ready with helpful advice upon their problems. Their subsequent careers were a subject of deep and kindly interest to him, and their appreciation was shown by friendships that lasted until the end of his life.

In 1910 Dr. Wolf married Josephine Rebecca Tallerman, who died in 1949. N. R. LAWRIE

M. Albert Demolon

IN the death of Albert Demolon on October 23, France has lost her most distinguished soil scientist. The death of Mme. Demolon in a road accident in 1950 greatly saddened his last days. He will be affectionately remembered by the many hundreds of soil scientists who had the good fortune to know him as a dynamic personality, physically small but mentally and spiritually a giant.

When only twenty-eight years old, he became director of the Station Agronomique at Laon, and during the next eighteen years he threw himself with great energy into the study of the *limons* soils of northern France. His researches were remarkable for the width of their scope. He was just as competent in microbiology as in physics, and was keenly interested in practical agriculture while seeking for fundamental scientific truth. In the middle of this period he suffered the anguish of seeing his laboratory destroyed by bombardment.

In 1927 he was appointed inspector-general of the stations and laboratories of the French Ministry of Agriculture, a post which he retained until his retirement in 1946. Until 1940 he was also director of the Centre National de Recherches Agronomiques at Versailles. In this position he gathered around him an enthusiastic group of research workers, and was their constant source of inspiration. This period closed with the second destruction of his books and records by enemy action, in 1940, and he sustained further loss when the Centre was bombed in 1944. The fruits of this period are to be found on our shelves in such stimulating books as "Dynamique du sol", "Croissance des végétaux", "Guide pour l'étude expérimentale du sol", "L'évolution scientifique de l'agriculture" and "Génétique des sols".

In all his work we find Demolon rejecting the empirical approach in favour of a sincere attempt to understand the processes at work. He was convinced that this is the surest way to obtain results of practical value in agriculture.

His election to the Paris Academy of Sciences in 1946 marked the beginning of a final period in which he rendered valuable service as adviser to the International Superphosphate Manufacturers' Association, a post which brought him into close contact with many industrial organizations serving agriculture.

R. K. SCHOFIELD

NEWS and VIEWS

Carnegie Institution of Washington : Dr. C. P. Haskins

DR. CARYL P. HASKINS, president and director of research of Haskins Laboratories, New York City, has been elected president of the Carnegie Institution of Washington in succession to Dr. Vannevar Bush, who will retire on January 1, 1956. Dr. Haskins was born in Schenectady, New York, in 1908, and graduated from Yale University in 1930. After four years in the Research Laboratory of the General Electric Company and graduate study at Harvard University, where he received a Ph.D. in 1935, Dr. Haskins established the Haskins Laboratories, a non-profit scientific and educational foundation. This foundation has for eighteen years devoted itself mainly to basic scientific research and research training in selected pioneer fields. With a small staff supported by private funds and grants from various foundations, its original activities were confined mainly to the fields of biochemistry and biophysics; but in recent years it has moved into the field of psychoacoustics, which involves a new approach to some of the fundamental aspects of speech. One of Dr. Haskins's books, "Of Societies and Man" (1950), is particularly interesting in that it sets forth in a novel way significant trends in the formation, growth and duration of societies, drawing information from evolution, palæontology, genetics and biochemistry, and tracing parallels in the social evolution of many different kinds of organisms. Among its conclusions is that over-regimentation and over-specialization destroy in time the self-reliance and flexibility of individuals in the society, and the society then often fails to adjust itself to changes in environment. During the Second World War, Dr. Haskins served with the National Defense Research Committee and the Office of Scientific Research and Development, and since the War has acted as a consultant to the Departments of Defense and State. He has been a research professor in biophysics at Union College, Schenectady, since 1937, and president of the National Photocolor Corporation of New York City since 1938. In 1948 he was awarded the Certificate of Merit and in the same year received from Great Britain the King's Medal for Service in the Cause of Freedom.

Atomic Energy Authority : Appointments

MR. ERIC H. UNDERWOOD has been appointed director of public relations to the United Kingdom Atomic Energy Authority. He will take up his duties early in the New Year. He goes to the Authority from the Central Office of Information, where he was director of the Photographs Division and, earlier, chief editor of overseas magazines. Mr. Underwood, who is forty-one years of age, was educated at Dulwich College. He was a provincial newspaperman until 1940, when he joined the Royal Air Force. At the end of hostilities in Europe he was seconded to the Control Commission for Germany as a squadron-leader press officer until his demobilization at the end of 1945. In January 1946 he was appointed deputy director of public relations at the newly formed Control Office for Germany and Austria, and transferred to the Foreign Office in the following year, going to the Central Office of Information in 1949. Mr. Stanley White, who has been acting as press officer on secondment from the Ministry of Supply, has now been appointed to that post with the Authority. The Authority's Press Office will move from Bedford Chambers to St. Giles Court, St. Giles High Street, London, W.C.2, early in 1955.

Harwell Isotope School

THE Harwell Isotope School, which since it was founded in 1951 has had 329 students from twenty-nine different countries, is now preparing its programme for the forthcoming year. Training is given at this School in the applications of radioactive materials in research and industry and in the techniques of producing, measuring and handling such materials. Countries besides the United Kingdom from which students have already been trained are Australia, South Africa, Argentine, Austria, Belgium, Brazil, Chile, Denmark, Egypt, Finland, France, Germany, Greece, Holland, India, Ireland, Israel, Italy, Lebanon, Norway, Pakistan, Portugal, Spain, Sweden, Switzerland, Turkey, U.S.A. and Yugoslavia. The courses, which last for four weeks, include both lectures and practical work in the laboratory. Students should be graduates of a university. The courses for early 1955 are already fully booked, but there are at present vacancies on Course 27 (April 25–May 20) and Course 28 (June 27–July 22). Further information can be obtained on application to: The Isotope School, A.E.R.E., Harwell, Berks.

International Tin Research Council and Tin Research Institute : Appointments

FOLLOWING the retirement at the end of this year of Mr. John Ireland, Dr. Ernest S. Hedges will become director of the International Tin Research Council and director of the Tin Research Institute. In addition, Dr. W. E. Hoare and Mr. W. R. Lewis have been appointed assistant directors. Dr. Hedges, who was educated at the Universities of Manchester and London, was at one time Darbishire Fellow of the University of Manchester, and later lecturer in chemistry in the University of London. He was appointed to the staff of the Tin Research Institute in 1932 and has been director of research since 1939. He is the author of several books on chemistry and metallurgy, and of more than a hundred research papers. Dr. Hoare is head of the Tinplate Section of the Tin Research Institute, having originally begun his career as a metallurgist with the Talbot Motors Company, and Mr. Lewis is development manager at the Institute.

United States Research Fellowships to British Scientific Workers

Research fellowships tenable in American institutions under a technical assistance programme sponsored by the United States Foreign Operations Administration have been awarded by the National Academy of Sciences, Washington, on the nomination of the Royal Society, London, to five British scientific workers as follows: G. V. Chester, scientific officer, Radar Research Establishment (Ministry of Supply), to work at Yale University, under Prof. J. G. Kirkwood, in the field of statistical mechanics and, in particular, on the molecular theory of fluids; Dr. R. A. Gibbons, research assistant, Department of Biochemistry, Lister Institute of Preventive Medicine, London, to work at the Ohio State University, Columbus, under Prof. M. L. Wolfrom, on problems in connexion with the human blood-group substances; C. G. James, research student in the Department of Physical Chemistry, Cambridge, to work in the University of California, Berkeley, under Prof. Leo Brewer, in the general field of high-temperature thermochemistry and flame equilibria; I. M. Mills, research student in the Department of Chemistry, Oxford, to carry out research in infra-red spectra at the University of Minnesota, under Prof. Bryce Crawford, jun.; Dr. G. L. Squires, a senior research Fellow at the Atomic Energy Research Establishment, Harwell, to work under Dr. Robert Oppenheimer in the Institute for Advanced Study, Princeton, New Jersey, for about three months and then under Drs. John and Leona Marshall in the Institute for Nuclear Studies of the University of Chicago, on experiments in meson physics. This brings to sixteen the number of awards to candidates from the United Kingdom in a programme which, instituted in 1953, is intended to enable some hundred and fifty outstanding young scientific workers from fourteen Western European countries to carry out advanced study for up to two years at American universities and research institutions; part of the time may be spent in American industrial or applied science research laboratories. The grants are worth about 3,300 dollars (approximately £1,180) a year plus travel expenses.

The Nature Conservancy: Annual Report

According to the report of the Nature Conservancy for the year ended September 30, 1954 (see p. 1159 of this issue), by the end of that year the Conservancy had notified under Section 23 of the National Parks and Access to the Countryside Act, 1949, 1,098 sites of special scientific interest in England (coming under sixty-eight planning authorities) and 148 in Wales (coming under thirteen authorities). Progress in Scotland was slower; but by the end of the year seventy-seven sites had been notified to twelve authorities. By the end of the year 528 geological sites out of the 634 proposed for conservation had been inspected, and nearly two hundred photographs of such sites were taken. Only at the beginning of the year did it become possible to trace and write on a large scale to the owners and occupiers of such sites, which vary widely both in size and in the character of their scientific interest. Considerably less than half the owners notified have replied, the great majority promising co-operation; only a small minority has taken exception. In future, where tenants and proprietors can be traced, they will be consulted before further areas are notified to local planning authorities; but it is emphasized that notification is merely a means of informing authorities, owners and occupiers of the fact that they have something of outstanding natural and scientific interest on their land, and the Conservancy has been encouraged by the readiness of many owners to welcome scientists and to see that the scientific interest is preserved.

The report also deals at some length with the new statutory responsibilities of the Conservancy under the Protection of Birds Act, 1954, which came into force on December 1. Under Section 10 of that Act, the Conservancy is responsible for issuing licences in connexion with interference with bird life for scientific or educational purposes for work sponsored by the Conservancy; and it is also one of the bodies empowered to nominate an authorized person for pest control and other specified purposes. Despite certain difficulties, the Nature Conservancy believes that it will be possible to reach agreement on a broad policy in regard to wild-fowl refuges, which will combine the requirements of nature conservation with those of sportsmen, particularly wild-fowlers.

Viruses and the Control of Insect Pests

Outbreaks of insect pests are often brought to an end by outbreaks of infectious disease, and many attempts have been made to control harmful insects by spreading disease among them. In the past the results have been disappointing: the infective organisms have soon lost their virulence. But in recent years some strikingly effective epidemics of disease among insect pests have led to a renewed interest in the method. In 1945 the population of the spruce sawfly in eastern Canada, after reaching alarming proportions, just melted away before a virus disease. This episode served to focus attention on the insect viruses, and that has led in turn to the practical use of introduced virus diseases for insect control, on one hand, and a great increase in our knowledge of these diseases, on the other. In the November number of *Discovery*, Dr. Kenneth M. Smith, of the Agricultural Research Council's Virus Research Unit, at Cambridge, contributes an interesting article which outlines both the fundamental knowledge of insect viruses that has recently been obtained and some of the practical achievements. Thus the alfalfa butterfly in California has been effectively controlled by spraying the crop with stored polyhedra obtained from diseased caterpillars, and the pine sawfly in Canada has been controlled by a virus of polyhedral type procured from Sweden. A very interesting discovery is that some virus diseases are not highly specific, but can attack a number of different species of Lepidoptera; sometimes the virulence of the infection can be increased by mixing two viruses. In general, the persistent nature of the viruses and the fact that they do not affect the natural enemies of the pests make them a promising alternative to insecticides.

Third International Congress of Biochemistry, Brussels

The Third International Congress of Biochemistry will be held in Brussels during August 1–6, 1955, under the presidency of Prof. E. J. Bigwood, rector of the University of Brussels. The scientific programme of the Congress will be made up of symposia, sessions for members' communications and general lectures. There will be, in all, thirty-two symposia, which will cover the following seventeen topics: organic chemistry of substances of biological interest; chemistry and physical chemistry of proteins and polypeptides; chemistry and physical chemistry of nucleoproteins and nucleic acids; enzymology; intermediary metabolism; biological oxidations and oxidative phosphorylations; biochemical regulations; biochemistry of the cell; biochemistry of muscle and the central nervous system; biochemistry of micro-organisms; plant biochemistry and biochemistry of the soil; chemical zoology; nutrition; chemical pathology; chemical pharmacology; clinical chemistry; and industrial biochemistry. The two general lectures, to be given at the opening and closing sessions of the Congress respectively, will be as follows: Prof. Carl Martius (Physiological Chemical Institute of the University of Wurzburg) speaking on "Thyroxin und Oxydative Phosphorylierung", and Prof. Vincent du Vigneaud (Cornell University Medical College, New York) on "The Hormones of the Posterior Pituitary". Those intending to read papers must send in abstracts, not exceeding two hundred words, to the General Secretary of the Congress before April 1. The registration fee for the Congress is 600 Belgian francs (about £4 or 12 dollars) for active participants or 100 francs for associate members. Registration can be made through the American Express Co., Inc. (51 Cantersteen, Brussels, or any of its offices elsewhere), and should be made as soon as possible, in any event not later than May 31. All scientific communications should be addressed to the General Secretary of the Congress at 17 Place Delcour, Liège, from whom further information can be obtained.

Royal Society: Officers for 1955

The following have been elected officers and council of the Royal Society for the ensuing year: *President*, Dr. E. D. Adrian; *Treasurer and Vice-President*, Sir Thomas Merton; *Secretaries and Vice-Presidents*, Sir Edward Salisbury and Sir David Brunt; *Foreign Secretary*, Sir Cyril Hinshelwood; *Other Members of Council*, Prof. W. Baker, Prof. F. W. R. Brambell, Prof. F. Dickens, Sir Alan Drury, Prof. J. H. Gaddum, Prof. L. Howarth, Mr. A. E. Ingham, Prof. W. B. R. King, Prof. W. H. McCrea, Prof. K. Mather, Sir Edward Mellanby, Prof. P. B. Moon, Prof. W. H. Pearsall, Mr. J. A. Ratcliffe, Prof. J. M. Robertson and Dr. C. Sykes.

Mond Nickel Fellowships, 1954

The Mond Nickel Fellowships Committee announces the following awards for 1954: M. Brownlee (Dorman, Long and Co., Ltd., Redcar), to study British, Continental and American hot and cold metal basic open-hearth steel-making with particular reference to furnace design and construction and factors affecting ingot quality; R. D. Butler (Imperial Chemical Industries, Ltd., Liverpool), to study mineral dressing practice in Great Britain, on the Continent and in the United States and Canada, with particular reference to the design, layout and operation of small-scale mills; F. B. Peacock (Dorman, Long and Co., Ltd., Middlesbrough), to study rolling mill operation and maintenance with particular reference to soaking pits, blooming mills and the production of universal beams, structural sections and rails; A. M. Sage (British Iron and Steel Research Association, London), to study the manufacture and fabrication of structural steels in the United Kingdom, Europe, the United States and Canada.

Announcements

We regret to announce the death of Dr. G. F. C. Searle, F.R.S., formerly University lecturer in experimental physics in the University of Cambridge, on December 16, aged ninety.

The title of emeritus professor has been conferred by the University of Sheffield on Prof. I. C. F. Statham, who has recently retired from the chair of mining in the University (see *Nature*, August 7, p. 250).

The Council of the Royal Society has awarded Locke Research Fellowships to the following: M. de Burgh Daly, to work on carotid sinus reflexes and hæmodynamics of the pulmonary circulation, at University College, London; J. C. F. Poole, to work on the effects of fat absorption and blood coagulation and thrombosis, at the Sir William Dunn School of Pathology, Oxford.

Mr. A. D. Knox, lecturer at the London School of Economics and Political Science, has been appointed to the University readership in economics, with special reference to the economics of underdeveloped countries, tenable at the School. The title of reader in economics in the University of London has been conferred on Dr. A. W. H. Phillips in respect of his post at the London School of Economics and Political Science.

On the occasion of the annual general meeting of the Manchester and District Section of the Royal Institute of Chemistry, an exhibition of chemical laboratory apparatus, instruments and techniques will be held in the Manchester College of Technology and will be open to the public on January 5 (2–8 p.m.) and January 6 (10 a.m.–8 p.m.). Special emphasis will be laid this year on distillation and fractionation equipment.

A complete and informative catalogue of recent publications of the Institute of Physics, covering the "Physics in Industry" series, the Institute's two monthly journals and their supplements, the "Monographs for Students" series and numerous reports and pamphlets, together with various books published for the Institute by Edward Arnold (Publishers), Ltd., is now available and can be obtained free from the offices of the Institute, 47 Belgrave Square, London, S.W.1.

Dr. Maurice Cook, joint managing director of the Metals Division, Imperial Chemical Industries, Ltd., has been elected chairman of the British Non-Ferrous Metals Research Association in succession to the Hon. R. M. Preston, who retires from office at the end of this year. In addition to his many contributions to science and technology in industry, Dr. Cook is distinguished for his services to the metallurgical profession. He is a past president of the Institution of Metallurgists and senior vice-president and president-elect of the Institute of Metals, and, among his many activities connected with the Research Association, he has been chairman of the Research Board since 1950.

COMMONWEALTH OCEANOGRAPHIC CONFERENCE

THE idea of a Commonwealth Oceanographic Conference was first put forward at a meeting of the National Oceanographic Council in January 1953. It arose from arguments that the change of emphasis in oceanography, from exploration and survey to research directed towards the precise understanding of the basic physical and biological processes, makes it necessary to devote more effort to theoretical and experimental work. For example, biologists as well as physicists want to know more about the changes in the surface currents and the speeds and variations of the slow but powerful deep-water movements, and it is no longer possible or reasonable to attempt to keep a watch on them all with a network of oceanographic observations like that used in meteorology. The only practical thing is for oceanographers to learn how the water movements are governed by atmospheric pressure, wind and climate so that they can use the meteorological data, supplemented every now and then by their own upper- and lower-water observations.

It would, no doubt, be wrong to suggest that oceanographers took up the subject because they found mathematical and physical sciences too difficult and unattractive; but they have been rather slow in applying the precise techniques of these sciences to marine research. There is more than sufficient interest and profit in the study of the marine animals and plants to keep the marine laboratory busy; but there would be just as much interest and profit in the study of the magnificent interplay between sun, water, air and earth if only we knew rather more about it to begin with. To increase our knowledge the subject must be made attractive to men who do not mind facing up to the difficulties of fluid mechanics. The experienced investigators who have done so much exploration and survey and built up a realistic basic picture can scarcely be expected to turn their hands to the fresh intricacies of such new tasks.

The progress in any science can probably be measured by the interest which the universities take in it; and in oceanography their interest, with one or two notable exceptions, is limited to the biology of the coast and shallow seas. This is understandable, since the problems are interesting and important, and there is much that can be fitted conveniently into university life. As soon as the collection of data becomes too expensive for university departments, and the problems too difficult to afford reasonable expectation that a student can make sufficient progress in two years to sit for a higher degree, the work has to be left to State-aided marine laboratories, and men have to be paid to do it. Even then it is rather difficult to attract first-class men, and a fair number are needed, since nothing less than a team with similar interests is likely to make much headway with a really backward subject.

Most countries of the British Commonwealth engage in oceanography on a considerable scale, dividing their resources between long-term research and the application of existing knowledge to their immediate problems. They all want to increase their activity; but the difficulties of attracting sufficient men with special qualifications and experience, the rising cost of designing and constructing the necessary apparatus and of building, operating and maintaining ocean-going research ships will, sooner or later, make some sharing of the basic studies essential.

The purpose of the Commonwealth Oceanographic Conference held during October 18–22 at the National Institute of Oceanography at Wormley, which was attended by delegates and observers from all Commonwealth countries as well as representatives of authorities interested in marine research in the United Kingdom, was to review the progress of oceanographic research in the Commonwealth, to discuss what measures might be taken to promote its extension, and to further the co-operative use of the available effort and facilities.

The Conference considered the applications of oceanographic research to defence, coastal engineering, shipping, meteorology and fisheries, and concluded that more use could be made of oceanographic research. It was also generally agreed that the investigation of local problems would be furthered by a better understanding of the basic physical and biological processes. It was agreed that the processes most deserving attention are those involved in the interchange of energy between the atmosphere and oceans, response of the sea surface to winds and pressure changes, general circulation of the oceans, distribution of marine organisms and organic production in the oceans. It was recognized that there are other important aspects, but progress in them is more satisfactory, and the immediate need is to direct attention to subjects which require much closer study before our understanding of the underlying principles of oceanography can be sufficient to allow real progress.

The Conference agreed on a co-operative scheme for lending equipment that is expensive, difficult to obtain, and probably only used occasionally, and arranged for the scheme to be started by the National Institute of Oceanography, which had announced its intention to build up a reserve of equipment.

Arrangements for disseminating information similar to those used by the Fuel Research Organization and the Aeronautical Research Council in Commonwealth countries were also agreed. The subject was divided into ten branches, for each of which a chief co-ordinator, located somewhere in the Commonwealth, was proposed: a national representative would pass reports of work done in his country in each of these branches to the appropriate chief co-ordinators, who would summarize and edit information and distribute it annually. It may be doubted whether such a scheme will succeed, but oceanography is a science in which publication, with reasonable confirmation, tends to lag well behind the formation of ideas, and though the tasks of the national representatives and the co-ordinators will be heavy, men with great enthusiasm may produce very useful results. Some benefit will be obtained from the mere fact that the national representative has to judge what contribution his country is making to the systematic development of the subject rather than to knowledge of local conditions.

The need for training more oceanographers was emphasized, and it was decided that the universities should be asked to help by teaching oceanography and doing all they can to encourage postgraduate research in marine physics as well as marine biology.

The Conference endorsed the programme of the National Institute of Oceanography, and considered that its attempt to concentrate on the basic problems, which will benefit the Commonwealth countries by helping them to solve their local problems, should be supported as fully as possible.

The First Lord of the Admiralty, the Right Hon. J. P. L. Thomas, and the Civil Lord, Mr. Simon Wingfield Digby, chairman of the National Oceanographic Council, did much to encourage the work of the Conference. They were hosts at a reception to all members after the first day's session and at a dinner, at which the First Lord presided, given in honour of the Commonwealth representatives, at the close of the meetings.

NEW FORMS OF THERMIONIC CATHODE

A COLLOQUIUM on new forms of thermionic cathode, sponsored by the Institute of Physics and the Physical Society, was held on October 21 at Hirst Hall on the estate at Wembley of the General Electric Company, Ltd., An introductory survey was given by D. A. Wright (G.E.C., Wembley), who pointed out that, for continuous operation for many thousands of hours, none of the established cathodes (Nos. 1, 3 and 9 in Table 1) can be relied upon to give more than 1–2 amp./cm.^{2}. The oxide cathode will give some tens of amp./cm.^{2} in short pulses, but is limited for continuous high current by its sensitiveness to imperfect vacuum, by the dielectric properties of the coating and by evaporation and electrolysis of coating material. Thus, to improve the performance, a cathode with metallic properties is desirable, with a low rate of loss of emissive material. The lowest-temperature emitter obtainable without a dielectric coating appears to be that which maintains a monatomic layer of barium on a metal surface, possibly with some oxygen present. The work function of such a cathode is 1·6–2·0 eV., so that it must be operated at 950° C. or more. At these temperatures, surface barium is rapidly lost by evaporation, and must be replaced from a reservoir in the cathode. The next four papers at the colloquium described cathodes of this type.

Dr. A. Venema (Philips, Eindhoven) described the three forms of Philips dispenser cathode. In the original *L* cathode (No. 5 in Table 1) the reservoir is of barium–strontium carbonate, which decomposes to oxide during pumping and is placed beneath a plug of porous tungsten. The work of Rittner has clarified the mechanism of these cathodes, indicating that barium is formed following reduction of the oxide by the tungsten, and diffuses through the pores as vapour by Knudsen flow. A complete covering of barium on tungsten is maintained by diffusion over the outer surface of the tungsten particles. The life, as shown in the table, exceeds eight thousand hours at a brightness temperature of 950° C., at which the saturated emission is 1·3 amp./cm.^{2}. The life is determined by evaporation, and decreases by a factor of 2½ per 50 deg. C. rise of temperature. The impregnated cathode has similar properties, and is formed by heating a porous tungsten plug in contact with barium aluminate at 1,750° C. in vacuum. The aluminate penetrates the pores, and in operation is reduced by the tungsten. A third type of cathode is being developed, in which tungsten powder and barium aluminate are mixed in powder form, pressed and sintered, again at 1,700–1,800° C.

In discussing the chemical reactions which can be utilized to supply barium to a tungsten surface, Dr. H. Huber (C.S.F., Paris) said that the compounds barium aluminate, silicate, titanate, thorate and tungstate have been considered. The work of Eisenstein, John and Affleck has shown what reducing agents are appropriate for each compound, and Dr. Huber described the results of his study of the emission of cathodes formed by mixing the powdered oxide, tungsten and a suitable reducing agent, pressing and heating at 1,300° C. The preferred cathode is '103' (No. 6 in Table 1), containing five molecular parts of barium tungstate (Ba_3WO_6), fifteen molecular parts of aluminium powder and eighty of tungsten powder, though similar results are obtained if the aluminium is replaced by tungsten carbide, and molybdenum can replace the tungsten powder. Presintering at 1,500° C. is found to be necessary to give long life.

It is not possible to form a cathode by mixing barium/strontium carbonate with tungsten, as there is a reaction which prevents subsequent reduction of the oxide to free barium. The carbonate can, however, be mixed with a more inert metal containing a little reducing agent. Dr. J. M. Dodds (Metropolitan-

Table 1

Type	Operating temperature	Radiated power (watts/cm.^{2})	Maximum usable d.c. emission (amp./cm.^{2})	Life† (hr.)	Work function (eV.)	Richardson *A* value
(1) Tungsten	2,600° K.	80	0·5	10,000	4·5	60
(2) Tantalum	2,400° K.	55	0·5	10,000	4·1	37
(3) Thoriated tungsten	2,000° K.	25	1–3	5,000	2·6	3
(4) Lanthanum boride	1,680° K.	40	1	> 250	2·6	25
(5) Philips dispenser (barium–tungsten)	950° C.B.‡	4*	1·3	8,000	2·1	100
(6) Huber 103 (barium–tungsten)	1,050° C.B. 1,200° C.B.	6* 8*	1·0 4–5	4,000 ~ 400	1·72	3
(7) Dodds (barium–nickel)	950° C.B.	3·3*	6		Not yet measured	
(8) Beck (barium–nickel)	1,340° K. 1,270° K.	3·7* 3·0*	3 1·5	3,000 9,000	1·8	20
(9) Oxide cathode	1,100° K. 1,200° K.	2·8 4·2	0·5 1·0	~ 3,000 < 1,000	1·2	~ 1

* These figures assume thermal emissivities for Nos. 5 and 6 as for tungsten wire (that is, 0·25) and for Nos. 6 and 7 as for nickel sheet (that is, 0·2). In practice they are likely to be higher.

† The figures quoted for life are rough indications only, in all cases.

‡ Temperatures in ° K. are true temperatures. Temperatures in ° C.B. are pyrometer brightness temperatures.

Vickers) and A. H. Beck (Standard Telecommunications Laboratories, Ltd.) described cathodes of this type, formed by mixing 30–40 parts by weight of carbonate with 70–60 parts of nickel powder, pressing and sintering. Dr. Dodds adds as reducing agent 0·1 per cent silicon, and presses at 10 tons/in.^{2}. Mr. Beck uses 1 per cent zirconium hydride as reducing agent, and presses at 80 tons/in.^{2}. His study of the work function has indicated that the activated cathode is nickel with 70 per cent of the surface covered with barium. The temperature coefficient of the work function is $1\cdot4 \times 10^{-4}$ eV./deg. C.

C. P. Lea-Wilson (Services Electronics Research Laboratory, Harlow) described a high-temperature magnetron cathode which emits from thorium-on-tungsten. This again is formed by pressing and sintering, but employs either thorium oxide or thorium metal (about 2 per cent) mixed with tungsten carbide and tungsten. With thoria, gas is liberated over a long period of operation, and about 10 per cent of carbide is necessary to obtain emission. The thorium gives rapid outgassing and activation, and is to be preferred. In the discussion, Mr. Lea-Wilson said that the carbide is desirable even when thorium is used, possibly because it minimizes surface oxidation. There is no information as to whether thorium carbide is formed. The cathode gives a pulsed emission of 20 amp./cm.^{2} at about 1,700° C., and a number of valves have been operated satisfactorily for more than a thousand hours.

Another high-temperature cathode using lanthanum boride as the emitter was described by B. N. Watts (British Thomson-Houston Co., Ltd., Rugby). This is formed by reaction of metal and boron in hydrogen at 1,400° C., and is either painted and sintered on a tantalum filament, or pressed, sintered, machined and heated indirectly. It is activated at 1,600° C. and gives 1 amp./cm.^{2} at 1,400° C., the d.c. and pulsed emission being equal. No long-life test information is yet available.

Finally, P. O. Hawkins (Services Electronics Research Laboratory, Baldock) described an oxide cathode in which the normal disadvantages are overcome by applying the coating on the inner surface of a hollow box, and extracting the electrons through a small hole. From a hole ⅓ mm. diameter, spaced 2 mm. from the anode, the current is very small below 920° C. At high temperatures the current increases at first rapidly with voltage, and then linearly and less rapidly. It exceeded 50 m.amp. at an anode voltage of 5 kV. at 1,230° C. This current if uniform over the hole would be 60 amp./cm.^{2}; but, in fact, the beam is found to be hollow, and the current for varying hole size varies with the perimeter. The mechanism is not understood.

In discussion, Dr. D. Gabor suggested that Mr. Hawkins's cathode contains a plasma from which electrons emerge with high velocity, and the latter agreed that it does not appear to contain an electron gas at the cathode temperature. Dr. P. N. Daykin asked whether n small holes would multiply the emission, and was told that this is so, giving an n-fold multiplication until the hole spacing becomes of the order of the hole diameter. M. E. Haine said that the beam current density per unit solid angle has a definite limit, so that a quotation of amp./cm.^{2} can be misleading. In reply to a remark by Dr. O. Klemperer, Mr. Hawkins said that low-voltage measurements have not been made. Questioned about secondary emission, Mr. Watts said that the secondary-emission coefficient of lanthanum boride has not been measured. Mr. Beck said that his cathodes have a value 10 per cent higher than that for pure nickel, while Dr. Venema agreed that the value for the L cathode is between 1·0 and 1·5. Dr. Huber discussed with Dr. Venema the reason for the former's failure to obtain good emission from barium-aluminate tungsten mixtures containing no additional reducing agent, and it appeared that the barium content and the sintering temperature are the important factors.

BRITISH WEED CONTROL CONFERENCE, 1954

THE second British Weed Control Conference was held at Harrogate during November 2–4 and was attended by four hundred delegates, including representatives from the British Colonies and most European countries. The Conference was organized on lines similar to those of the first one in 1953; that is, the emphasis was on the technology of weed control rather than on the underlying fundamental principles. The papers were divided into two broad classes, one concerned with general reviews of various aspects and the other with research reports on individual topics. The general papers again fell into two groups: the first related to the problems of commercial application, the efficiency of the available spraying equipment, the rotation of weed-killers, schemes for the approval of commercial products, and the legal aspects of spray damage; the second group contained surveys of modern developments in the use of herbicides and the associated problems of the dispersal of weed seeds and the role of mechanical cultivation.

Dr. W. G. Templeman (Jealott's Hill Research Station) reviewed the present position of herbicides in British agriculture. He pointed out that, although great advances have been made in the control of annual weeds in cereal crops, there still remain some relatively resistant and extremely important weeds, such as *Avena fatua* and *Alopecurus agrestis*, for which there are no adequate methods of control. He also emphasized that, while for many crops herbicidal applications are proving of great practical value, the position is far less satisfactory for root crops and many horticultural crops. In the past, too much stress has been laid on the total eradication of the weeds, and in many instances a better approach would be an endeavour to inhibit growth through the disorganization of the physiological processes. For example, 2,4,6-tribromophenylnitramine causes germinating seedlings to lose their capacity to react to tropic responses; but so far no compound with these characteristics has been discovered which is sufficiently selective.

While agreeing that herbicidal applications are playing an important part in British agricultural systems, Prof. H. G. Sanders (University of Reading) nevertheless felt that there is some danger that effective cultivation is not being fully appreciated. He was of the opinion that the hoe does more than kill the weeds and that its use in many circumstances is of direct benefit to the crop.

The organization of weed control investigations sponsored by the United States Department of

Agriculture was outlined by Dr. C. Warren Shaw (Beltsville, Maryland). Apart from the screening of new compounds and some fundamental and development work at Beltsville, similar investigations are being carried out in all parts of the United States under the general direction of four regional coordinators. All this work in turn is linked with similar projects being undertaken by individual States. Dr. Shaw also outlined some of the modern developments which are taking place, particularly in relation to the value of such new herbicides as 2,3,6-trichlorobenzoic acid for the pre-emergence spraying of maize and sorghum, 2,4,5-trichlorophenoxypropionic acid for the control of woody plants in cotton-growing areas, 2,2-dichloropropionic acid for the eradication of graminaceous species, and the likely value of phenyl-substituted ureas for the control of weeds in sugarcane, pineapples, asparagus and possibly cotton. The other materials referred to included N-(1-naphthyl)phthalamic acid as a selective herbicide in cucurbitaceous crops and 3-amino-1,2,4-triazole, which apart from its merit for defoliating cotton is likely to find a variety of uses as a herbicide.

An interesting new development in selective weed control was described by Prof. R. L. Wain (Wye College). In seeking to unravel the basic physiological actions of substituted phenoxyacetic acids, evidence has been obtained of the β oxidation of ω-phenoxyalkylcarboxylic acids. The alternation of biological activity with an increasing number of carbon atoms in the side-chain is only exhibited by some species. From these observations it is concluded that some species do not contain enzyme systems capable of breaking down the original compound to the parent phenoxyacetic acid. Thus, species which do not contain such enzyme systems will be resistant, while others which do will be susceptible. Pot and small-scale field experiments have confirmed this conclusion, and among the susceptible species are many common weeds, such as *Urtica urens*; *Chenopodium album*, *Sinapis arvensis* and *Cirsium arvense*, while resistant crops embrace red and white clovers, parsnips, celery, flax, maize, etc. A survey of the biological activities of γ-phenoxybutyric acids has also demonstrated that the position and number of methyl and chlorine atom substitutions in the benzene ring alter the properties of the molecule, which in turn alter the selective action between species. It is therefore evident that, with the introduction of compounds with odd numbers of carbon atoms in the side-chain, the value of substituted phenoxyacetic acids as selective herbicides will be extended to new crops.

Sir Edward Salisbury (Royal Botanic Garden, Kew) gave an account of the main factors relating to the persistence of weed seeds under British conditions and the principles of dispersal. Examples of the introduction and rate of spread of foreign species, such as *Cardaria draba*, were described. Once the initial introduction has taken place, the spread of the species is dependent upon a number of factors. For example, *Veronica persica*, which seeds very freely, has spread all over the country, whereas *Veronica filiformis*, which seeds but rarely because it is self-incompatible, is still highly localized in its distribution but may extend its area in the locality through vegetative propagation. In discussing the various agencies which lead to weed dispersal, it was pointed out that for birds the interval between ingestion and evacuation varies between thirty minutes and three hours or more, according to the species; thus, the rate of spread is greater where the seeds are readily taken by the larger birds, such as pigeons. Other aspects of seed dispersal by machinery and the laws governing injurious weed seeds and noxious weeds were discussed respectively by F. Coleman (Cirencester) and J. A. McMillan (National Agricultural Advisory Service).

The forty-six research reports presented at the Conference were considered in a number of groups, of which the most important related to weed control in horticulture, grassland, legumes, cereals, row crops and flax, while other aspects considered were the eradication of perennial grasses, the techniques of application both in greenhouse experiments and field trials, and the eradication of woody species under temperate and tropical conditions.

Apart from the selective control of weeds in peas and carrots, in other horticultural crops little progress has been made in the development of compounds which are selective when applied as a post-emergence spray, and most of the contributions bearing on horticulture reviewed the merits and defects of well-established practices. H. A. Roberts (National Vegetable Research Station) discussed the problems connected with the use of pre-emergence techniques and thought that, for contact pre-emergence applications, oil formulations containing pentachlorophenol are of considerable promise. For the control of dicotyledonous annual weeds in peas, dinitrosecbutylphenol is still the most widely used compound, both in Great Britain and on the Continent of Europe, although H. I. Petersen (Denmark) stated that good results have been achieved by using a mixture of dinitrosecbutylphenol and sodium 2-methyl-4-chlorophenoxyacetate. The potential value of *iso*propylphenylcarbamate and its 3-chloro-derivative for the selective elimination of wild oats (*Avena* spp.) and other weeds in peas was also discussed. The best degree of control has been obtained by incorporating the herbicides in the soil before sowing the crop, but no final conclusions can yet be reached as to the direct action of these materials on peas.

The papers on the elimination of perennial weeds from grassland illustrated the complexity of the problem, and the value of the ecological approach in relation to the use of herbicides was emphasized by M. Norman (Grassland Research Station) and A. D. Q. Agnew (Bangor). Turning to other agricultural crops, I. S. Frederiksen (Denmark) and K. Fröier and H. Zienkiewicz (Sweden) advocated the use of mixtures of sodium dinitro*ortho*cresylate and sodium methylchlorophenoxyacetate in fibre flax, while W. Q. Connold and E. I. Prytherch (National Agricultural Advisory Service) commented on the value of sulphuric acid for the control of annual weeds in *Brassica* crops.

Of the papers dealing with weed control in cereals, there was much interest in the contribution of Dr. P. Riepma (Holland), who described the results obtained when weed-free crops of autumn-sown wheat and rye were sprayed with dinitro*ortho*cresol at various times during the winter period. In many instances, appreciable gains in yield were recorded, more particularly in rye; and the maximum gains occurred when spraying took place at the four- to five-leaf stage of development. Dr. Riepma was of the opinion that these increases could not be explained in terms of the nitrogen contained in the herbicide, since the response was independent of the level of available nitrogen supply.

S. Andersen (Denmark) and Prof. B. Rademacher (Germany) gave accounts of experiments which sought to correlate weather conditions with the effects of substituted phenoxyacetic acids on cereals. J. D. Fryer and J. G. Elliott (Oxford) and T. C. Breese (Plant Protection, Ltd.) were in general agreement that, while wheat and barley cannot safely be sprayed until the plants reach the five-leaf stage, the optimum time to spray oats with 2-methyl-4-chlorophenoxyacetic acid is in the one- to four-leaf stage. For perennial grasses the importance of the stage of development in relation to the timing of spray applications was illustrated in the contribution of R. S. L. Jeater (National Institute of Agricultural Botany), who described the complex inter-relationships between species, time of application and the abnormalities induced in the flower primordia and inflorescences.

Three papers were devoted to the means of controlling *Agropyron repens*; in Great Britain the emphasis has been on sodium trichloroacetate, while in Sweden, so Prof. H. Osvald and Dr. E. Aberg reported, comparisons are being made of sodium chlorate, sodium trichloroacetate and 2,2-dichloropropionic acid. Dr. H. P. Allen (Plant Protection, Ltd.) described trials carried out in Malaya with phenyl-substituted ureas for the eradication of *lalang* (*Imperata cylindrica*). Neither 3(3,4-dichlorophenyl)-1,1-dimethyl urea nor 3(*p*-chlorophenyl)-1,1-dimethylurea resulted in complete control of this species unless the rates of application exceeded 80 lb. per acre. On the whole, better results were achieved when the treatment consisted of sodium trichloroacetate at 150–200 lb. per acre.

Prof. G. E. Blackman (Oxford) outlined the programme of investigations being conducted in East Africa by Dr. G. W. Ivens (Colonial Insecticide Research Unit, Tanganyika) in conjunction with the Agricultural Research Council's Unit at Oxford. The main object is to determine how far defoliants and arboricides can be used as means of eliminating tsetse flies through vegetation control. Experiments have shown that aircraft applications of the *n*-butyl ester of 2,4,5-trichlorophenoxyacetic acid are capable of defoliating, or even killing, a range of trees and shrubs found in communities which provide habitats for important species of tsetse fly. Besides applications from aircraft, other uses for such materials are being studied, and there is some evidence from Uganda that in high forest species of valueless trees can be eliminated by spraying the base of the tree with a suitable formulation of an arboricide, such as 2,4,5-trichlorophenoxyacetic acid.

FEDERATION OF MATHEMATICS AND PHYSICS SOCIETIES OF YUGOSLAVIA

CONGRESS IN ZAGREB

THE second congress of the Federation of Mathematics and Physics Societies of Yugoslavia was held in Zagreb during October 4–9, more than six hundred delegates attending. The congress considered a wide range of subjects—in the unanimous opinion of all present, too wide a range—indicating, among other matter, the growth of mathematics and physics in Yugoslavia. Some of the questions the congress examined were the teaching of mathematics and physics in secondary schools; the teaching at universities; and the organization of research in mathematics and physics. Eight sessions were devoted to research papers on mathematics, and nine to papers from the field of physics.

The present writer, being concerned mostly with nuclear physics, can give only a sample subject survey of papers in that field. One should bear in mind that this is the first time in the history of Yugoslavia that research papers in physics were reported at a nation-wide reunion of physicists. Altogether, a hundred and five research papers in physics were given, fifty-seven in the field of particle and nuclear physics, and forty-eight in optics, structure of crystals, geophysics, mathematical equipment, etc. A brief mention of the subjects of some of the papers in the field of nuclear and particle physics will indicate the range of interest. Theoretical research papers included one on the derivation of the nuclear forces from quantum field theory, one on the selection rules in meson theory and another two with Coulomb excitation of nuclei. Two communications dealt with the measurement of cosmic rays underground. A series of papers was on nuclear spectroscopy: beta decay of carbon-14, decay schemes of cæsium-133, cæsium-134, tungsten-185, etc. Other topics considered were the angular distribution in beryllium-9 reactions with deuterons, Auger spectrum of thorium B, the positive particles purported to be accompanying the beta decay of phosphorus-32, the duration of fission, etc. A number of papers dealt with neutron sources, neutron diffusion and calculations of distributions of neutron fluxes. The Stefan Institute of Ljubljana reported on the construction of a mass spectrograph, the Boshkovich Institute of Zagreb on the design of a cyclotron in the range of 20 MeV., and the Kidrich Institute of Belgrade on the functioning and improvement of the ion beam of a Cockcroft–Walton accelerator of 1·5 MeV.

At the final plenary session the congress adopted a series of decisions to be brought to the attention of the Yugoslav Government and the general public. Those pertaining to physics stressed the necessity of developing research in physics at the universities and urged greater material support of the Physics Department of the University of Belgrade. A systematic study was recommended for the development of physics in the country in the light of the development of its economy and the development of physics abroad. Especially underlined was the necessity for a more balanced development of physics research, with support for other branches of research in physics at least equal to that given to nuclear studies. There was considerable discussion, though no formal decision was taken, on the question of starting a central Yugoslav review of physics. At the congress an opinion was expressed that since physics in Yugoslavia is in the process of standing on its own feet, there should be, from an organization point of view, greater autonomy and independence of physics and mathematics activities in Yugoslavia. This point of view was reflected in the election of officers for the executive committee of the Federation, when Prof. G. Kurepa, a mathematician from Zagreb, was elected president, and Mr. A. Milojevich, a physicist from Belgrade, as secretary for physics.

STEVAN DEDIJER

ASSOCIATION OF SCHOOL NATURAL HISTORY SOCIETIES

ANNUAL EXHIBITION, 1954

THE annual exhibition of the Association of School Natural History Societies was held in London at the British Museum (Natural History) on November 6. The main contribution this year was made by member schools, one-third of which exhibited; this was a larger proportion than hitherto and resulted in the welcome criticism that the supply of bench space was too limited.

In spite of the lateness in the year, a wide variety of living material was exhibited. A collection of freshwater gastropods by Oundle School admirably illustrated the importance of accurate identification in limnological work. Bishop's Stortford College had reconstructed with living plants a quadrat from a derelict railway siding, and St. Paul's School, London, displayed living specimens to illustrate a genetical investigation of the shaker mutant in mice. Next year the London exhibition will be held in mid-October. It is hoped that this will encourage schools to produce even more living material.

Where it was impracticable to bring living specimens, most schools had brought preserved ones. University College School, London, filled a long bench with specimens illustrating the littoral biology of Skokholm, while Haileybury and Imperial Service College displayed a collection of the butterflies of France, made by present members of their Society. Lord Wandsworth College, Hampshire, showed a specimen of the water-beetle, *Agabus affinis*, which is a new record for the vice-county of North Hampshire. Further 'new records' were exhibited by naturalists of Kimbolton School who, in their survey of an overgrown Huntingdonshire orchard, have added seven new naturalized species, including *Anemone ranunculoides*, *Doronicum pardalianches*, *Tulipa sylvestris* and *Ornithogalum nutans*, to their county flora.

Many schools made good use of charts, diagrams and photographs to illustrate their work. Those exhibited by Bishop's Stortford College—on starling ringing, watches for visible migration and other ornithological problems—were exceptional for combining complexity with clarity, many being three-dimensional. Dulwich College and Reading School also provided well-documented accounts of their surveys. An interesting item was the 16-mm. colour film of the emergence, from the pupa, of a hornet clearwing moth, filmed by a member of Oundle School. Several schools demonstrated techniques which they had found useful, such as the plant-recording scheme shown by Uppingham School, and a method of mounting seaweeds demonstrated by Orange Hill Girls' Grammar School, Middlesex.

In addition to exhibits by member schools, there were displays by the Botanical Society of the British Isles, the British Naturalists' Association, the School Nature Study Union, the Universities Federation for Animal Welfare and several organizations connected with the British Museum (Natural History).

The increase in the number and size of exhibits received this year is an encouraging sign for the Association. Yet there are many members whose distance from London is such that they cannot attend. It is difficult for them, particularly if they are boarding schools, to arrange to bring a party to London; there is usually no possibility of being away from school overnight. For the benefit of its more distant members, the Association plans to hold an additional exhibition in Leicester next year. This should be within easy reach of schools situated in the Midlands and Northern England.

O. N. BISHOP

FINANCIAL EFFECT OF LABOUR TURNOVER

THE Research Board of the Faculty of Commerce and Social Science, University of Birmingham, has published a further monograph in its series of "Studies in Economics and Society", this latest being on "The Financial Effect of Labour Turnover", by Dr. F. T. Pearce*. The monograph, which is a mimeographed production, can be divided conveniently into three sections. The first section, of sixty pages, reviews many variants of the analytical definition of 'labour turnover' and its complement 'labour stability'. Not unnaturally, the author concludes that the definition adopted by the Birmingham School is to be preferred. This defines the rate of turnover as the number of employees who leave in a given period and have to be replaced expressed as a percentage of the average number employed during the period.

It should be pointed out that the rate so defined confuses current trends with the past economic fortunes of the employing company. A number of recent surveys (including one carried out by the Birmingham School) have established that the rate of labour wastage diminishes as length of service increases. If $F(t)$ is the proportion of an entrant group remaining in employment after t years service, if the rate of wastage $\varphi(t)$ is defined (by analogy with the demographer's 'force of mortality') by

$$\varphi(t) = -\frac{\mathrm{d}}{\mathrm{d}t}\{\log F(t)\},$$

and if n_j is the number of entrants into the firm during the year j, then the rate of labour turnover for the year x, to a first approximation, may be written:

$$\frac{\sum_t n_{x-t}\,F(t+\tfrac{1}{2})\,\varphi(t+\tfrac{1}{2})}{\sum_t n_{x-t}\,F(t+\tfrac{1}{2})}$$

Clearly the numbers n_{x-t} depend only upon past history and have no bearing upon current man-power problems. Equally clearly the formula will yield different rates of turnover for firms with identical rates of wastage but varying in their rates of growth or decay. This confusion of past and present makes it difficult to find any useful meaning for the calculated rate.

The second and largest section, which occupies the next hundred and ten pages, is an essay in accounting. A preliminary chapter outlines the theoretical approach and is followed by two detailed case studies. This section considers the effect on profits of the elimination of *all* labour wastage, and of all those extra charges which are incurred by management (for example, reserves of labour) in order to keep production flowing in spite of constant change in the labour force. A given output yields a gross profit margin of £P and requires N man-hours of 'direct' labour. If all workers had been experienced men, the same output would have required $N - l$ man-hours. The difference is due to the lower output of recruits during their first 21 weeks of employment. The 'ineffective' l hours are a fraction $l/(N-l)$ of the notional 'effective' time worked. The consequential loss of profit is assumed to be £$Pl/(N-l)$. The computation of 'ineffective' time rests upon a comparison of the piece-work earnings of recruits and experienced workers. The additional cost of 'indirect' labour is also estimated.

---

* The Financial Effect of Labour Turnover. By Dr. Frank T. Pearce. (Monograph A.4 of the Research Board, Faculty of Commerce and Social Science, University of Birmingham.) Pp. 228; 1954. 15s.

The value of these painstaking case-studies is difficult to assess. The author has made a courageous attempt to provide a theoretical basis for his procedures, but the information he needs is just not available. Consequently, he is forced into numerous assumptions, particularly of linearity, that seem quite unreal. Moreover, the initial assumption of zero wastage is quite unattainable, except perhaps for isolated cases of very small concerns. Can it really be said that we are measuring the financial effect of labour turnover if we compare the actual outcome of a year's trading with what might have happened if the impossible had been achieved? The last, and shortest, section is an excellent summary of the remainder of the book. H. SILCOCK

SWEATING MECHANISM IN THE DOMESTIC BUFFALO

By DR. E. S. E. HAFEZ and M. M. SHAFEI
Faculty of Agriculture, Cairo University

WATER evaporation from the surface of the skin is the major factor in thermal regulation in mammals. Water comes to the surface as insensible perspiration, which is a physical process, and as sensible perspiration or sweating, which is a physiological process affected by the microanatomy, histology and surface area of sweat glands, as well as the blood and nerve supply of the gland.

We have investigated, by histological methods, the sweating mechanism in the domestic buffalo. Skin specimens from sixteen different regions of the body of three adult male buffaloes have been examined. Bouin's fluid was used for fixation and terpineol for clearing. Embedding was carried out under a vacuum of 67 cm. mercury using paraffin wax (m.p. 50° C.). Serial sections were cut at 25 μ and stained by Delafield's hæmatoxylin and 1 per cent aqueous eosin.

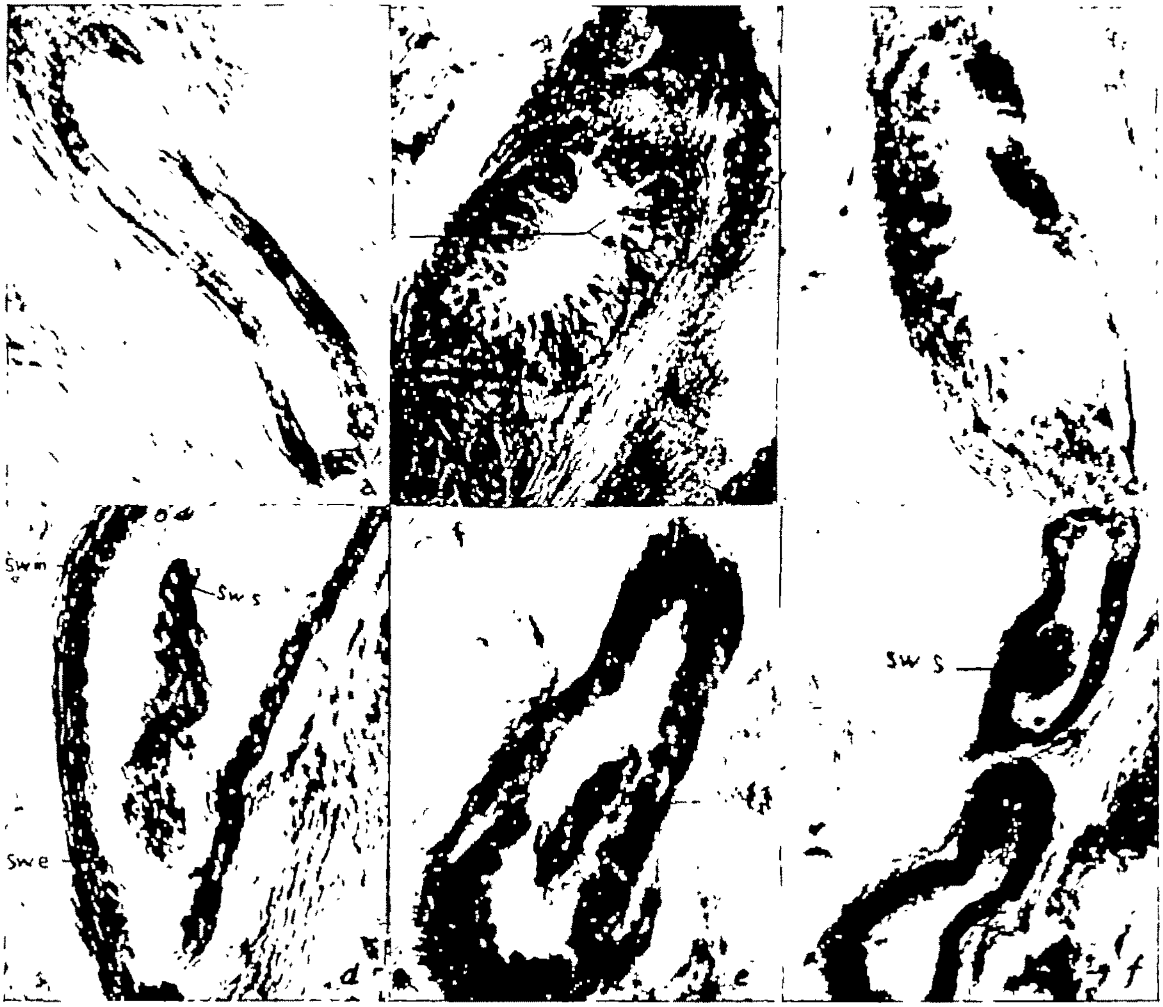

Fig. 1. Successive stages in the formation and intraluminal transformation process of the secretion of sweat glands in the buffalo (× 250)

(a) First formation of the cytoplasmic protrusions from the glandular epithelial cells
(b) Globular protrusions attached to the cells
(c) Chains of the globular protrusions
(d) Detached globules aggregated in the lumen
(e) Fusion of the globules
(f) A gel-like homogeneous material; note that the glandular epithelium is similar to (a)

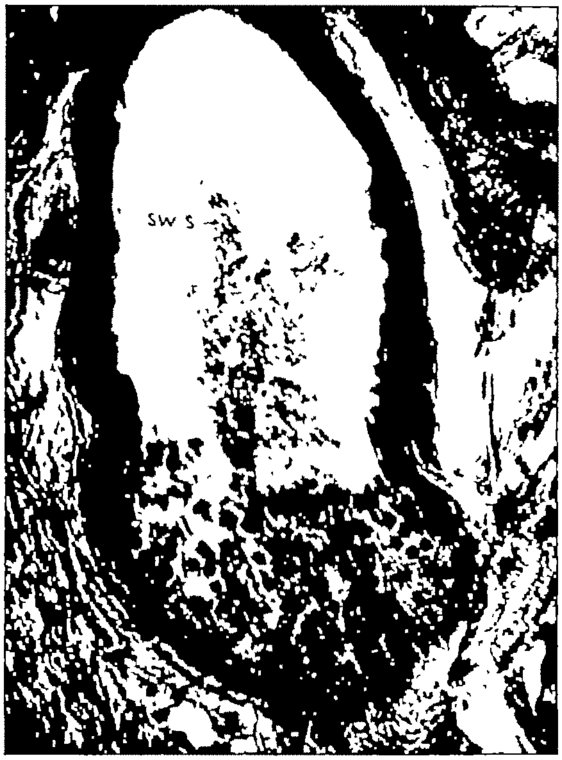

Fig. 2. Simple form of sweat glands in buffaloes (× 250). The glandular epithelium is composed of cubical or flattened cells with small nuclei. The material inside the gland consists of fine granules

In the buffalo, the body of the sweat gland is oval and convoluted, and the duct is twisted at its attachment to the body. The blood supply of the gland is very poor. The body wall is composed of two structures: an outer myoepithelium and an inner layer of glandular epithelium. The gland showed two types of active cells. In the first, a typical apocrine type, the glandular epithelium was made up of columnar epithelial cells with spherical nuclei and cytoplasmic protrusions at the apical portion. The lumen of the gland contained a stainable material which varied in form from separate globular pieces to homogeneous gel-like regions (Fig. 1). In the second type, the glandular epithelial cells were cubical or flattened, with small nuclei, the gland lumen was often empty and some glands contained a fine precipitated substance (Fig. 2).

Both types of glands were observed in the same section of skin and the apocrine form predominated. It would appear that the apocrine glands in the buffalo have only one phase in different stages, and that this stage of secretion is merely preparatory to the ensuing phase. The hypothesis of intraluminal transformation from coarse granules to a fluid-like substance[1] is thus supported. The microanatomy of the sweat gland may be involved in determining the form of secreted substance and may affect the expulsion of sweat. In the buffalo, the twisted duct delays the emptying of the sacular body; this may induce a back pressure which interferes with the elaboration of sweat substance.

Further work is needed to correlate these histological findings with the physiological background of the sweating mechanism. The chloride concentration in bovine skin will be important in determining the nature of insensible perspiration often observed in certain body regions such as the base of the ear, lateral and ventral neck, axilla and groin. Geographical locality of the animal will probably also affect the sweating mechanism.

This work was carried out at the Animal Breeding Research Farm and the Agricultural Zoology Department, Cairo. Thanks are due to Prof. A. L. Badreldin for his encouragement and suggestions. Work is still in progress and detailed results will appear elsewhere. [Aug. 2.

DIGESTIBILITY OF A SAMPLE OF PASTURE GRASS BY CALVES

By D. G. ARMSTRONG, T. R. PRESTON
and R. H. ARMSTRONG

School of Agriculture, King's College, University of Durham

THE possibility of rearing calves on pasture grass from an early age has recently received a considerable amount of attention in Great Britain. The method, which possesses certain economic advantages, has been common practice in New Zealand for a number of years.

Relatively little information exists concerning the utilization of grass by calves. Conrad and co-workers[1], in a study of the effect of rumen inoculations on the digestibility of roughage by young calves, determined the digestibility of lawn clippings, and one of us (Preston, unpublished results) has obtained preliminary figures using fæcal index techniques with the grazing animal. In view of the limited observations available and the need for confirming coefficients of digestibility obtained by fæcal index methods, it was decided to determine the digestibility of a sample of pasture grass by calves aged 10–12 weeks. To allow for the material being fed in the fresh condition, the cold-storage technique developed by Raymond *et al.*[2] was used.

A uniform sample of herbage from a long-established ley was cut on May 25 at the pre-flowering stage. Botanical analysis showed it to contain 91·9 per cent of grass and 5·7 per cent of clover. Accurately weighed quantities of the herbage (15 lb. or 20 lb.) were placed in sacks, which were immediately frozen and cold-stored at 0–5° F. The above amounts were estimated to provide a daily intake of 3 lb. or of 4 lb. of dry matter. As every ten sacks were filled, a 200-gm. sample was taken for dry-matter determination and for the provision of a representative sample.

Four unrelated Ayrshire male calves each reared from birth on pasture, and 34 gal. of milk were put into metabolism crates at the age of nine weeks. Fæces were collected in rubber bags, the bags and harness being based upon a design supplied by Dr. K. L. Blaxter. During the experimental period, which comprised a 10-day preliminary and a 10-day collection period, each animal received the contents of one sack of herbage daily. Calves 1, 3 and 4 were fed 15-lb. quantities; calf 2, by reason of its greater live weight, was fed 20 lb. Feeding times were 9.0 a.m., 11.30 a.m., 2.30 p.m. and 5.0 p.m. With the first and last feed of each day, a gelatine capsule containing 2 gm. chromium oxide (Cr_2O_3) was given. When first fed the frozen grass, calf 3 scoured badly, but quickly recovered following the administration of 20 mgm. of aureomycin on three consecutive days. The remaining calves were dosed simultaneously.

The large weights of fæces voided necessitated the bags being changed twice daily. The weights of fæces were determined by weighing the bags prior to, and immediately after, use. After the contents of each bag had been thoroughly mixed, duplicate 80–100 gm. samples for dry matter were weighed on to tared pieces of grease-proofed paper and thinly spread by means of a spatula to ensure efficient drying. The papers were dried to constant weight in a 'Unitherm' oven at 100° C. Using this technique, agreement between duplicates was invariably excellent. Aliquots of the fresh fæces (10 per cent by weight) were transferred to waxed cartons and kept in cold storage until the end of the trial, when they were bulked to provide representative samples.

The representative samples of wet fæces were treated as follows: 150 gm. was intimately mixed with approximately 100 gm. water in a 'Magimix' blendor, and accurately weighed quantities of the resulting suspension were analysed for dry matter, nitrogen and 'macerate crude fibre'[3]. The remainders of the bulked samples were oven-dried at 60° C. for 48 hr., ground and afterwards analysed for residual moisture, ash, ether extract and crude fibre, by the conventional methods. All samples were further analysed for lignin by the method of Norman and Jenkins as modified by Common[4], and for cellulose by the method of Norman and Jenkins[5]. Chromium oxide was determined according to the procedure of Schürch, Lloyd and Crampton[6].

Table 1. ANALYSIS OF GRASS AND THE DIGESTIBILITY COEFFICIENTS DETERMINED FOR CALVES

	Analysis of feed (per cent of dry matter)	Digestibility coefficients				
		Calf 1	Calf 2	Calf 3	Calf 4	Mean
Dry matter	—	74·6	74·5	78·5	72·4	75·0
Organic matter	92·76	76·6	76·9	80·5	74·5	77·1
Crude protein	13·57	60·1	58·9	65·7	54·5	59·8
Ether extractives	3·69	44·0	43·3	52·9	42·2	45·6
Crude fibre	25·41	78·7	79·0	82·9	77·3	79·7
Nitrogen-free extractives (by difference)	50·09	82·5	82·8	85·3	80·9	82·9
Cellulose	35·22	83·2	85·4	87·7	79·8	84·0
Lignin	3·79	2·1	−7·1	14·7	2·4	3·0

The analysis of the grass and the digestibility coefficients determined are shown in Table 1. While, in general, the digestibility coefficients for calves 1, 2 and 4 show satisfactory agreement, the values obtained for calf 3 are consistently higher. The high digestibility of the organic matter and of the cellulose fraction in particular, and the relatively low value for the apparent digestibility of protein, are noteworthy features of the results. Lignin is clearly almost indigestible.

TABLE 2. CHROMIUM OXIDE RECOVERY

Weight fed (gm.)	Weight recovered in fæces (gm.)				Mean percentage recovery
	Calf 1	Calf 2	Calf 3	Calf 4	
40·00*	41·10	40·78	38·90	42·79	102·30±1·93

* The capsules were guaranteed to contain 2 gm. chromium oxide with a maximum variance of 3 per cent.

From the results shown in Table 2, it can be seen that, with perhaps the exception of calf 4, the recovery of chromium oxide in the fæces has been very satisfactory.

It has already been noted that only one of the calves (calf 2) received the higher intake of 20 lb. a day throughout the experimental period. Before the conclusion of the collection period, calf 3 was clearly capable of eating more than the 15 lb. offered. That this underfeeding may have been responsible for the more efficient digestion of the grass by this animal is suggested by the work of Mitchell *et al.*[7], who, in experiments with steers, showed that the digestibility of dry matter in a ration increased as the level of feed was reduced.

Perhaps the outstanding feature of the results is the very high digestibility of dry matter in the fresh herbage. The coefficients of digestibility for cellulose are even higher. Figures of this magnitude can only reflect an advanced development of the rumen, which is surprising considering the age of the calves. It will be recalled, however, that the calves had been reared on grass from birth, during which period live-weight gains of up to 1 lb. a day were made, and certainly their appearance denoted good paunch development. It should be added that similar values for dry matter and cellulose digestibility, namely, 72·0 per cent and 82·0 per cent, were obtained by Conrad *et al.*[1] during the course of feeding freshly cut lawn clippings to nine-week old calves.

The relatively low apparent digestibility of the protein is difficult to account for in view of the high coefficients obtained for dry matter. It may be that they result from the excretion of considerable quantities of metabolic nitrogen in the fæces. Blaxter and Wood[8] have quoted a value of 2 gm. metabolic fæcal nitrogen per 100 gm. dry matter excreted, for very young calves; and if this factor is used to correct the values for nitrogen excretion, the mean true digestibility coefficient of the protein is found to be 82·9 per cent.

The satisfactory recovery of chromium oxide obtained in this instance would appear to justify the use of this substance as a reference material for indirect digestibility studies with calves.

In studies on the digestibility of herbage, Raymond *et al.*[9] have calculated a regression equation for sheep which relates organic matter digestibility with (1) macerate crude fibre content in fæces ($y = 93 \cdot 42 - 0 \cdot 6582\,u$, where y is digestibility of organic matter and u is per cent macerate crude fibre in fæces on an organic matter basis), and (2) nitrogen in fæces ($y = 44 \cdot 85 + 7 \cdot 947\,v$, where v is per cent nitrogen in fæces on an organic matter basis). Applying regressions 1 and 2 to the results obtained in the present experiment, the mean calculated digestibility coefficients for organic matter are 78·69 and 77·56, respectively. These values compare favourably with the determined value, namely, 77·14. While further confirmatory evidence is needed, these results would suggest the possibility of using the above regressions in digestibility studies with calves at pasture.

We wish to thank Mr. G. A. Cragghill for his assistance in the investigation. [Sept. 24.

Direction of Polarization of Proton Spin produced by Elastic Scattering

BEAMS of high-energy protons with spin polarization are produced by scattering unpolarized protons from nuclei[1,2]. If the protons are scattered elastically, the polarization is considerably larger than if the scattering occurs by inelastic processes[3,4]. A theoretical interpretation has been suggested by Fermi and others[5], which demonstrates that the polarization of the elastically scattered beam may be accounted for as a consequence of the spin orbit-coupling postulated in the nuclear shell model of Mayer and Jensen. This hypothesis gives correctly the magnitude of the observed polarization, and in addition predicts the direction of the polarization. In particular, if the scattering is to the right at small angles, this hypothesis requires the predominant spin direction to be downward.

The object of the present experiment was to measure the direction of the polarization, a property impossible to determine by the usual double-scattering experiments. The measurement depended on knowledge of the polarization resulting from interference of the energy-levels involved in the elastic scattering of protons on helium in the energy region 1–15 MeV. From the cross-section data for this reaction, Critchfield and Dodder[6] have evaluated the phase shifts. In fact, two representations of the data were found, for both of which the ^2P phase shifts were positive (attractive potential). In one solution the ^2P-states were inverted, and in the other solution they were normal. Interference of the states of the doublet produces a polarization of the scattered protons. Heusinkveld and Freier[7] observed the second scattering asymmetry resulting from this polarization, and by its magnitude at a given energy were able to conclude that the P-state is an inverted doublet.

This information allows one in principle to determine the spin direction of a beam of polarized protons by a similar experiment.

In the present investigation, a 435-MeV. 60 per cent polarized proton beam was produced in the cyclotron by scattering elastically the circulating protons of 450 MeV. maximum energy at 14° from an internal beryllium target. The polarization of the emergent proton beam was determined in the usual way, by measuring the asymmetry of elastic scattering from beryllium at the same angle, namely, 14°. Then the protons were slowed down by passing through a thickness of copper approximately equal to their mean range, after which they were expected still to be polarized[8]. The protons of various low energies in the region 0–20 MeV. were then collimated carefully. Next they entered a scattering chamber filled with helium at atmospheric pressure (see Fig. 1). Nuclear emulsions (Ilford *E*1) were placed to right and left in the scattering chamber in such a way that protons scattered by the collimating system could not reach them, and in such a way that protons scattered in the horizontal plane by helium and at ± 90° to the beam entered the emulsion in a direction normal to the surface.

There were approximately 30,000 high-energy protons arriving per second at the copper attenuator. The flux, however, was drastically reduced by scattering during energy degradation and subsequent collimation. The frequency of occurrence of events in the plates is found to be in rough agreement with the estimated slow-proton flux and with the elastic scattering cross-section of helium.

From the direction in which a scattered proton enters the emulsion and from its energy as determined by its range in the emulsion, one computes the energy of the proton before scattering. Only those events are accepted for measurement in which the proton enters the emulsion within 45° of the normal to the surface of the emulsion. At present, approximately fifty events have been found. In Fig. 2 the number of events is plotted against the incident energy computed for the scattered proton.

For comparison purposes we have calculated the helium cross-sections for a proton beam polarized with spin down, for scattering to right and to left, as a function of energy and angle using the phase shifts at present available[6,9]. The differential cross-sections have been integrated over the solid angle of

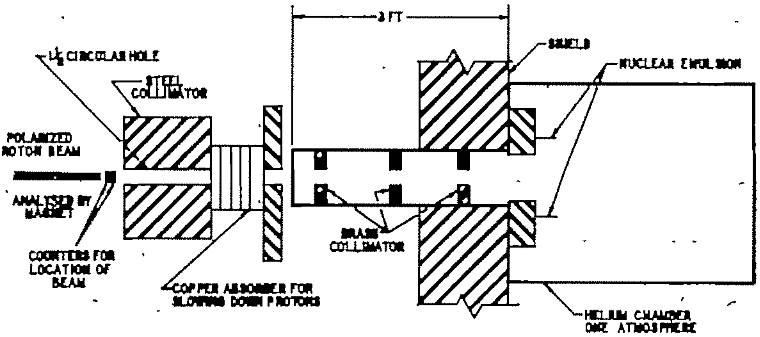

Fig. 1. Schematic drawing of experimental arrangement for exposure of nuclear emulsions to energy-attenuated polarized beam

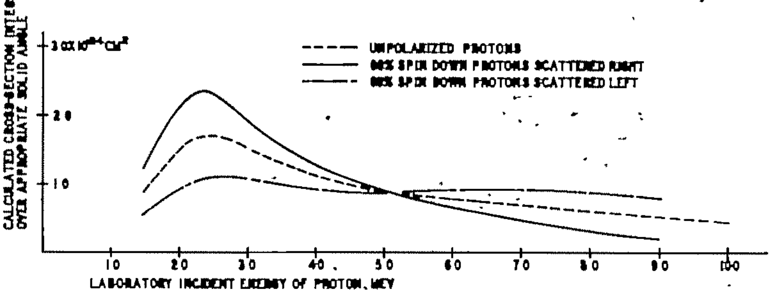

Fig. 2. Helium elastic scattering cross-sections for protons versus proton energy, calculated from phase shifts, and integrated over solid angle in which scattering events were accepted. The cross-section for unpolarized protons scattered either to left or right is shown, and also the cross-sections for protons 60 per cent polarized with spin down, scattered to left and to right. For the case of protons 60 per cent polarized with spin up, the designations on the two latter curves are interchanged

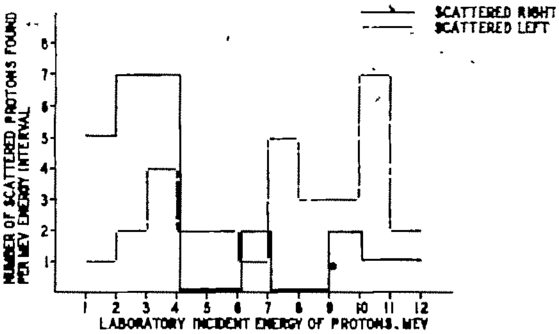

Fig. 3. Number of polarized protons observed to be scattered to left and to right between θ = ± 45° and θ = ± 135° laboratory angle shown plotted versus energy of incident proton

acceptance and corrected for the fact that the incident beam is 60 per cent polarized. The resultant cross-sections, plotted in Fig. 3, show right scattering stronger than left scattering near 3 MeV., and at 7–11 MeV. right scattering weaker than left scattering. If, on the other hand, the incident beam were assumed polarized with spin up, the cross-sections in Fig. 3 for scattering to the left and right would be interchanged.

The results in Fig. 2 show, however, a behaviour similar to the curves of Fig. 3, within the large statistical errors. Consequently we reach the tentative conclusion that the proton beam incident on the helium is polarized with spin down.

We now return to a consideration of the first scattering which produced the polarized beam. The first scattering, in the cyclotron, was to the right, for which, for an attractive potential, $\vec{L}$ is directed downward.

But the tentative conclusion allowed by the foregoing evidence is that the spin of the right scattered beam is downward, that is, parallel to $\vec{L}$. Then the elastic scattering is stronger at small angles for spin parallel to $\vec{L}$, in agreement with the proposal[8] that the polarization is due to the spin orbit-coupling effective in nuclear shell structure.

We hope to publish soon a more detailed discussion of this experiment, including better statistics of the scattering events. We are grateful to Robert March for help in plate scanning, and to Dr. Frank Solmitz, who helped in the calculation of the cross-sections in Fig. 2.

This investigation was supported by a joint programme of the U.S. Office of Naval Research and the U.S. Atomic Energy Commission.

Chemisorption on Metals

The criterion for chemisorption on metals is the occurrence of an electron switch, the resulting complex having a dipole moment orientated vertically to the surface. The method of contact potentials has been employed to evaluate the magnitude of the change in work function of the surface as a result of chemisorption, and recently the vibrating condenser method has been used for the same purpose. There are some disadvantages attached to these methods. In the former, thermal radiation from the emitter may alter the composition of the chemisorbed layer on the cold surface; in the latter, the presence of a large amount of metal and the assumption that only parts of the system are affected by the introduction of the gas militate against the exact determination of the dipole-moment surface-coverage (μ, θ) relationship.

We have recently explored the potentialities inherent in the determination of this relationship by photoelectric methods. The method consists essentially in measuring the photo-current produced on illumination of a freshly formed metallic mirror with ultra-violet light of suitable wave-lengths transmitted through a quartz window. From the adsorption isotherms it is possible to evaluate the coverage as a function of dosage and to make simultaneous measurements of the photo-currents. Some values for the change in work-function potential are given for $\theta = 1$ in Table 1.

Table 1

Surface	Ta—H	Ta—CO	Fe—H	Fe—CO	Co—H	Co—CO	Ni—H
potential in volts	+0·43	−0·67	−0·19	−1·15	−0·06	−0·27	−0·12

Of great interest is the fact that the curve of dV against surface coverage (θ) is not linear over the whole range of coverage but shows a curvature at the commencement. In addition, as seen from Fig. 1, when θ is equal to or greater than 0·6, there is a falling off in the value of the apparent dipole moment, thus providing additional support to the view, based upon experimental determination of the adsorption isotherms and on heats of adsorption, that at least in many cases of chemisorption the bond-strength between adsorbate and adsorbent is not constant but changes as the electron density in the

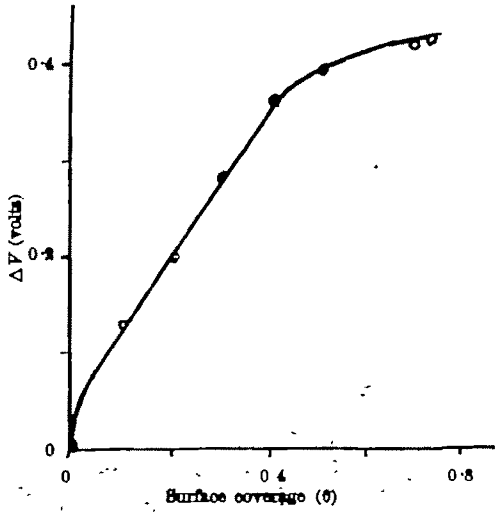

Fig. 1. Variation of surface potential with surface coverage (hydrogen adsorption on tantalum)

metal surface undergoes changes as a result of chemisorption.

It is hoped to publish a more detailed account of the method shortly.

Transition Temperature of Polymethyl Methacrylate at Ultrasonic Frequencies

Pulse method measurements by Krishnamurthi and Sastry[1] and Melchor and Petrauskas[2], of the variation of ultrasonic velocities with temperature for polymethyl methacrylate ('Perspex'), showed that the transition temperature was independent of frequency (0·5–10 Mc./s.). Protzman[3], using an optical diffraction method, found that the transition point for 'Plexiglas II' (unplasticized 'Perspex') varied from 63° C. at 3 Mc./s. to 49° C. at 11 Mc./s. The authors claim an accuracy of ± 1 per cent for their results, which are shown in Fig. 1, together with some of my own results. The following comments are made on these results.

(*a*) Results on different samples of commercial plastic materials are likely to vary. This has recently been pointed out in low-frequency work on polymethyl methacrylate by Deutsch, Hoff and Reddish[4]. Heating may also cause irreversible changes in plastic materials.

(*b*) Protzman's[3] velocity results differ from Melchor's[2] by a maximum of 6 per cent, the agreement being good at room temperature. One possible error in Protzman's[3] work is that several watts of ultrasonic energy could have been transmitted into the sample. This would cause internal heating, and the observed temperature in the surrounding liquid would not be the true sample temperature. Protzman does not state the energy used, but he mentions that 500–1,000 volts (radio-frequency) were applied to the quartz crystal. This is much higher than is usual. This internal heating would be dependent on frequency and could cause the variation of transition temperature with frequency. A further possible error, if the transducer was small and high energy was used, may have been that ultrasonic waves were transmitted into the oil-bath from the sample. If this occurred, then the light beam would have been diffracted in the liquid as well as the solid. Willard[5], using an improved optical diffraction method for plastics, allows a parallel ultrasonic beam to be transmitted into the solid and surrounding liquid medium. He then corrects his velocity results for the variations in velocity of sound in the liquid with temperature.

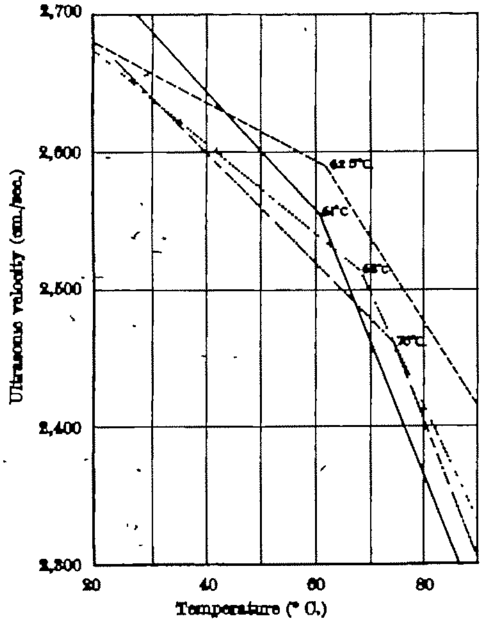

Fig. 1. Ultrasonic velocity – temperature curves for polymethy methacrylate. — — —, Protzman's results at 3 Mc./s., frequency-dependent; ....., Hatfield's results at 350–750 kc./s.; —·—·, Melchor and Petrauskas's results at 0·5–10 Mc./s.; ———, Krishnamurthi and Sastry's results at 1–6 Mc./s.

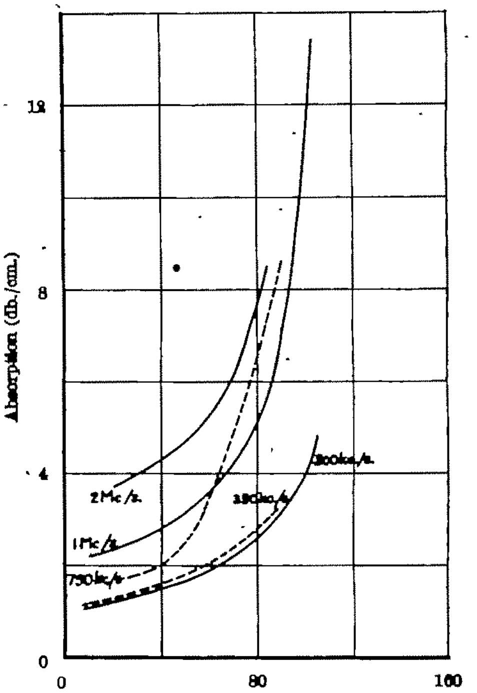

Fig. 2. Absorption in polymethyl methacrylate. ———, Melchor's results; – – – –, Hatfield's results

(*c*) The slopes of the curves obtained by Krishnamurthi[1] and Melchor[2] are similar, but the transition temperatures differ by approximately 14° C. Melchor points out that the determination of this transition temperature to within a few degrees is not easy because of the high absorption of polymethyl methacrylate, at temperatures above 60° C. and frequencies greater than 1 Mc./s. Fig. 2 shows results obtained by Melchor and myself (accuracy ± 1 db.) for the variation of absorption with temperature at frequencies less than 2 Mc./s.

(*d*) The pulse method has been greatly improved by Mason[6], and it would be interesting to repeat the pulse experiments on polymethyl methacrylate using this method.

(*e*) Fig. 1 shows my velocity measurements for polymethyl methacrylate plotted against temperature at frequencies less than 1 Mc./s. These results were obtained using a low-power (less than 1 watt) continuous-wave phase method[7]. The absolute accuracy of this method is not as good as the attainable accuracy of the optical diffraction or pulse method, particularly for materials the acoustic impedances of which differ appreciably from those for water or oil, but the low absorption at high temperatures at less than 1 Mc./s. is not a source of error. The velocity results at 350 and 750 kc./s. are not significantly different, and the transition temperature over a series of runs varied between 66° and 71° C. These results are similar to those obtained by Melchor[2] and by Krishnamurthi[1].

Low-temperature Sintering of Titanium Dioxide for Ceramic Capacitors

THE investigations carried out by Berberich[1], Von Hippel[2] and Wainer[3] and their associates on titanium dioxide point to certain optimum firing conditions. In particular, a temperature of 1,350° C. is found to be suitable for obtaining most of the desirable electrical characteristics. Among these characteristics may be specially mentioned low water absorption, high permittivity, high insulation resistance and low loss-angle. From the known values of the two principal permittivities of the single crystal of rutile, the permittivity for randomly oriented powdered rutile would be about 114. The values of the permittivity reported in the literature vary from 96 to 100, and water absorption is known to be about 0·1 per cent. The rutile form of titanium dioxide used in their experiments was prepared by calcining commercial quality titanium dioxide, probably of the anantase type, at 1,350° C.

In some large-scale experiments carried out at the National Physical Laboratory of India on a particular brand of commercial quality of titanium dioxide bearing the trade name "Rutiox CR" (Kronos), it has been possible to obtain ceramic bodies with excellent dielectric properties when fired at temperatures as low as 1,100° C. in electric furnaces. It was not found necessary to calcine the material first, and a straight firing schedule was adopted which gave well-sintered bodies. The neutral atmosphere of the electric furnace and the partially reducing atmosphere of a gas furnace gave identical results. It was also found that the sintering temperatures were not very critical, as reported by earlier investigators. Satisfactory bodies could be obtained when fired over a range of temperatures from 1,100° to 1,400° C.

X-ray diffraction studies and the density measurements showed that the raw material was of the rutile crystalline form. Measurements by microscope of particle-size indicated sizes generally in the range 1–5 microns, with crystal edges sharp, indicating that the titanium dioxide was perhaps manufactured in these particle sizes, by chemical processes and not by grinding calcined material.

Some typical values obtained with bodies prepared as stated above are: water absorption, 0·01 per cent; permittivity, 110.

It would appear that the low sintering temperatures, coupled with good electrical properties, are due to the rutile crystalline form and the finely divided active state of the titanium dioxide used.

Fuller details of the experiments will be reported elsewhere. We are indebted to Sir K. S. Krishnan for his advice and guidance.

Polymerization Reactions occurring during Dinitrophenylation of α-, β- and ω-Amino-acids with Sanger's Reagent

NUMEROUS papers have been published concerning the identification and determination of amino-acids by the dinitrophenylation method introduced by Sanger[1]. We are not aware, however, of any indications in the literature about the occurrence of polymerization reactions during dinitrophenylation. In an attempt to work out a procedure for the quantitative determination of minute amounts of ε-aminocaproic acid and its linear oligomers, we have found that such polymerization reactions do occur. Similar results have been found during dinitrophenylation of other ω-amino-acids and of glycine and β-alanine. Since these side-reactions may lead to complications in investigations on the separation and determination of dinitrophenyl amino-acids in general, it seems useful to communicate these facts briefly.

Dinitrophenylations were carried out by Sanger's method[1], using 1-fluoro-2,4-dinitrobenzene in aqueous ethanol in the presence of sodium bicarbonate. Isolated products as well as samples of reaction mixtures were analysed by chromatography on paper strips using a descending technique (see Table 1). Since pure ε-aminocaproic acid and the nearly pure synthetic dimer and trimer of the acid[2] were at our disposal, chromatographic spots of the corresponding dinitrophenyl derivatives could be easily identified. With the eluent used, R_F-values decrease with increasing molecular weight (Table 1). The purity of our samples of aminocaproic acid was checked by chromatography of aminocaproic acid as such (method worked out by van der Want[3], slightly modified).

From a mixture of initial composition 0·75 m.mol. ε-aminocaproic acid, about an equimolecular amount of fluorodinitrobenzene and 1·6 m.mol. sodium bicarbonate in 10 ml. aqueous ethanol (25 per cent of water), reacting at room temperature, samples were taken at successive intervals. Each sample served to place ten spots (of 10 µl. each) on a chromatographic strip. Depending upon the duration of reaction, one or more additional spots appeared on the eluted chromatograms besides the expected spot of dinitrophenyl–aminocaproic acid. From their R_F-values relative to that of the latter, these spots could be identified as the dimer, trimer and so on.

Table 1. – Polymerization Products produced during Dinitrophenylation of the Monomers and their Relative R_F-values (R_F-values of the corresponding Dinitrophenyl-monomers taken as Unity)

Chromatography on Whatman No. 1 paper (soaked in 0·1 *M* citric acid and dried in air) with a mixture of *n*-propanol (diluted with water to spec. gr. 0·818), glacial acetic acid (containing 1·5 per cent of water) and kerosene (b.p. 100–140° C.) in the volume proportions 20 : 6 : 100

ω-Amino-undecanoic acid	ω-Amino-heptanoic acid	ε-Amino-caproic acid	β-Alanine	Glycine	Dinitro-phenyl-
1	1	1	1	1	monomer

—	—	0·10*	—	—	pentamer

* Only found once in a dinitrophenyl-aminocaproic acid sample synthesized by a method not mentioned in this communication.

This proves that polymerization occurs during the dinitrophenylation reaction.

Mixing the reagents and reaction products (including the products of other side-reactions known to occur, like dinitrophenol, dinitrophenetol) in various combinations and examining the products eventually obtained, we found that at least the components fluorodinitrobenzene, aminocaproic acid (and dinitrophenyl–aminocaproic acid) must be present to produce polymerization.

As pointed out recently by Bunnet and Davis[3] and by Zahn and Kocklauner[4], dinitrophenyl halogenides behave as acid halogenides in many respects. Frankel, Liwschitz and Zilkha[5] have found that acetyl chloride can produce polymerization of amino-acids even at room temperature. It seems that fluorodinitrobenzene can give rise to analogous reactions.

Other amino-acids such as ω-aminoheptanoic acid, ω-amino-undecanoic acid, β-alanine and glycine also show some polymerization when dinitrophenylated by the method described above.

In the dinitrophenylation of aminocaproic acid with reaction times from 1 to 120 hr., the proportion of the dimer to the dinitrophenyl–aminocaproic acid varied from about 2 to 20 mol. per cent (also depending upon the water content of the mixture). After 120 hr., only about 40–50 per cent of the expected quantity of dinitrophenyl–aminocaproic acid was present, and total conversion of ε-aminocaproic acid into the dinitrophenyl compounds was about 60 per cent. This was established by elution of the spots from the paper, followed by ultra-violet light absorption measurements.

More complete conversion of aminocaproic acid into dinitrophenyl–aminocaproic acid and its oligomers was achieved only after evaporation of the reaction mixture until dry at elevated temperatures. This is in agreement with the work of Schroeder and Le Gette[6], who reported that conversion is enhanced by raising the concentration of the amino-acid in the reaction mixture.

From the other amino-acids we have not measured the proportions of the polymerization products, but from the intensity of the spots on the chromatograms it can be estimated that the proportion of dinitrophenyl–amino-acid dimer found under equal reaction conditions is in the following order of increasing magnitude:

Glycine < β-alanine < ε-aminocaproic acid ~ ω-aminoheptanoic acid ~ ω-amino-undecanoic acid.

Since dinitrophenyl–glycine dimer formation is very small, this may also pertain to other α-amino-acids and may explain the favourable results achieved by Mills[7] for glycine, aspartic and glutamic acid. Nevertheless, certain losses in quantitative dinitrophenylation experiments with α-amino-acids may be due to polymerization, and the occurrence of parasite spots on the chromatograms would then also be accounted for.

Table 1 gives a review of the relative R_F-values of the dinitrophenyl oligomers of the various amino-acids.

We are indebted to Dr. G. M. van der Want[2] (Delft) for supplying the samples of ε-aminocaproic acid dimer and trimer, and to Dr. H. Zahn (Heidelberg) for a supply of fluorodinitrobenzene. Grateful acknowledgment is made to Mr. F. Woutman (Arnhem) for carrying out the ultra-violet extinction measurements and to Miss E. A. Smit for performing the numerous experiments. This work has arisen from a programme of fundamental research on polyamides carried out in co-operation with the Plastic Research Institute T.N.O., Delft, and sponsored by AKU (General Rayon Union), Arnhem, and Netherlands State Mines, Geleen.

Alternation in the Adsorption of Aliphatic Acids on Porous Carbon

Alternation in many of the properties of successive members in homologous series of solid long-chain compounds is well known. We are reporting the direct observation of a similar alternation in the maximum adsorptions of mono-[1] and di-carboxylic acids from aqueous solutions on two series of coconut shell charcoals of different degrees of activation. Some alternation in the adsorptions of these acids on a single 'Norite' charcoal was found indirectly by Linner and Gortner[2], who made a Langmuir extrapolation of their isotherms to maximum adsorption.

In the present work the adsorptions were measured by the change-in-titre method. The results for a more activated charcoal are given in Fig. 1. As the activity[1] of the charcoals decreased, the degree of alternation in adsorption decreased. In the case of the mono-acids, alternation disappeared entirely for the lesser activated charcoals; apparently it was masked by molecular sieving.

The alternation in adsorption is compared with the alternation in melting points of the acids in Fig. 1. The scales for the two acid series were displaced so that each series would appear separately. The arbitrary elements in the graph are the temperature and adsorption scales themselves, and the approximate overlapping of the melting point and the adsorption of one of the acids in each acid series. The results suggest that there is a close correlation

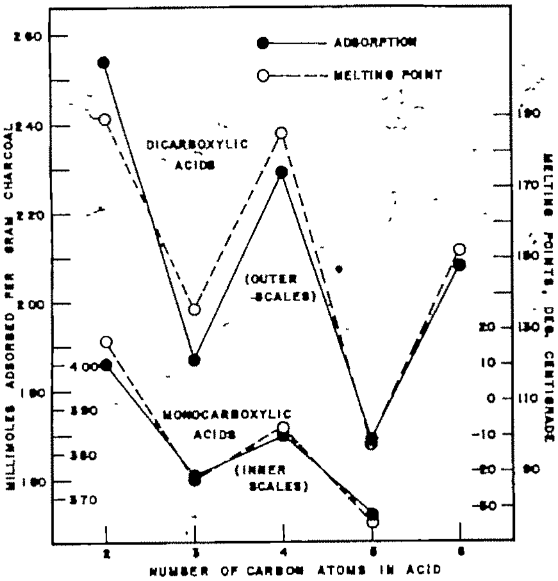

Fig. 1

between the alternations in melting points and adsorptions. Thus it would appear that the saturated adsorbed film is in a highly oriented state such as in crystalline solids.

We believe that an explanation for the alternation in the case of adsorption must be looked for in differences in lateral packing rather than in the lengths of the chains[3]. Moreover, our observations tend to refute the suggestion that adsorption from binary mixtures on porous adsorbents is always by a pore-filling mechanism[4]. Rather, they strongly suggest that adsorption of the aliphatic acids from aqueous solutions on porous carbons is in unimolecular layers.

We wish to acknowledge financial assistance from the National Research Council of Canada for a part of this work, and also helpful discussions with Prof. R. U. Lemieux. A complete report of the work is appearing in the *Canadian Journal of Chemistry*.

Identification of an Artefact on Chromatograms of the Keto-acid 2,4-Dinitrophenylhydrazones

DURING a study of plant keto-acids carried out by one of us (G. H. N. T.) under the direction of Prof. F. C. Steward at Cornell University, an unknown substance, hereafter designated compound I, was found in the keto-acid fraction of all plant tissues examined[1]. This substance was isolated in crystalline form (sint. 206°, decomp. 214°) from the keto-acid dinitrophenylhydrazone fraction of *Mentha piperita* leaves by elution from an alumina column with 1 per cent sodium carbonate. Its position on chromatograms was similar to that of the slower-moving spot of pyruvic acid dinitrophenylhydrazone (Fig. 1, ref. 1). The pyruvic acid spot developed a chocolate colour when sprayed with alkali, whereas compound I gave a yellow colour. On hydrogenation, compound I yielded a ninhydrin-reactive substance (compound II) which was chromatographically similar to γ-aminobutyric acid (Fig. 2, ref. 1). The infra-red absorption spectrum of compound I did not display the carboxyl peak characteristic of α-keto-acid dinitrophenylhydrazones.

We have utilized the same procedures[1] for a study of the relation between the keto-acids and the fixation of carbon-14 dioxide in leaves. Compound I consistently recurred on chromatograms of the keto-acid dinitrophenylhydrazones. Although under favourable conditions radiocarbon was incorporated by the leaf into most of the recognized keto-acids, it never entered compound I. We therefore suspected that it might be an artefact.

When the reagent (2,4-dinitrophenylhydrazine) was dissolved in ethyl acetate and extracted with alkali in the manner used in the keto-acid method, a brown gum was recovered from the alkaline extract. Chromatograms of this gum showed two main spots: one, a fast-moving brown spot; the other, identical in position with compound I. Alkali-extracted and recrystallized 2,4-dinitrophenylhydrazine still gave these substances on a second extraction with alkali.

A survey of the literature showed that an alkali-soluble compound, 1-hydroxy-6-nitro-1 : 2 : 3 benzotriazole, is obtained on treating 2,4-dinitrophenylhydrazine with alkali. Accordingly, some of this compound was prepared by refluxing 2,4-dinitrophenylhydrazine with hydrazine hydrate[2], and its physical and chemical properties were compared with those of compound I isolated from *Mentha* leaves. The two substances were found to be identical with respect to infra-red spectra, melting characteristics and chromatographic co-ordinates.

This finding has an important bearing on the current use of 2,4-dinitrophenylhydrazine as a reagent for the detection of keto-acids. The artefact may interfere on one-directional paper chromatograms of keto-acid dinitrophenylhydrazones because its position overlaps that of pyruvic acid dinitrophenylhydrazone. The effect may, however, be minimized by avoiding an excess of reagent. In addition, the artefact may be partially separated from the slower-moving spot of pyruvic acid dinitrophenylhydrazone with certain solvents as shown in Table 1.

Table 1

	Rf values		
	Solvent *A*	*B*	*C*
1-Hydroxy-6-nitro-1 : 2 : 3 benzotriazole	0·56	0·43	0·81
Pyruvic acid dinitrophenylhydrazone (slower-moving spot)	0·60	0·40	0·84

A, *t*-amyl alcohol/ethanol/water (ammonia vapour), 9/1/2.
B, *t*-amyl alcohol/*n*-propanol/ammonium hydroxide, 13/1/6.
C, 0·5 per cent sodium carbonate.

We wish to acknowledge the helpful suggestions of Dr. M. Kates.

Classification of the Antifungal Antibiotics from *Bacillus subtilis*

SEVERAL papers have recently appeared describing substances produced by *Bacillus subtilis* which exhibit antifungal activity with only incidental antibacterial action. Though the chemical and physical properties of these substances were not thoroughly investigated, it appears that some of them are similar and can be grouped together. Table 1 summarizes the known properties of nine of these antifungal antibiotics. It shows that whenever tested, these substances proved to be extracellular, acidic, non-dialysable and heat-stable polypeptides, not affected by pepsin and trypsin. They are soluble in polar, and insoluble in non-polar, organic solvents. Peptides I, II and III have an acid equivalent weight in the neighbourhood of 1,000, and an acid dissociation constant of about $pK = 5 \cdot 5$; as acidic polypeptides, they are soluble in alkali and insoluble in water and in dilute acids. Similar solubility properties were found for other substances of this group, as given in Table 1.

Two-dimensional paper chromatograms, made at Rehovot, of the acid hydrolysates of I, II and III, using phenol–water and butanol–acetic acid, showed that these three peptides are composed of the same amino-acids. In all three substances aspartic acid, glutamic acid, serine, threonine and tyrosine predominated, while alanine, leucine, phenylalanine and valine were found in relatively small quantities. An unidentified ninhydrin-positive spot was found in the neighbourhood of aspartic acid (Tint and Reiss[5] stated that their most purified samples of II contained the first five amino-acids only). A similar amino-acid composition was reported for IX[7]; aspartic acid, glutamic acid, tyrosine and leucine were found in VI[9]. No tryptophan, basic or sulphur-containing amino-acids were found in these antifungal antibiotics. The amino-acid composition of these substances is in agreement with their acid character and relatively low nitrogen and amino-nitrogen content.

Further evidence for the similarity of I, II and III may be found in their antibiotic spectra, as tested by us under identical conditions (Table 2). A survey of the literature showed that the other antifungal antibiotics listed in Table 1 have similar antimicrobial properties. No complete comparison of the antibiotic spectra could, however, be made, since different assay methods and various organisms have been used for the study of these substances.

Although the three other antifungal polypeptides produced by *B. subtilis*, namely, fungistatin (antibiotic *XG*)[8], mycosubtilin[11] and "rhizoctonia factor"[8], are in many respects similar to the above nine substances, they differ in the following important properties: fungistatin is an amphoteric polypeptide, containing basic amino-acids and tryptophan; mycosubtilin is intracellular, does not dissolve in the lower aliphatic alcohols, does not contain glutamic acid and serine, and its acid equivalent weight is 1,980; "rhizoctonia factor" is dialysable, insoluble in butanol and ethanol and is inactive against *Aspergillus niger*. Thus these three cannot be included in the same group.

It is suggested that the nine substances listed in Table 1 be classified under one name. Although eumycin was the first substance of this group reported, it was not clearly enough characterized to warrant designating the whole group by this name. We

Separation of Proteolytic Enzymes of *Clostridium histolyticum*

PREVIOUS attempts to separate the proteolytic enzymes found in culture filtrates of *Cl. histolyticum* have been largely unsuccessful. Methods for preparing proteinase free of collagenolytic activity have been described[1]; but collagenase free of other proteolytic activity has never been obtained.

Complete separation with more than 80 per cent recovery of all enzymatic activity has now been achieved by a simple method of fractional precipitation with saturated ammonium sulphate solutions neutralized with ammonium hydroxide to a pH of 7·5.

The starting material was a 2 per cent solution of crude enzyme prepared by precipitating the culture filtrate with 400 gm./l. of solid ammonium sulphate[1,2]. To this solution the saturated ammonium sulphate was added slowly and stepwise at room temperature. After each stepwise addition the precipitate was centrifuged off, dialysed and freeze-dried, and a further amount of saturated ammonium sulphate added to the clear supernatant.

In this way four peaks of different enzymatic activities could be distinguished: a proteinase peak (*A*), a collagenase peak (*B*), an amidase-esterase peak (*C*) and a peptidase peak (*D*) (see Fig. 1).

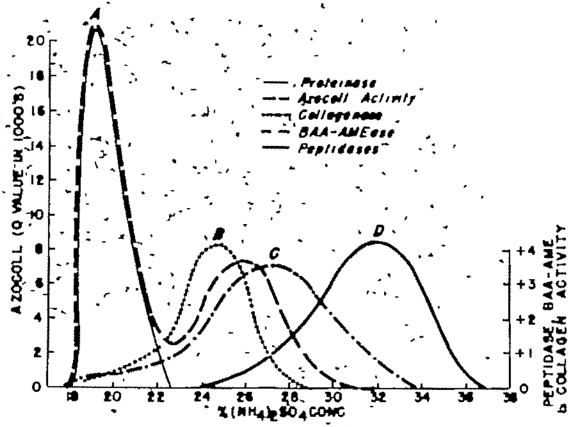

Fig. 1. Fractional precipitation of crude enzyme

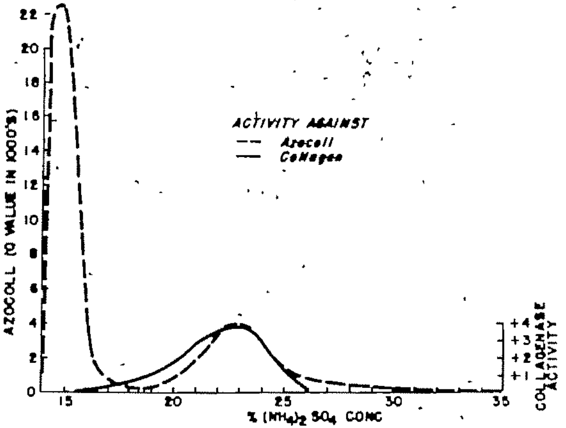

Fig. 2. Reprecipitation of proteinase peak

The proteinase of peak *A* is identical with that previously described by us[1] and referred to as δ-enzyme. However, this fraction is free of blood-group *A* substance and has a potency fifty times greater than that of our previous preparations. By refractionation (see Fig. 2) it has been completely freed of collagenase and peptidase activity and most of the amidase-esterase. It is active against the following substrates: azocoll[2,1], gelatine, hide-powder, casein, hæmoglobin, coagulated egg albumin, coagulated bovine plasma albumin and fresh fibrin clots (Table 1).

At 24–27 per cent saturation (peak *B*) collagenase is reprecipitated, free of proteinase and low in peptidase activity; amidase-esterase is still present.

Table 1. SPECIFICITY OF *Cl. histolyticum* ENZYMES

	Proteinase	Collagenase	Amidase-esterase	Peptidases
Azocoll	+	+	?	0
Collagen	0	+	–	0
Gelatine	+	+	?	?
Casein	+	0	0	0
Hæmoglobin	+	0	0	0
Egg albumin	+	0	0	0
Bovine plasma albumin	+	0	0	0
Fresh fibrin clots	+	0	0	0
Benzoyl arginine amide (cysteine-activated)	0	0	+	0
Arginine methyl ester (cysteine-activated)	0	0	+	0
Leucylglycine (cobalt-activated)	0	0	0	+
Leucylglycylglycine	0	0	0	+
Valyl deca peptide	0	0	0	+

The collagenase is active against native collagen, azocoll and gelatine, but has no effect against casein, hæmoglobin, albumin and fibrin (see Table 1).

The amidase-esterase is the third enzyme to be precipitated from solution, reaching a point of maximum precipitation at about 28 per cent (peak *C*). At this point most of the collagenase has been salted out. Because of the large difference in ratio of collagenase to amidase at peaks *B* and *C* respectively and for other reasons which will be published elsewhere, we consider the amidase-esterase a separate enzyme. It attacks benzoyl arginine amide and arginine methyl ester and is strongly activated by cysteine (Table 1).

The peptidase peak (*D*) appears to correspond to several peptidases not separated from each other as yet. The later fractions (32–35 per cent) are free of collagenase, other proteinases and amidase-esterase. One constituent is a cobalt-activated dipeptidase attacking leucylglycine, leucylalanine, etc., and the other is an aminopolypeptidase needing no activation. It is active against leucylglycylglycine and the decapeptide synthesized by Erlanger *et al.*[4] which contains valine at the terminal amino-position. Activity against other peptides is being studied (Table 1).

Production of Unsaturated Uronides by Bacterial Hyaluronidases

PNEUMOCOCCAL hyaluronidase has been shown to hydrolyse only the glucosaminidic bonds of hyaluronate[1]. The pneumococcal enzyme and other bacterial hyaluronidases have further been shown to differ from hyaluronidases of animal origin in their thermal lability, and in their capacity to hydrolyse hyaluronate faster and more completely. The main product of exhaustive hydrolysis of hyaluronate by testicular hyaluronidase is a tetrasaccharide[2], whereas the end-product of the action of pneumococcal hyaluronidase is a fraction having the reducing values of a disaccharide[1].

The pneumococcal product differs markedly, however, from N-acetylhyalobiuronic acid, the repeating unit of hyaluronate[3], and of the oligosaccharide fractions obtained on digestion with testicular hyaluronidase[2] as demonstrated in Table 1. The values indicate that the bacterial product is a disaccharide. It is also produced with hyaluronidases of varying degree of purity prepared from cultures of streptococci, staphylococci and *Clostridium welchii*.

Table 1

Analysis	'Bacterial' disaccharide	N-acetyl-hyalobiuronic acid
Reducing sugar* (hypoiodite)	1·05 mgm./mgm.	0·70 mgm./mgm.

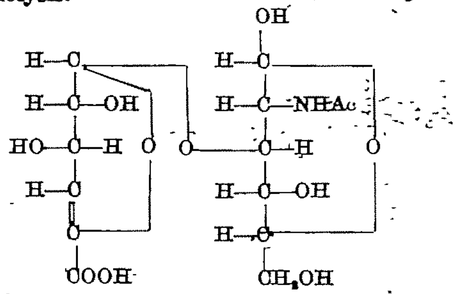
RF	0·38	0·24

* As glucose.

On acid hydrolysis of the bacterial disaccharide, D-glucosamine has been obtained as the hydrochloride in a yield of 74 per cent and characterized as the carbobenzoxy compound. The bacterial disaccharide shows the following behaviour, which further distinguishes it from N-acetylhyalobiuronic acid. It consumes one mole of bromine, and has an absorption maximum at 230 mμ typical of α-β-unsaturated carbonyls, and yields on ozonolysis oxalic acid. On hydrogenation with palladium on charcoal, the disaccharide takes up two moles of hydrogen. This product, homogeneous by paper chromatography, no longer absorbs at 230 mμ, fails to give the carbazole reaction of uronic acids and is not decarboxylated on heating with acid. Its aldehydic function, however, is still intact as evidenced from the hypoiodite titration and the colour value in the modified Elson–Morgan reaction[4]. The results indicate a 4–5 unsaturated uronide of the following tentative structure (I). The consumption of the second mole of hydrogen appears to be due to hydrogenolysis.



(I)
'Bacterial' disaccharide

The exhaustive hydrolysis of hyaluronate by bacterial enzymes yields the unsaturated disaccharide in almost quantitative yield, whereas from tetrasaccharide, obtained with testicular hyaluronidase, the bacterial enzymes yield equal quantities of N-acetylhyalobiuronic acid and the unsaturated disaccharide (the acid itself was recovered unchanged after incubation with bacterial hyaluronidase). When the hydrolysis of hyaluronate by bacterial enzymes is not allowed to go to completion, oligosaccharides are isolated which differ chromatographically from those obtained from testicular digests. Resistance of these fractions to β-glucuronidase[4] indicates that the non-reducing glucuronidic end-group is modified. These results strongly suggest that the double bond is formed during hydrolysis of the glucosaminidic bonds by dehydration of the glucuronidic groups.

One enzyme appears to catalyse both the hydrolysis and the dehydration. The mechanism of the reaction may be explained by the assumption that the water of hydrolysis of the hexosaminidic bonds is furnished by the adjacent uronidic group instead of by the medium. The glucosaminidic linkages of hyaluronic acid are claimed to be in the 3-position on the basis of a negative periodate consumption (see ref. 3). Therefore the double bond either migrates into the conjugated 4–5 position or the original bond actually is not in the 3- but in the 4-position. The latter is more probable.

The dehydrative hydrolysis is not limited to hyaluronate and to oligosaccharide fractions prepared from it. The naturally occurring polysaccharide chondroitin and partly desulphated oligosaccharide fractions obtained by acid hydrolysis from chondroitin sulphate *A*[6] are hydrolysed by bacterial hyaluronidases with concomitant dehydration.

It is to be expected that other glycosidic bonds will be hydrolysed dehydratively and that unsaturated sugars and products derived from them similar to those described here may occur in Nature.

Lungworms (*Metastrongylus* spp.) in Pigs, and their Development in the Guinea Pig

THE three species of the genus *Metastrongylus*, *M. apri* Gmelin, *M. pudendotectus* Vostokov and *M. salmi* Gedoelst, occur in the pig; but the last has only been found in the Belgian Congo, the United States and the U.S.S.R. The two former species occur in Great Britain[1]; but opinion differs as to their incidence, probably because of a failure to recognize the rather inconspicuous lesions they produce in adult pigs (personal replies to a questionnaire).

During the past two years we have studied the incidence of the worms in pigs at a bacon factory in Cheshire, the occurrence of lungworm eggs in the fæces of pigs, the development of lungworms in earthworms (intermediate host), and the experimental infection of laboratory animals. A short note on the first year's findings has already appeared[2], and the present communication records briefly the most important results of the work of two years. Detailed accounts will be published elsewhere.

The discovery of virus pneumonia in pigs and the suggestion that it is very widespread and causes considerable economic loss[3] make it desirable to distinguish it from other conditions that cause pigs to cough.

Of 1,308 bacon pigs examined between February 1954 and March 1954, the lungs of 18·2 per cent were infected. These pigs came from 224 individual consignments, 44·2 per cent of which contained one or more infected pigs; this means that lungworms existed in almost half the batches of bacon pigs coming to the factory from north-west Britain. We have found lungworms as frequently in other areas, too. Many naturally infected pigs harbour only very light worm burdens, and the lesions in such pigs may be confined to the extreme tip of the diaphragmatic lobe. Often the parasites can be found only if the finest bronchi are opened. The usual lung lesions in bacon pigs are pale wedge-shaped areas of emphysema, situated mainly along the postero-lateral border of the diaphragmatic lobe. Pneumonic changes are seldom associated with these lesions, and are much more common in the apical and cardiac lobes.

Examination of a large number of samples of fæces from naturally infected pigs failed at first to yield lungworm eggs. The explanation was later found to lie in the failure of saturated sodium chloride solution (spec. grav. 1·200) to bring the eggs to the surface when 2-gm. samples of fæces were examined by centrifuging at 1,500 r.p.m. for three min. Experiments showed that saturated sodium chloride yielded only 1/200 to 1/20 of the eggs given by saturated magnesium sulphate ($MgSO_4,7H_2O$, spec. grav. 1·285) used in the same way. Table 1 shows the counts of lungworm eggs with the two flotation solutions for six samples of fæces chosen from a total of twenty-three samples examined. Magnesium sulphate will reveal with great accuracy very small numbers of lungworm eggs, and counts of 2–5 eggs per gm. have been obtained regularly over a series of weeks from infected pigs. Low egg-counts are common in naturally infected pigs and would be missed if the usual routine fæces examination with sodium chloride were used. The mean of the counts for the twenty-three samples was 4·4 eggs per gm. for sodium chloride and 294 eggs per gm. for magnesium sulphate. That the superiority of magnesium sulphate is not due solely to its specific gravity is shown by the fact that a saturated solution diluted to specific gravity 1·200 was almost as effective as the fully saturated solution. The failure of sodium chloride to float the eggs of the pig lungworms was pointed out nearly twenty years ago by Russian workers[4], who also showed the value of magnesium sulphate; but their findings do not seem to have been widely recognized.

Cultures of various species of earthworms have been successfully established[5] and a number of species have been infected with lungworms. *Eisenia foetida* was the species most easily cultured and infected, but is rare on pig pastures. *Allolobophora nocturna*, *A. caliginosa*, *A. chlorotica* and *Lumbricus rubellus* have also been infected, and all these species occur in pasture land.

Table 1. COMPARISON OF SATURATED SODIUM CHLORIDE AND SATURATED MAGNESIUM SULPHATE FOR FLOTATION OF EGGS OF LUNGWORMS (*Metastrongylus* SPP.) IN THE FÆCES OF NATURALLY AND EXPERIMENTALLY INFECTED PIGS

Sample No.	Eggs per gm. of fæces

6 (*N*)	0	6

(*E*), Experimentally infected; (*N*), naturally infected

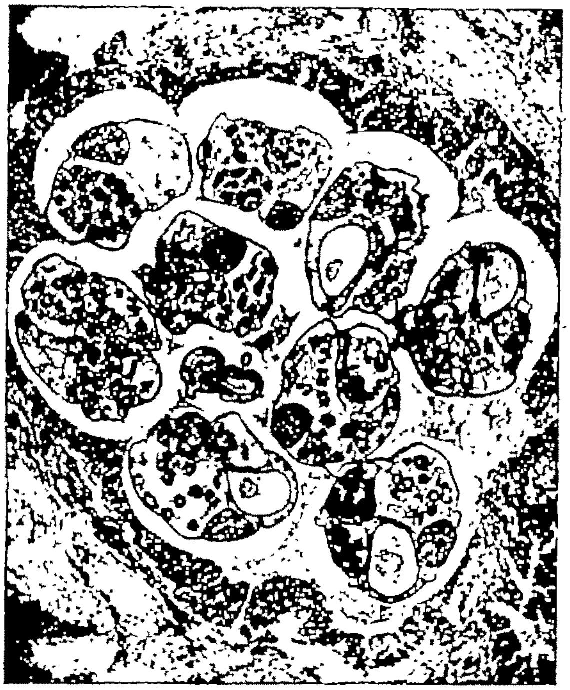

Fig. 1 Section through bronchus of guinea pig infected with *M. apri* showing ten adult worms in the lumen. Eight of the nine females show embryonated eggs containing larvæ. Hæmatoxylin and eosin. × 145

Guinea pigs have proved to be the most satisfactory laboratory animal for infection with the pig lungworm, and a total of 116 young guinea pigs (150–350 gm. body-weight) have been given third-stage infective larvæ by mouth. More than 50 per cent have become infected with lungworms, and in the most recent experiments the infection-rate has been 80–100 per cent. In one experiment with eight animals, all became infected and six of them showed at autopsy four to seven weeks later a large number of mature adult female worms containing viable embryonated eggs (Fig. 1).

Lungworm eggs, identical in appearance with those found in pigs, were found in the fæces of three of the guinea pigs by magnesium sulphate flotation. Eggs recovered from the female worms in the guinea pig lung produced infective larvæ in *Eisenia foetida*, and a guinea pig was successfully infected with these larvæ. Previous workers have reported that experimental infections in guinea pigs have failed to yield fertile eggs[5], and we believe this to be the first such record. We are now trying to adapt the lungworm to the guinea pig in the hope of obtaining 100 per cent infection with regularity. This would provide a useful experimental tool for the study of lungworms in domestic stock, because there would then be both an intermediate host (earthworm) that could be maintained and infected with ease and also an experimental animal as definitive host (guinea pig) which would be available in large numbers for chemotherapeutic tests and biological studies.

In our experimental work on guinea pigs, we have confirmed the finding of Porter[6] that basophilia is a feature of infection in the guinea pig and have found it to be preceded by an eosinophilia, which soon subsides. Re-infection when the basophilia and eosinophilia had lapsed produced a recurrence of the same blood picture.

All our experimental work on pigs and laboratory animals has been carried out with *M. apri*, which is the more common of the two species in the pig in Great Britain. *M. pudendotectus* is usually present along with *M. apri*, but in much smaller numbers. We have not found *M. salmi*.

These investigations were carried out with a grant from the Agricultural Research Council.

Effect of Acetate on the Fasting Blood-Sugar Level of the Rat

Chari and Wertheimer[1] state that intraperitoneal injection of acetate (100 mgm./100 gm. body weight ?) into rats "caused hypoglycæmia and increased alkalosis" but give no details of their experiments. In view of the known interrelationship between glucose and acetate in the ruminant[2], it was considered of interest to investigate this point further.

Blood samples were taken by heart puncture under 'Nembutal' anæsthesia from adult rats previously fasted for 17 hr. before and 30, 60, 120 and 180 min. after intraperitoneal injection of sodium acetate or an equivalent amount (in terms of sodium) of saline. The solutions injected were isotonic at a dose-rate of 100 mgm./100 gm. body-weight and of twice this concentration at a 200 mgm./100 gm. level. Acetate appears to produce a slight hyperglycæmia of short duration, the effect being most marked when 100 mgm./100 gm. was given; in no case was there any subsequent marked hypoglycæmia compared with the results in animals given saline at the corresponding level. The type of diet apparently had little, if any, effect on the response to acetate. A transient hyperglycæmia may be expected in view of the known effect of acetate on depressing glucose uptake by various rat tissues[3,4] and agrees with the findings of Reid in the sheep[2].

The effect of incorporation of acetate in the diet of weanling rats was also investigated. One group of seven animals was given 8 gm. of powdered rat cubes per rat daily, mixed with milk, and a second group of six animals was maintained on the same diet mixed with increasing amounts of acetate in the form of a solution of sodium acetate. It was evident from the growth curves that only a limited amount of acetate could be incorporated in the diet if growth was to continue normally. The maximum level tolerated appears to be of the order of 13 per cent of the diet. Acetate fed at this level had no effect on 17-hr. fasting blood-sugar levels. A transient hypoglycæmia induced in rats on a diet containing

16·5 per cent sodium acetate was presumably largely due to starvation.

A Method of collecting Fluid leaving the Omasum of Sheep

IN ruminants a large proportion of the ingested food is digested in the fore-stomachs. In order to know the final result of this digestion, it is necessary to know the composition of the material leaving the fore-stomachs and the rate of flow at the omaso-abomasal orifice. To study this problem a special cannula has been devised (Fig. 1). It consists of a main tube, *B*, of ebonite (2 cm. internal diameter), into which runs a smaller one, *C* (1 cm. internal diameter). The main tube is 10 cm. long and is connected at one end with a funnel, *A*, of which the diameter of the top is 6 cm. and its height 4 cm. The side tube, *C*, is screwed perpendicularly on to the middle of the main tube. It is threaded on the outside over its whole length, so that an ebonite ring (*D*) of 3 cm. diameter can be screwed on to it, making it mobile over the whole length of the tube.

For the operation, the anæsthetized sheep is put on its left side. The abdominal wall is incised just behind the ribs from the median line about 20 cm. upwards. After opening the abdomen, the abomasum is exposed and a small incision is made in it through which the large tube is slid so that the opening of the funnel fits against the omaso-abomasal orifice, and the main tube lies completely in the abomasal lumen. After screwing the side tube on to the main one, the abomasal wall is sutured. A ligature is put around the abomasum just under the funnel in order to keep the tube in place; when inserting this ligature, care is taken not to damage the main nerves and blood vessels. It is tightened just sufficiently to prevent the funnel from passing through. Just behind the ribs and next to the main incision a stab wound is made in the abdominal wall through which passes the side tube. The various layers of the abdominal wall are then sutured. The ring is screwed on the side tube just up to the skin and the tube is corked.

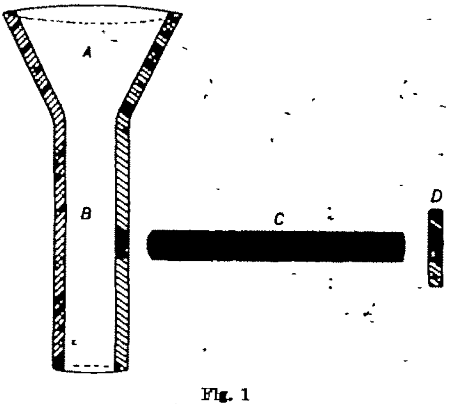

Fig. 1

For the collection of fluid leaving the omasum, a balloon is passed through the side tube into the distal part of the main tube, which is blocked by insufflation of air into the balloon. The fluid leaves the side tube at fairly regular intervals; its dry-matter content varies between 5 and 10 per cent. The *p*H is usually slightly higher than the *p*H of the ruminal fluid.

Living protozoa are found in the fluid. A very great variation has been found in its chlorine content, although this is always much higher than that of the ruminal fluid. The amount of pepsin, usually present in traces, depends upon the position of the front part of the funnel. It has been shown that the cannula does not interfere with the normal movements of the rumen and reticulum.

More detailed results obtained with this procedure will be published elsewhere.

Serous Cells in Brunner's Glands of the Rabbit

IN Brunner's glands of the rabbit's duodenum there are numerous groups of serous-type cells lying among the mucous acini. It has long been believed that these cells are of a nature similar to those of the pancreatic acini. According to Patzelt[1], Schwalbe (1872) was the first to make the suggestion, and he quotes the work of later authors who have added confirmatory evidence: the cells have similar staining reactions to those of the pancreatic acini, and they undergo compensatory hypertrophy after the pancreatic duct is ligated; rabbits so treated remain in good health.

In a previous communication[2], it was pointed out that in sections of rabbit duodenum treated histochemically by Gomori's 'Tween' technique for 'lipase', these serous cells are strongly 'lipase'-positive and stand out sharply among the 'lipase'-negative mucous acinar cells. The suggestion was made that the 'lipase'-positivity might be a point in favour of the above view. This has now been explored further.

It was felt that if it could be shown that the 'lipase' reaction given by these cells is due to true lipase, then the above view would be substantiated very considerably, since true lipase is almost confined to the pancreatic acinar cells. True lipase can be readily distinguished from non-specific esterase by the influence of bile salts upon the activity of the enzyme. It has been demonstrated chemically[3] and histochemically[4] that bile salts activate true lipase and inhibit non-specific esterase. This fact formed the basis of the present work.

Specimens of duodenum from each of six rabbits were fixed in absolute acetone, cleared in benzene, embedded in paraffin and serially sectioned at 7 µ. A histochemical study was made of the 'lipase' activity of the sections, employing a modification of Gomori's 'Tween' technique[5], namely, a method in which the sections are introduced directly into the substrate without prior dewaxing[6]. Adjacent sections of each specimen were taken; one was incubated in the usual 'Tween' substrate bath ('Tween 40' was employed throughout) and the other in a 'Tween' substrate bath containing 0·2 per cent sodium

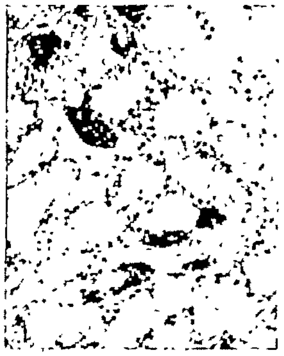

Fig. 1

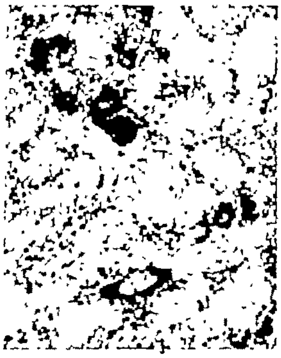

Fig. 2

Fig. 1. Brunner's glands of rabbit duodenum. × 110. 2 hr. incubation in a normal 'Tween' substrate bath. There is a reaction in groups of serous cells lying among the lipase-negative mucous acinar cells

Fig. 2. Adjacent section to that of Fig. 1. × 110. 2 hr. incubation in a 'Tween' substrate bath containing 0·2 per cent sodium glycocholate. Note marked intensification of the reaction in the serous cells

Nuclei were lightly counter-stained with hæmatoxylin

glycocholate. The incubation periods were the same for each of the two sections.

The results were quite definite and striking. After incubation over-night, all the sections incubated in the normal 'Tween' substrate bath showed the usual reaction in the serous cells among Brunner's glands and in the surface epithelial cells of the villi and upper parts of the crypts. In all sections that had been incubated in the presence of bile salt, the reaction in the villi and crypts either had not appeared at all or was very faint (indicating that the enzyme activity there is due to non-specific esterase); but the reaction in the serous cells among Brunner's glands was particularly intense.

In order to demonstrate more clearly that activation of the reaction in the serous cells takes place, adjacent sections were incubated in the two substrates for such short periods as 1, 2 and 3 hr. After 1 hr. there was already a reaction in the sections incubated in the presence of bile salt, but none in those incubated in the normal substrate bath. After 2 or 3 hr., a reaction was present in both sections, but was much more intense in that incubated in the presence of bile salt. A typical result obtained after 2 hr. incubation is illustrated in Figs. 1 and 2.

This experiment shows that these serous cells, like the cells of the pancreatic acini, contain true lipase. Moreover, the reaction is localized mostly in the apical parts of the cells, as it is in the acinar cells of the pancreas. This finding adds strong support to the view that these serous cells in Brunner's glands of the rabbit are of the same nature as the acinar cells of the pancreas.

Biochemical Changes in Cultured Cells

THE *in vitro* culture of blood or bone marrow cells is frequently employed in hæmatological studies. Since it is uncertain how far *in vitro* conditions approximate to *in vivo* ones, it is important to collect as much evidence as possible bearing on the life of cultured cells. It is not enough that they should merely exist in a state of torpor; but there should be some indication of the occurrence of proliferative activity or of cell maturation and differentiation. Although ample morphological evidence of both these processes in bone marrow cells in fluid media has been put forward[1,2], it is desirable to demonstrate that such cultures are also 'biochemically alive'. Measurements of cellular nucleic acids may reveal maturation and differentiation of cells of the hæmopoietic system, for it has already been shown that the ribonucleic acid content of the cytoplasm of primitive marrow cells is much greater than that of the mature differentiated forms[3,4]. We have studied the quantitative changes taking place in nucleic acids during the culture of bone marrow cells.

Some results of a number of experiments on the culture of bone marrow cells from patients suffering from pernicious anæmia, using a standard technique[5], are summarized in Table 1. The nucleic acid content of the culture was estimated by a microchemical method[6] and correlated with the number of cells per cu.mm. The mean amounts of deoxyribonucleic acid phosphorus per cell at 0 hr. and 48 hr. were found, in any one experiment, to be very similar, indicating that the cellular contents of deoxyribonucleic acid phosphorus did not vary during culture.

Grand mean of the 19 cultures at 0 hr. = 8·06 × 10^{-7} μgm. per cell.
" " " " 19 " " 48 " = 8·88 " " " "

The mean content of ribonucleic acid phosphorus per cell, on the other hand, was in most experiments lower at 48 hr. than at 0 hr., indicating cell maturation and differentiation. The most useful information, however, was obtained from consideration of changes in the ratio of ribo- to deoxyribo-nucleic acid phosphorus, for this avoids the errors in cell enumeration. Examination of the figures suggests strongly that a fall in this ratio is the rule, but that the rate of fall varies from experiment to experiment. However,

					17·3338

P', fiducial probability that the true mean difference is not positive that is, $P' = \frac{1}{2}$ (P of Fisher) except in Exp. 6, where $P' = 1 - \frac{1}{2}$ (Fisher's P).

* The 0- and 48-hr. series were treated separately in calculating t. Use of the series of differences leads to $\chi^2 = 29·88$, $P < 0·01$.

we are not concerned here with varying rate of change, or with effects of added substances which, apparently, are unimportant. When each experiment is used for providing independent evidence of a fall in the ratio and the results are pooled by the method advocated by Fisher[7], results are obtained as shown in Table 2. It is evident that, although the fall in the ratio is significant only in experiments 2 and 10, the aggregate evidence for a fall is very significant; $\chi^2 = 34·6676$ with 14 degrees of freedom, $P < 0·01$.

We consider that the results indicate that in these bone marrow cultures maturation and differentiation of cells is proceeding, a process that involves loss of ribonucleic acid phosphorus from the cell, which maintains a relatively constant content of deoxyribonucleic acid phosphorus.

Nuchal Crests in Australopithecines

In his reply to my recent communication in *Nature*[1], Prof. S. Zuckerman questions my statement that direct evidence is available that the Swartkrans prehominid did not have a "powerful and shelf-like"[2] nuchal crest even when a sagittal crest was present.

This evidence is most clearly seen in the Swartkrans skull *SK*.49, the occipital region of which has now been prepared in acetic acid. The skull has been sheared considerably, but the region from slightly posterior to the glabella to approximately the position of the bregma, as well as a good deal of the occipital region, are little disturbed and the bone surface in these regions is so well preserved as to show the minutest details of structure. Approximately five and a half centimetres of the frontal region is preserved in the mid-line, and this bears a low sagittal crest, 2·6 cm. of which is preserved. This crest is lower than those of skulls *SK*.46 and *SK*.48. The well-preserved occipital portion extends from the left mastoid to approximately 1 cm. to the right of the mid-line—here indicated by the posterior end of the sagittal suture and by the inion. In the mid-line the bone surface is undamaged from half a centimetre below the inion to nearly 3 cm. above it. To the left of the mid-line the preserved area is greater. The whole of the superior nuchal line is well preserved on the left side between the mastoid and the inion. A clearly defined but small external occipital protuberance is situated 2·8 cm. below the lambda. The sagittal and lambdoid sutures are here quite apparent. Disturbance of the bone just above the lambda has resulted in both sutures being pulled slightly apart in this region and it is manifest that no fusion had yet occurred. There is no trace of a sagittal crest in the mid-line, along either the 2·8 cm. of perfectly preserved bone from inion to lambda, or on the centimetre of disturbed bone above lambda, where the bone is well enough preserved to have shown it had there been a crest. A small sagittal crest is therefore actually present near the bregma but none in the occipital region, nor does the left temporal line reach anywhere near the mid-line in this region.

The superior nuchal line is very weakly developed for 1·9 cm. to the left of the inion, is then drawn out into a low ridge for a distance of 2·7 cm., after which it is again a barely perceptible line for the remaining 2·4 cm. of the specimen. At its maximum development this ridge is 3 mm. high, measured on the upper side. Even at this point of maximum development the planum nuchale passes downward and forward directly from the ridge crest, that is, the ridge results largely from the planum occipitale being a little depressed just above it. There is, therefore, not even a continuous ridge across this region, let alone a "powerful and shelf-like" nuchal crest.

Zuckerman[1] suggests that the Makapan occiput belonged to an immature individual because the sagittal and lambdoid sutures had not yet completely fused—although he gives no reasons for supposing that this criterion is applicable to the australopithecines. In *SK*.49 the upper post-canine dentition is *in situ* and well preserved. M^1 is so much worn that the enamel is worn through over the protocone and is about to go through over the hypocone, M^2 is worn on all four cusps and M^3 already shows some wear. By any reasonable standards this specimen must be considered fully mature, yet its sagittal and lambdoid sutures are not fused. The corresponding sutures of the Makapan specimen had already started fusing[3], hence there is no reason for supposing that it is not fully mature also. A second calvarial fragment from Makapan has the temporal lines approaching the mid-line fairly closely but not reaching it, and this shows that the point of nearest approach to the mid-line is distinctly anterior to that at which the former specimen is broken. If the temporal lines of the former specimen conform to the same pattern, as they appear to do, then they must have met farther forward and formed a small crest.

SK.48, from Swartkrans, is also a mature adult skull—the molars are in much the same stage of wear as are those of *SK*.49. Although the occiput is distorted and displaced, almost the whole of the right superior nuchal line from near the mid-line to the mastoid is present. This shows a condition similar to that of *SK*.49, except that the central part is drawn out into a ridge which reaches a maximum height of 6 mm. The length of the ridge is about two and a half centimetres. In the bregma region the anterior 2 cm. of a sagittal crest is well preserved. Although the preserved anterior part of this crest is shorter than that in *SK*.49, it is already higher at the point at which the break occurs and was therefore almost certainly an appreciably larger crest. Nevertheless, this specimen, like *SK*.49, did not have a continuous or shelf-like nuchal crest.

Zuckerman says that my description of *SK*.48 differs from the 'official' one. Broom[4] said that "all the lower part of the occiput is preserved, but much crushed forward and upward into the brain region"—which says nothing about the state of preservation of the occiput, merely that in the crushing of the skull it has been displaced forward and upward. I stated[1] that "the greater part of the occiput is present but is a bit distorted and displaced", that is, it is not only displaced but also distorted. Except that Broom said nothing about the distortion, our statements differ only in regard to the exact degree of displacement—which tells nothing about the amount of detail to be observed on the occiput. Zuckerman[2], on the other hand, referring to *SK*.48 and *SK*.46—which were at that time the only skulls mentioned in the literature as having sagittal crests—says, "Unfortunately the occipital region of both skulls is lacking". It might be added that in the introduction to the volume which Zuckerman regards as official we state that it is "only a preliminary account".

Zuckerman doubts the correctness of referring the pelvis and spinal column from Sterkfontein to the Sterkfontein australopithecine on the grounds that "a manifestly human mandible has been found in the same deposits as have yielded the australopithecine apes". The 'human' mandible is presumably that of *Telanthropus*. The pelvis and spinal column were recovered from Sterkfontein, from the same single mass of consolidated breccia as were the several score of australopithecine remains. No other hominoid remains have been found at this site. The *Telanthropus* remains occurred *in situ* at Swartkrans, nearly a mile away, in company with the remains of an australopithecine quite different[5] from that at Sterkfontein. Swartkrans is geologically more recent than Sterkfontein—as is clearly shown by the fact, among others, that *Equus* and *Papio* occur at the former site but not at the latter. To doubt the relationship of the pelvis to the cranial remains at Sterkfontein because *Telanthropus* occurs in a quite different and geologically younger site is clearly inadmissible.

Zuckerman has given much information about the occurrence of nuchal crests associated with sagittal crests in many different primates. The question whether these two were also associated in the australopithecines will not be solved by studying bigger and better collections of modern pongids, monkeys, etc., but by studying australopithecines. So far they have yielded no evidence in support of this thesis, but some direct evidence against it.

J. T. ROBINSON

[4] Broom, R., and Robinson, J. T., *Transvaal Mus. Mem.*, No 6 (Pretoria, 1952).

[5] Robinson, J. T., *Amer. J. Phys. Anthrop.*, n.s., 12, 181 (1954).

THE essential point at issue, which Dr. Robinson contested in his first communication[1], is the general proposition[2] that the presence of a sagittal crest in the skull of an Old World primate implies the presence of a nuchal (= occipital) crest; and further, that if one of the two is absent, it is usually the sagittal crest. "Unless *Paranthropus crassidens* is the one exception to a morphogenetic process common to all known Primates", I therefore suggested that the fact that two presumed female *Paranthropus* skulls were furnished with high sagittal crests implied that they had also possessed powerful occipital crests and an ape-like planum nuchale. In turn this implied a nuchal musculature and a carriage of the head on the vertebral column of the kind that is seen in the ape. I also suggested that this conclusion was consistent with certain other features of the Australopithecine skull.

Dr. Robinson now admits that *SK*.49, a specimen to which he referred before[1] in a few lines, and which he now describes for the first time—and all students of the subject will be grateful to him for this description—has a nuchal crest which is drawn out into a ridge that projected 3 mm. He also now states that the corresponding figure in *SK*.48, which he previously described as having a "well-marked occipital crest"[3], is 6 mm. Nuchal crests which are no more prominent—and indeed some less prominent—will be found in many adult apes. He and I have, therefore, no argument, regardless of the concluding sentence of his communication. Both his specimens possess nuchal or occipital crests, and both conform to the generalization to which he had previously taken exception. His observation that the crests were deficient in the mid-line also fits in with what I was at pains to point out in my previous communication[4]—namely, that in the ape the least prominent part of the nuchal crest is not infrequently in the mid-line, where, indeed, it is sometimes deficient.

For the rest, I fear that I still find it difficult to equate Broom and Robinson's[3] description of the occipital region of *SK*.48 as "very considerably crushed upwards and forwards" with Robinson's present statement[1] that it is merely "a bit distorted and displaced". Nor do I share his assurance (*a*) that it is possible to assess the maturity or otherwise of a fragment of one skull by appealing, via an apparent correspondence of sutural closure, to the dental wear of another specimen; or (*b*) that the question of the relation of post-cranial to cranial fragments in the deposits in which the South African australopithecine fossils have been found is as simply settled as he would have us believe. All that need be said about the belief that *SK*.49 possessed a low sagittal crest anterior to its bregma, but none in the region of the lambda, is that if this condition is regarded as characteristic of all *Paranthropus* skulls, the temporal muscles in this beast must have developed somewhat differently from the way they do in the great apes, and that the condition presumably corresponds to those unusual cases in the gibbon when the temporal lines meet each other, and fuse, just behind the bregma, to form such a crest.

FORTHCOMING EVENTS

Wednesday, December 29

British Institution of Radio Engineers, London Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Discussion Meeting on "Education and Training of Radio Engineers".

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "Gaps in the Knowledge of Applied Mechanics".

Wednesday, December 29—Monday, January 3

39th Conference of Educational Associations (at University College, Gower Street, London, W.C.1).

Wednesday, December 29

At 5 p.m. (in the Friends' Meeting House, Euston Road, London, N.W.1)—Sir Charles R. Morris: "Education and the Family" (Presidential Address).

Friday, December 31

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Mr. J. S. Turnbull: "Lost-wax Process of Precision Casting, 1949–1953".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Laboratory Technician (with experience of food and toxicological analysis) in the University of Edinburgh Department of Veterinary Hygiene and Preventive Medicine—The Secretary to the University, Old College, South Bridge, Edinburgh (January 1)

Research Assistant (with a good honours degree in physics and experience in the design of electronic circuits, and preferably practical acquaintance with television or sound-film recording techniques) in the Department of Physics and Mathematics, to take part in the development of an electronic aid for the blind, and to undertake a certain amount of teaching—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (January 1).

Research Assistant in the Department of Geology—Clerk to the Governors, Chelsea Polytechnic, London, S.W.3 (January 10).

Physicist and Physical Chemist (with at least H.S.C. (science) or equivalent), at the Ministry of Supply Research and Development Establishment, Waltham Abbey, Essex, to undertake laboratory studies of the basic structure and physical properties of plastics, rubbers and fibres, and to assist in applying these materials to Service projects—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.843/54A (January 14).

Lecturer (graduate in chemical engineering or graduate in chemistry with postgraduate training and/or experience in chemical engineering) in Chemical Engineering—The Registrar, College of Technology, Manchester 1 (January 17)

Lecturer/Senior Lecturer in Botany, at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, January 19).

Chair of Agriculture tenable at Wye College—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 27).

Reader in Archæology of the Roman Provinces, at the Institute of Archæology—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 31).

Research Scholar in the Department of Chemistry, for work on problems connected with aluminates—The Secretary, The University, Aberdeen (January 31)

Henry and Charlotte Payne Research Fellowship in cytology and/or cyto-chemistry, with special reference to malignant cells—The Assistant Secretary, The Royal Society, Burlington House, Piccadilly, London, W.1 (February 1).

Lecturer (graduate in science or agricultural science) in Botany, at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, February 1).

Professor of Physics in the Newcastle Division of the University of Durham, and a Professor of Physics in the Durham Colleges in the University of Durham—The Registrar, University Office, 46 North Bailey, Durham (February 12).

Chair of Physics—The Registrar, The University, Hull (February 28).

Agricultural Education Officer (with a degree in agriculture and experience in teaching) in Basutoland, to take administrative and academic charge of a new training centre for subordinate staff of the Agricultural Department—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD 63/76/07.

Assistant Experimental Officers in the Department of Scientific and Industrial Research, Headquarters, Intelligence Division, for abstracting and technical information work—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.113/54A.

Assistant Professor (with a special interest in low temperature research) in the Department of Physics—Prof. W. H. Watson, University of Toronto, Toronto, Canada.

Lecturer or Assistant Professor in Mathematics—The Chairman, Department of Mathematics, McMaster University, Hamilton, Ontario, Canada.

Melville Wills Chair of Botany—The Registrar, The University, Bristol 8.

Physicist, Scientific Officer grade (with an interest in physics of the solid state, and preferably electronics experience) in the Radio Division, Royal Aircraft Establishment, Farnborough, Hants, to study the application of titanate ceramics and similar materials to radio frequency problems; and an Electrical Engineer or Physicist, Senior Scientific Officer or Scientific Officer grade (with a first- or second-class honours degree or equivalent, and for the senior grade at least three years postgraduate research experience), for research on special radio transmitting systems, in particular concerned with microwave region and with studies of modulation characteristics and frequency spectra—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.353/54A

Physicist, Senior Scientific Officer or Scientific Officer grade (with a first- or second-class honours degree in physics, and preferably with some experience of methods of fast neutron flux measurement, and an interest in the development of fast neutron counters), for experimental work in neutron physics—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 322/WGE/2.

Physicist (with a good honours degree), for work concerned with the physical principles (excluding electronics) and incidental problems associated with the development and manufacture of scientific instruments—The Director, British Scientific Instrument Research Association, "Sira", Southill, Elmstead Woods, Chislehurst, Kent.

Physicists or Physical Chemists (with a good honours degree, and preferably with some research experience), for work which will involve both fundamental and applied research on textile fibres and related materials—Appointments Officer, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester.

Research Assistant (with a degree in physics or chemistry) in the Department of Colloid Science, to develop and maintain techniques applied to the investigation of macromolecules in solution (for example, sedimentation, diffusion, light scattering, etc.)—Dr. P. Johnson, Department of Colloid Science, The University, Cambridge.

Scientific Officer (with a first- or second-class honours degree in naval architecture, or alternatively in physics or mathematics with an interest in fluid dynamics), at the National Physical Laboratory, Teddington, for general research in the Ship Division—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.826/54A.

Senior Lecturer in Mechanical Engineering, at the Technical College, Bradford—Director of Education, Town Hall, Bradford 1.

Senior Lecturer (with sound experience in teaching and research at a university or a comparable level) in Animal Husbandry—The Registrar, Wye College (University of London), Ashford, Kent.
